Human Considerations Proxies

The term human considerations is used to address the interests of stakeholders. These include the authorized purposes as well as the many other services afforded by the System. The Corps and USFWS have worked closely with the Missouri River Recovery Implementation Committee (MRRIC) since January 2013 to identify the underlying stakeholder interests referred to as human considerations. Human considerations to be assessed when evaluating alternatives are rooted in the economic, social, and cultural values associated with the natural resources of the Missouri River. The MRRIC represents management of these interests. In January 2013, the Corps asked the MRRIC and their constituent stakeholders to provide input on the human considerations relative to their use of the Missouri River and its resources. The Corps requested this feedback to help inform how MRRIC collective interests could be considered in an assessment of consequences associated with management actions for the listed species. The MRRIC formed the Human Considerations Ad Hoc Working Group as a mechanism to provide input on human considerations. The working group gathered and reviewed input from MRRIC members on the following categories: agriculture; commercial dredging; environmental conservation / fish and wildlife; flood risk management; irrigation; hydropower; local government; navigation; recreation; Tribal and cultural; water quality and water supply; thermal power; and wastewater.

The MRRMP-EIS project delivery team (PDT) developed a suite of models for use in assessing the effects of management actions and alternatives to the human considerations. A subset of these models was used to calculate “proxy metrics” for the human considerations. Proxy metrics were used in the alternatives development process to inform ProACT discussions with MRRIC (Table A-1). Proxy metrics were developed to be efficiently modeled and calculated, responsive to changes in reservoir operations and/or channel geometry modifications, and indicative of the potential for impacts to a human consideration. In most cases, the proxy metrics were not representative of the complete impacts analysis as presented in this draft MRRMP-EIS. Additional economic models were developed to facilitate impacts analysis of each alternative carried forward for detailed consideration in this draft MRRMP-EIS. These economic models were also the basis for calculation of National Economic Development (NED) and Regional Economic Development (RED) effects consistent with Corps planning requirements. The models used to evaluate each human consideration are described in a series of technical reports that accompany this draft MRRMP-EIS.

Round 1 and 2 Proxy Results

The human considerations proxies were calculated for the Round 1 and 2 bird alternatives. These results were used to facilitate trade-off discussion with MRRIC held in May and August of 2015.

TABLE A-1. HUMAN CONSIDERATIONS PROXY METRICS USED IN THE PROACT PROCESS WITH THE MISSOURI RIVER RECOVERY IMPLEMENTATION COMMITTEE

Human Consideration (Interest Category)	Proxy Metric	Units	Description
Agriculture	Peak flows and stages during flood events, and also duration of high stages for interior drainage analysis	Annual and seasonal number of days damage thresholds are exceeded	Change in number of days per year and per season that damage thresholds would be exceeded.
Commercial Dredging	Average annual change in sediment accumulation rate	Tons/year	The base year is 2013 for the sediment modeling, and the model is run forward 50 years. Evaluation will be conducted on how the change in sediment accumulation over the 50-year period differs from on potential alternative versus another potential alternative.
Environmental Conservation / Fish and Wildlife	Change in aquatic / floodplain habitat	Acres	Change in acres of all native habitat types for the baseline condition to each alternative condition.
	Acres of wetland habitat classes	Acres	Acres of wetland habitat classes potentially occurring under each alternative.
	Total # of occurrences of flows below 9,000 cubic feet per second (cfs)	Number of occurrences	Number of occurrences that a flow of 9,000 cfs or less occurs in the Fort Randall to Gavins Point Dam reach based on daily or hourly timesteps.
Flood Risk Management	Peak flows and stages during flood events, and also duration of high stages for interior drainage analysis	Annual and seasonal number of days damage thresholds are exceeded	Change in number of days per year and per season that damage thresholds would be exceeded.
Irrigation	Intake operating conditions	Number of days water surface elevation falls below normal operating conditions	This unit of measure will determine the number of days per year that an irrigation intake along the Missouri River will function below a normal operating level under a given alternative scenario versus the No-Action Alternative. These days are averaged and presented by county.
Hydropower	Total seasonal generation	Generation (MWh)	Seasonal generation (summer, winter).
Local Government	Number of acquisition acres per mile	Acres/mile	For a given alternative, an estimate of the number of acres/mile planned for acquisition.

Human Consideration (Interest Category)	Proxy Metric	Units	Description
Navigation	Number of days per year during the navigation season when at least minimum service is supported by operations	Days/year	Minimum service level refers to when there is approximately an 8-foot depth in the Missouri River navigation channel.
	Number of days per year during the navigation season when operations supports navigation at or above full service levels	Days/year	Full service is when there is a 9-by-300 foot channel in the Missouri River navigation channel.
	The length of the season as measured by the number of days per year navigation is supported by operations during the season; Measured at system level	Days/year	The navigation season on the Missouri River is limited to the normal ice-free period with a full-length flow support of 8 months.
	Number of days per year during the possible navigation season when at least minimum service occurs at one of four target locations (Sioux City, Nebraska City, Omaha, and Kansas City)	Days/year	Minimum service level refers to when there is approximately an 8-foot depth in the Missouri River navigation channel.
	Number of days per year during the possible navigation season when at or above full service occurs at one of four target locations (Sioux City, Nebraska City, Omaha, and Kansas City)	Days/year	Full service is when there is a 9-by-300 foot channel in the Missouri River navigation channel.

Human Consideration (Interest Category)	Proxy Metric	Units	Description
Recreation	Number of days with operate boat ramps	Average number of days/year; Number of boat ramp days/year	Operable boat ramps are when stages and elevations fall between minimum and maximum normal boat ramp elevations during four seasons: spring, summer, fall, and winter.
	Number of chutes, backwaters, or shallow water habitat (SWH) areas	Numbers	The number of chutes or number of SWH areas provide a proxy for recreation in terms of potential opportunities for recreational access, slower river water velocities, and safety.
	Number of days above the conservation pool elevation, the mid-2000s drought elevation, and an elevation between these elevations at upper three reservoirs	Number of days/year	Conservation pool elevations represent important elevations to support both access and fisheries health. Drought pool elevations from the mid-2000s represent important elevations to evaluate how severe drought affects access and fisheries health effects. The pool elevations between the conservation pool and drought elevations represent important elevations to evaluate alternatives. Four seasons are evaluated: spring, summer, fall, and winter.
	Normal to improved fishing success at three upper reservoirs	Number of years criteria are met	Fishing success is defined at upper three reservoirs through rising spring reservoir elevations and the onset of drought.
Tribal and Cultural	Sites at risk	Average number of days at which the water-surface elevation puts cultural resource sites at "high" or "very high" risk	This unit of measure will determine the average number of days per year that each cultural resource site along the Missouri River is subject to higher than normal risk, given an alternative scenario versus the No-Action Alternative.
Water Quality and Water Supply	Intake operating conditions	Number of days below normal operating elevations	This unit of measure will determine the number of days per year for each year over the period of record that a water supply intake along the Missouri River will function below a normal operating level under a given alternative scenario versus the No-Action Alternative.

Human Consideration (Interest Category)	Proxy Metric	Units	Description
Thermal Power	Intake elevations	Number of days per year when river and reservoir elevations are below critical intake operating elevations by power plant location, evaluated annually and for peak summer and winter periods	Sum of number of days per year when river and reservoir elevations are below intake elevations annually and in the peak summer and winter periods.
	Critical low-flow elevations	Number of days per year below the critical low flow condition by power plant location, evaluated annually and for peak winter and summer periods	Sum of number of days per year below critical low flow condition annually, and in the peak summer and winter months.
	Water temperature	Number of days per year when river water temperature is above temperature threshold by power plant location, evaluated annually and for peak summer and winter periods	Sum of number of days per year when water temperature is above temperature threshold annually and in the peak summer and winter months.
Wastewater	Low-flow conditions	Low-flow conditions in cfs calculated by facility location	Calculated the low-flow conditions at each power plant location under the alternatives to compare the changes in low flow conditions under the action alternatives.

RE: Planning Aid Letter Regarding Task B2 in the Missouri River Recovery Program Fish and Wildlife Coordination Act Scope or Work – Fiscal Year 2014

Dear Ms. Fitzner:

The U.S. Fish and Wildlife Service (Service) provides this planning aid letter (PAL) regarding the development of the U.S. Army Corps of Engineers' (Corps) Missouri River Recovery Management Plan (Management Plan) and associated Environmental Impact Statement (EIS) in accordance with the Fiscal Year (FY) 2014 Fish and Wildlife Coordination Act (FWCA) scope of work (SOW), Task B2 (Purpose and Need). As a cooperating agency on the Management Plan and EIS, the Service provides the following pursuant to the FWCA of 1958, as amended (48 Stat. 401; 16 U.S.C. 661 et seq.), the NEPA of 1969 (42 U.S.C. 4321-4347), and the Endangered Species Act (ESA) of 1973, as amended (87 Stat. 884; 16 U.S.C. 1531 et seq.).

This PAL does not constitute the final report of the Secretary of the Interior as required by Section 2(b) of the FWCA, nor does it constitute reconsultation of the 2000 and 2003 Amended Biological Opinion on the Operation of the Missouri River Main Stem Reservoir System, Operation and Maintenance of the Missouri River Bank Stabilization and Navigation Project (BSNP), and Operation of the Kansas River Reservoir System (BiOp) under section 7 of the ESA.

The Management Plan provides a tremendous opportunity for the Corps to objectively consider the results of its ongoing actions to: (1) implement the BiOp; (2) assess recent scientific findings regarding the life history of the three federally listed species; (3) review progress to address impacts to, and recovery of, Missouri River habitats and river processes; (4) incorporate human interests; (5) utilize this knowledge while working transparently with Missouri River basin stakeholders and the Service to develop innovative and contemporary actions to achieve species conservation; and (6) remove impediments to implementation of these actions in order to realize a sustainable Missouri River ecosystem.

Service Perspective on Purpose and Need

Purpose

The Service believes it is important for the Corps to better define the purpose for the Management Plan. It remains unclear to the Service whether the purpose of the Management Plan will be to prepare a new project description on how the Corps will meet its ESA responsibilities, or to develop an adaptive management (AM) strategy for the Missouri River Recovery Program (MRRP).

Congress directed in section 7 of the ESA that all federal agencies “7(a)(1)...use their authorities in the furtherance of the purposes of this Act by carrying out programs for the conservation of endangered species and threatened species...” and that all federal agencies “7(a)(2) ensure that any action ... authorized, funded, or carried out... was not likely to jeopardize a listed species or cause destruction or adverse modification of critical habitat.” Accordingly, we recommend the Management Plan re-evaluate past and ongoing operations of the Missouri River system in relation to threatened and endangered species and determine if there are different operational scenarios, along with AM, that would achieve these purposes. These operations should seek to be more scientifically informed and cost effective, while addressing the jeopardizing effects of the Missouri River operations as currently implemented.

The Service views the purpose of the Management Plan as the development and eventual implementation of a fully functioning AM program as included in the 2003 BiOp reasonable and prudent alternative (RPA). AM involves formulating alternative actions to meet measurable objectives, predicting the outcomes of alternatives based on current knowledge, implementing one or more alternatives, monitoring the effects, and then using the results to improve knowledge and adjust actions accordingly.

With that in mind, the Service recommends the purpose description within the Management Plan recognize the need to develop an ecologically viable, resource efficient, legally defensible AM program that provides for the basic life requisites of listed species while maintaining the authorized purposes of the Missouri River system.

Need

After review of the Need section in the Management Plan, the Service believes that it would benefit from a reorganization. The section could be parsed out into three sub-sections: (1) historical overview; (2) current status of the ecosystem and species; and (3) what the Corps has done to meet its ESA obligations under previous BiOps and how that leads us to development of this Management Plan.

Much of the information needed for sub-sections (1) and (2) already exists and can be incorporated into development of the Need section. Together, these sections would “tell a story” of how the Missouri River ecosystem became imperiled, the current status of the system and its species, and how the Corps is remedying this by mitigating for fish and wildlife habitat losses using various authorities.

For the historical overview, a more comprehensive discussion of the historical events that have led up to the “*need for the Corps to take action and develop the Management Plan*” is needed. We recommend this section include how the construction of the Mainstem Dam system (Flood

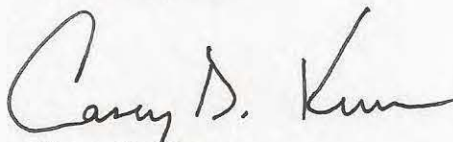

Control Act of 1944) on the Missouri River, as well as other development (including implementation of the BSNP) by the Corps, has come at the expense of the river's native fish and wildlife. The reader should finish reading this section with no doubt as how the conditions on the Missouri River necessitate action by the Corps.

For the sub-section detailing current ecosystem and species status, the Corps has already included an overview of the circumstances (historical and current) that have led to the precipitous decline in the pallid sturgeon, piping plover and interior least tern. The Service would recommend including some type of overview of habitat losses (they are partially interwoven in to the species status paragraph), perhaps in a table format and then also relocating Table 1-1 (Decline in Native Species) to this sub-section as well.

Finally, the Need section would also benefit from a simplification of Section 3.2.4 (Acquisition and Development of Land Needed for Creation of Habitat). As is, the section while informative regarding how the Corps is mitigating for lost fish and wildlife habitat, is also mired down in a complex discussion of different authorities, acreage requirements and percent reductions in native wildlife. The overview on page 10 is lengthy and tends to overshadow the actual discussion of "need." The section could be improved with a simple discussion of what the Corps has done and is doing (per different authorities) to mitigate for the adverse impacts to the natural Missouri River ecosystem and the loss of habitat for both native and federally listed species.

The Service looks forward to our continuing collaboration with the Corps and other conservation partners in support of this important effort. State Fish and Wildlife agencies were contacted and informed of the recommendations that the USFWS was making to the USACE regarding Purpose and Need. To date no comments have been received. We believe a Programmatic Management Plan with a well-designed adaptive management program is critical to ensuring the success of the program, and the conservation of the fish and wildlife resources of the Missouri River. If you have any questions, please feel free to contact me at (605) 665-4856.

Sincerely yours,

RE: Planning Aid Letter Regarding the
Appendix A of the Adaptive Management
Plan: Adaptive Management Governance

Dear Ms. Fitzner:

The U.S. Fish and Wildlife Service (Service) provides this planning aid letter (PAL) regarding the development of the U.S. Army Corps of Engineers' (Corps) Missouri River Recovery Management Plan (Management Plan) and associated Environmental Impact Statement (EIS) in accordance with the Fiscal Year 2015 Fish and Wildlife Coordination Act (FWCA) scope of work. As a cooperating agency on the Management Plan and EIS, the Service provides the following comments in coordination with the seven Missouri River mainstem state fish and wildlife agencies pursuant to the FWCA of 1958, as amended (48 Stat. 401; 16 U.S.C. 661 et seq.), the NEPA of 1969 (42 U.S.C. 4321-4347), and the Endangered Species Act (ESA) of 1973, as amended (87 Stat. 884; 16 U.S.C. 1531 et seq.). Enclosed are emails from three state fish and wildlife agencies, Nebraska Game and Parks Commission, the Iowa Department of Natural Resources, and Kansas Department of Wildlife, Parks and Tourism, containing their comments.

This PAL does not constitute the final report of the Secretary of the Interior as required by Section 2 (b) of the FWCA, nor does it constitute reconsultation of the 2000 and 2003 Amended Biological Opinion on the Operation of the Missouri River Main Stem Reservoir System, Operation and Maintenance of the Missouri River Bank Stabilization and Navigation Project (BSNP), and Operation of the Kansas River Reservoir System (BiOp) under section 7 of the ESA.

The following comments are specifically in regards to the draft Appendix A: Adaptive Management (AM) Governance document. They are a compilation of comments provided by the three state agencies listed above and Service staff.

General Comments

The Service is pleased that a governance plan is being included in the management plan. Such a document will allow other entities, including the public, to understand how the decisions will be made during implementation of the Management Plan. Overall, the document is coming together

well and will provide a means for the implementation phase of the process. At the same time, we have a few concerns and recommendations listed below to improve the Management Plan, and its comprehensive approach.

The governance document fails to adequately recognize the statutory and constitutional responsibilities of the state fish and game agencies and Tribes throughout the decision making processes. Just as the federal government has certain responsibility for various natural resources, so do the state fish and game agencies and Tribes. The document should address the Corps' responsibilities to coordinate with the Tribes through government-to-government consultation as directed by Federal statutes or administrative actions such as Executive Order (EO) 13175, and agency policies. Not only does the Corps have statutory (FWCA) responsibilities to coordinate with state fish and game agencies; each state also has responsibilities, through various federal and state statutory and constitutional authorities, for management of water quantity, water quality, and fish and wildlife resources within their boundaries that could be affected in this process (in either a positive or negative way). State fish and game agency and tribal consultations throughout the AM process will help ensure that future Federal actions are achievable, comprehensive, long-lasting, and reflective of state and Tribal input.

Failure to fully inform and involve the state fish and game agencies and Tribes has the potential to slow recovery of the currently listed species as well as the overall system if unintended conflicts occur due to failure to adequately engage them in the process. We recommend that the state fish and game agencies and Tribes be included in the governance document.

The governance document presents a confusing description of the AM governance or decision making structure and process. It appears that there are six tiers of information processing and/or decision making: 1) an Oversight Team, 2) an Oversight Sub Team, 3) a Management Team, 4) a Management Sub Team, 5) a Technical Team, and 6) finally a Technical Sub Team. Figure 1, however, suggests that there are three tiers. The document should be revised to ensure a consistent message/ process is presented.

Adding to the confusion for the reader, terms are not used consistently throughout the document. For example on pages 3-4, the headings describe three **Sub**-Teams [Oversight **Sub**-Team (OT), Management **Sub**-Team, Technical **Sub**-Team (TT)]; then in Figure 1 the same acronyms are used (OT, MT, and TT) but the use of **Sub** has been dropped from the names for these teams [e.g. Oversight Team (OT)]. The description of the team membership in Figure 1 does not match that described in the text that precedes the figure. For example, page 2 describes the Oversight Team as the Corps Division and Service Regional Director, whereas Figure 1 has different description of the team membership for the Oversight Team.

If the intent is truly to have six tiers, this may prove to be a very inefficient, redundant, and unmanageable composition that will likely result in cumbersome decision making and implementation. The Colorado River Recovery has a three tiered process (multiple technical teams, a management team, and implementation team (SES level agency representatives) that works very well.

Specific Comments

Page 1 and 2, Categories of Decision Making. The document suggests that certain categories will only be handled by specific tiers. Although this may be the standard process, programmatic decisions may have to be made at the Oversight level, when agreement cannot be reached at the Management Team level.

Page 2, last sentence of top paragraph. This sentence describes the composition of the Oversight Team. The document needs clarification on who is the Corps representative (the whole Division and the Service Regional Director or one person and the Service Regional Director).

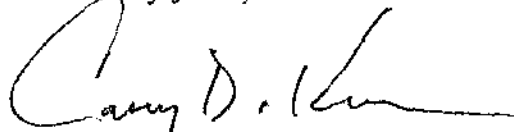

Page 2, Table 1, and Figures 1 and 2. In the three tiers of decisions, project specific design and implementation appear to be missing. They are not policy, or programmatic, or monitoring. They are designing and building habitat. Those types of decisions and who will be included in those decisions need to be included in the text and in Figures 1 and 2. Those types of action decisions should have significant involvement by our state fish and game agency partners and Service field staff (i.e. ES FOs, refuges, fisheries). We recommend adding a section to show how states and tribes are included in the process. The Governance structure would benefit with some discussion of the complementary processes also required for Corps projects. That could provide a better understanding of the way the Corps intends to integrate input from the various agencies, groups, and partners beyond MRRIC.

Page 3. It appears in the document that the management sub-team is the implementation entity and that the two federal agencies will coordinate through Missouri River Recovery Implementation Committee on project implementation. Historically, it has been the role of the state fish and game agencies to assist in putting projects on the ground. It is important to ensure there is no disconnect between the field and the various organizational levels in the AM governance structure. We recommend including the state fish and game agencies in this discussion as well.

Page 4, Technical Sub-Team section. The second sentence of this section states "the TT consists of three teams of scientists.....;" however, four teams are listed.

The Service, in coordination with Missouri River mainstem state fish and wildlife agencies, is looking forward to continuing to work collaboratively in support of this important effort to ensure the success and ultimate implementation of the Management Plan for the recovery of the fish and wildlife resources of the Missouri River, while also taking into consideration the human resources. If you have any questions, please feel free to contact me at (605) 665-4856.

Sincerely yours,

To: "NelsonStastny, Wayne" <wayne_nelsonstastny@fws.gov>

Wayne,

Thanks for sending the AM document out for review. Since the states have public trust responsibilities for fish and wildlife species, it appears to me the document should include more involvement from state fish and wildlife agencies in the basin since we have expertise in many fish and wildlife topics and managers on the landscape. I only saw the word mitigation one time and since this program has Congressional authority to purchase 167,000 acres of land, especially within the accretion zone below Sioux City, the probability of bringing health back to the river sooner as well as the health of listed species is greater if everyone keeps this in mind.

Subject: Re: FWCA Adaptive Management Governance Document for review

Wayne:

Thank you for the opportunity to review these documents. We have reviewed the documents associated with the Adaptive Management Governance process that proposes a structure for decision making and responsibility of various federal agencies and interests. First, we want to clarify the intent of these documents. It appears these documents outline the decision process related to Adaptive Management related actions associated with the overall recovery effort, not just interaction with MRRIC. Is that correct? With that as the context, the issue of concern to us is these documents appear to fail to recognize the statutory and constitutional responsibilities of the states and adequately include the states throughout the decision making processes. Just as the federal government has certain responsibilities for various natural resources, so do the states. Through various statutory and constitutional authorities, each of the states have responsibilities for the management of water quantity, water quality, and fish and wildlife resources within their boundaries that could be affected in this process (in either a positive or negative way).

Failure to fully inform and involve the states has the very real potential to slow recovery of the currently listed species as well as the overall system if unintended conflicts occur due to failure to adequately engage the states in the process. We would urge the federal agencies to correct this deficiency before these documents are finalized.

31 JUL 2015

Noreen Walsh
U.S. Fish and Wildlife Services
134 Union Blvd
Lakewood, CO 80228

Dear Noreen:

As we have discussed, this letter confirms our mutual understanding that the U.S. Army Corps of Engineers (Corps) and the U.S. Fish and Wildlife Service (Service) are engaged in consultation on the 2003 Amended Biological Opinion on the Operation and Maintenance of the Mainstem Missouri River Reservoir System, the Missouri River Bank Stabilization and Navigation Project, and the Kansas Reservoir System (2003 Amended BiOp). The Missouri River Recovery Management Plan and Environmental Impact Statement (MRRMP/EIS), which is currently being developed jointly by our agencies in collaboration with the Missouri River Recovery Implementation Committee (MRRIC), serves as the on-going medium for this consultation. Following release of the draft MRRMP/EIS for public review and comment in 2016, this document will provide the foundation for a revised Biological Assessment (BA) and proposed action for our operation of the Missouri River System. Subject to the conclusions of the revised BA, we anticipate the Service may amend the current BiOp or issue a new BiOp pursuant to regulations governing section 7 of the Endangered Species Act (ESA). Based on this process and public input, the Corps will then be poised to make any appropriate revisions to the draft MRRMP/EIS, issue a final decision, and begin implementation.

The Missouri River Recovery Program's Independent Science Advisory Panel (ISAP), tasked by MRRIC, released a report (Final Report on Spring Pulses and Adaptive Management) on November 30, 2011 that analyzed the efficacy of the managed spring pulse releases from Gavins Point Dam as implemented by the Corps in response to the 2003 Amended BiOp. The ISAP's report identified the need to review the current management actions being taken to benefit the listed species in light of the current state of the science, concluding that there was "substantial new knowledge regarding pallid sturgeon, least tern, and piping plover, their habitats, and management opportunities on the lower Missouri River" since the 2003 Amended BiOp was published (pg 57). The ISAP recommended a "new management agenda using hydrological manipulations and habitat construction activities, implemented in an adaptive management framework" to replace the current action plan (pg 4). To achieve that goal, the panel provided a set of specific guidance and suggestions for the agencies to pursue (pg 4-5). The report also provided recommendations for developing an overarching Adaptive Management (AM) program to systematically address uncertainties involved with implementation of the management actions. As you know, development of an AM plan is also a component of the 2003 Amended BiOp.

On February 21, 2012, the MRRIC supported that guidance and provided our agencies with a formal consensus recommendation, in accordance with their Charter, proposing seven specific actions for the agencies to implement to fulfill the ISAP recommendations. On May 8, 2012, the Corps and Service provided a joint response to the MRRIC's recommendation, endorsing the ISAP's report and expressing our agencies' joint commitment to working closely with the MRRIC to implement the recommended actions.

To implement the ISAP report's recommendations, and in coordination with and building on the corresponding set of recommendations from the MRRIC, our two agencies have been applying a structured scientific process, employing teams of nationally recognized experts, to:

- Complete an Effects Analysis (EA) that includes review and compilation of the best available scientific information,
- Develop Conceptual Ecological Models (CEMs) for the three listed species to articulate the stressors and mitigative actions on species performance ,
- Identify the factors that might be limiting species' success,
- Evaluate a suite of management actions with the potential to remove those limiting factors, including any impacts that may accrue to human considerations,
- Design an overarching AM plan with clear decision criteria and robust and integrated research, monitoring and assessment activities,
- Assess and make appropriate changes to management actions through a management plan for continued compliance with ESA requirements, and
- Demonstrate commitment to implementing that management plan by completing all necessary components to its development, including National Environmental Policy Act (NEPA), Corps' Independent External Peer Review (IEPR), and Fish and Wildlife Coordination Act (FWCA).

Over the past three years, our agencies have invested significant time and resources toward implementing the recommendations and have made tremendous progress.

- The Notice of Intent for the MRRMP/EIS was published in January 2013 following extensive collaboration between our agencies on the study's Purpose and Need.
- The Request for Proposals for the Effects Analyses work was developed jointly by our agencies, reviewed by the ISAP and the MRRIC, and issued in March 2013. Nationally respected experts from the U.S. Geological Survey (pallid sturgeon), Pacific Northwest National Laboratories (least tern and piping plover), and the Corps' Engineer Research

and Development Center (river geomorphology) were selected to lead the EA teams and began work immediately.

- At the suggestion of the Service, a group of key team members, including the Corps, Service, and the Chair of the MRRIC, attended a Structured Decision Making Workshop at the National Conservation Training Center in June 2013 to strengthen our ability to conduct such a complex undertaking as the MRRMP/EIS with such a large and diverse group as the MRRIC.
- Evolving through a series of interim products that were guided by ISAP reviews and feedback, the CEMs for the three species were completed in February 2014.
- At the MRRIC's request, and with our agencies' concurrence, an independent socio-economic panel of experts was selected in April 2014 to provide review and feedback on the economic evaluation of potential MRRMP/EIS alternatives. The three-member Independent Social Economic Technical Review (ISETR) panel supplements the scientific expertise of the ISAP.
- Draft EAs for the species were completed in October 2014; the documents are currently undergoing pre-publication quality reviews.

Key elements that have been developed as part of the EA process include predictive species models, comprehensive hypotheses sets, evidence-based assessments of those hypotheses, and identification of potential management actions. It is safe to say that the breathtaking amount of state-of-the-science information that has been produced as part of this effort is unprecedented.

We appreciate the Service's continued efforts to utilize the EA results to identify objectives and metrics for the species. As you are aware, the species objectives and metrics are critical to development of appropriate management actions. The clear connection of species objectives and metrics to the rigorous scientific processes being followed by the EA teams (and reviewed by the ISAP and the MRRIC) will ensure success in reaching the goals described above.

Our agencies have been working with stakeholders to evaluate potential management action alternatives that achieve species objectives. This includes analyzing the potential impacts of those management actions on a suite of socioeconomic and other human considerations. We are also working with the EA team leads to draft the AM strategies that will systematically address uncertainties involved with implementation of management actions. And all of this has been accomplished with and improved by continuous review and feedback from the ISAP, ISETR, and the MRRIC.

While there is no doubt that our two agencies, working with the MRRIC, EA teams, and review panels, have accomplished much, there is still work to be done. As our agencies continue to refine management actions, assemble and evaluate alternative plans and potential

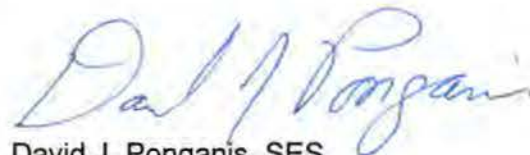

impacts, develop AM strategies, and select a new management plan, we are committed to maintaining continuous engagement with the Service.

As we jointly work to complete the MRRMP/EIS, the Corps continues to implement the Reasonable and Prudent Alternative (RPA) provisions in the 2003 Amended BiOp, working closely with the Service to adaptively manage the RPA elements as appropriate, and as envisioned by the 2003 Amended BiOp. For example, over the past several years, based on new information or changing environmental conditions, our agencies have convened a plenary process with basin stakeholders to develop technical criteria for the spring pulse, worked collaboratively to modify the definition and parameters of Shallow Water Habitat (SWH), and explored modifications to criteria for unbalancing the upper three reservoirs that will benefit the species without adversely affecting the flood control purpose. All of these adjustments to management actions are based on evaluation of habitat, flow, climate, species response and other information as it becomes available, as contemplated in the 2003 Amended BiOp (pg 221).

Our agencies continue to meet regularly through the established Agency Coordination Team (now known as the CORE team) which allows us to evaluate implementation of management actions alongside the status of the species to ensure sufficient progress is always being made toward avoiding jeopardy and that course corrections are made as needed (pg 223). This is nowhere more evident than in the continuous improvements being made in the design, location, and construction of SWH to benefit the pallid sturgeon. The Corps' implementation teams are incorporating the best available pallid sturgeon science into engineering designs to address the factors thought to be limiting sturgeon success. We will also continue to make use of the quarterly MRRMP/EIS In-Progress Review meetings to jointly resolve management decisions as needed.

As we have agreed, and shared publicly on many occasions, the Corps fully recognizes the need to expeditiously complete the path to a new management plan as agreed to above in order to continue fulfilling our obligations under the ESA.

We look forward to our continued collaboration over the next year to achieve that goal.

RE: Planning Aid Letter Regarding the Missouri River Recovery Management Plan
Lower Missouri River Pallid Sturgeon Framework, Targets and Decision Criteria

Dear Ms. Fitzner:

The U.S. Fish and Wildlife Service (Service) provides this planning aid letter (PAL) regarding the development of the U.S. Army Corps of Engineers' (Corps) Missouri River Recovery Management Plan (Management Plan) and associated Environmental Impact Statement (EIS) in accordance with the Fiscal Year 2015 Fish and Wildlife Coordination Act (FWCA) scope of work agreed to by our agencies. The Service provides the following comments pursuant to the FWCA of 1958, as amended (48 Stat. 401; 16 U.S.C. 661 et seq.), the NEPA of 1969 (42 U.S.C. 4321-4347), and the Endangered Species Act (ESA) of 1973, as amended (87 Stat. 884; 16 U.S.C. 1531 et seq.).

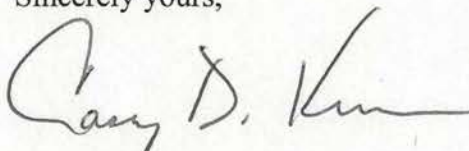

This letter confirms the USFWS support for the Lower Missouri River Pallid Sturgeon Framework, Targets and Decision Criteria, (enclosed), for the Missouri River Recovery Management Plan EIS (MRRMP-EIS). We appreciate the dialogue that has occurred between the Corps and Service staff to date on this effort. We look forward to further discussions to finalize the Level 1 and 2 Components and Decision Criteria.

The Service recognizes the lingering uncertainties regarding the scale and scope of management actions necessary for the Corps to avoid jeopardizing the continued existence of the pallid sturgeon. The Framework document should accelerate the reduction of uncertainty and ultimately lead to a more strategic and focused implementation of appropriate management actions. The acquisition of knowledge and reduction of uncertainty do not, in themselves, constitute avoidance of jeopardy. Avoidance of jeopardy is only achieved through taking action and the Service fully supports the Framework and expects a commitment to a strategy reliant upon a progressive adaptive management (AM) program. The AM program, including this Framework should provide and illustrate a commitment and pathway to the scope of actions, including level 4, necessary to abate the effects of the Federal action and avoid jeopardizing the continued existence of pallid sturgeon on the lower Missouri River. At the same time, the AM decision process should ensure the flexibility to adjust actions, objectives, timelines and decision criteria while maintaining a focus on the fundamental objectives.

The Service acknowledges the ongoing refinement of actions and development of alternatives for the MRRMP-EIS. We anticipate that as the MRRMP-EIS moves forward that the decision criteria outlined in this Framework may need fine-tuning.

We look forward to continued discussions on this topic with the Corps. Please contact me at (605) 665-4856 or Wayne Nelson-Stastny at 605 660-5349 for further questions and clarification. The Service looks forward to our continuing collaboration with the Corps and other conservation partners in support of this important effort.

Sincerely yours,

A handwritten signature in black ink, appearing to read "Casey D. Kruse". The signature is fluid and cursive, with a large initial "C" and a long, sweeping underline.

LMR Pallid Sturgeon Framework, Targets and Decision Criteria

Summary: This draft document outlines the Lower Missouri River pallid sturgeon framework (Framework) with an emphasis on the required implementation targets and decision criteria for management actions at level 3. The criteria outlined below represent a joint USFWS/USACE characterization of the necessary elements for managing uncertainty and associated risks under the Adaptive Management Plan as envisioned, and is intended to guide alternative formulation for the MP-EIS. The Framework is based on four levels of activity. Level 1 and 2 components include, respectively, research and field studies/experiments aimed at resolving critical uncertainties regarding the management actions needed to offset the effects of the Federal action. Management actions at levels 3 and 4 are aimed at avoiding or offsetting impacts of the Federal action by increasing the pallid sturgeon population. The nature and details of actions needed at level 4 remain uncertain, but a suite of level 3 actions organized around four categories have been identified for planning purposes and would be implemented unless certain decision criteria are met. The relevant decision criteria and implementation requirements are summarized in the following sections. It is intended that implementation of the actions through level 4 following decision criteria with associated studies collectively encompassed in the Framework **would** avoid jeopardizing the pallid sturgeon while minimizing unnecessary and potentially impactful actions. Additional details of the Framework will be incorporated into the MRRP AM plan.

Underpinning Principles: Given the lingering uncertainties regarding the scope and scale of the management actions necessary for the Corps to avoid jeopardizing the continued existence of pallid sturgeon, a strategy reliant upon a progressive adaptive management (AM) program is the most effective way to manage risks to the pallid sturgeon. This strategy is evident in the Pallid Sturgeon Framework (Framework) advanced through the Effects Analysis (EA) and further refined by the Corps and Service. The Framework is expected to accelerate the identification of recruitment bottlenecks, resulting in a more strategic and focused implementation of appropriate management actions. This approach has the added benefit of minimizing impacts to stakeholders and avoiding unnecessary implementation costs.

While both the uncertainty and the scale of required actions point to a need for the Framework, the acquisition of knowledge and reduction of uncertainty do not, in themselves, constitute avoidance of jeopardy or directly reduce risks to the species. For these reasons, the Service requires a set of decision criteria to guide execution of the Framework so as to ensure that the knowledge gained results in a thoughtful but rapid progression through the implementation levels to actions providing a meaningful, population-level response of the pallid sturgeon. The intent is that the implementation of this framework through a progressive adaptive management program will be sufficient to abate the effects of the Federal actions and avoid jeopardizing the continued existence of the pallid sturgeon on the lower Missouri River.

The decision criteria (outlined below) include two stipulations that supplement risk management for the species beyond that afforded by AM alone. First, the artificial propagation program would be continued throughout the Framework's implementation, and improvements to that program related to genetic concerns, disease, stocking size, etc., would be pursued consistent with the propagation plan under development for the Recovery Program. Second, implementation of management actions at level 3 for each hypothesis would be required within a specified timeframe, provided the hypotheses associated with the action are not rejected by that time. This stipulation should not be construed to mean that level 3 actions should not or cannot be implemented earlier than the time limits; the criteria below ensure that progression from one level to the next (or possibly skipping one or more levels, rejecting the associated hypotheses, etc.,) would occur as soon as dictated by the metrics and decision criteria outlined at the end of the framework.

The actions at levels 2 and 3 outlined in this framework and in more detail in the AM Plan provide the basis for the Adaptive Management Plan as described and evaluated in the Missouri River Recovery Management Plan and Environmental Impact Statement (MP-EIS)¹. Thus, any of the actions identified as part of this alternative may be implemented in whole or in part, subject to the bounding decision criteria, and other logistical constraints. The scope of implementation for each action is expressed using bounding rates. The overall implementation scope will be established once a sufficient population-level response has been observed to permit development of level 4 targets.

It is important to note that the actions needed to address the pallid sturgeon life requisites remain uncertain and the actions currently outlined in the Framework are subject to change. At any time during the Framework's implementation, it may become apparent that 1) a particular action is not needed, 2) a proposed action requires modification to be effective, or 3) that some new action not previously evaluated is required. In the first instance, the criteria outlined in the AM Plan would permit abandonment of further implementation of associated management actions and describe other lines of study (if any). In the latter two cases appropriate engagement with MRRIC, and/or other requirements or procedures needed for compliance with NEPA may be necessary prior to implementation.

Lower River Pallid Sturgeon Framework: The Framework for the lower river consists of four levels of activity as described in Table 1. The lower river refers to the mainstem Missouri River downstream of Gavins Point Dam, including the influences (to the extent they are relevant) of upstream reservoirs like Fort Randall and Lewis and Clark Lake, influences of major tributaries, and some portion of the Middle Mississippi River.

The studies and other activities at levels 1 and 2 listed herein are described in detail in Appendix C of the AM Plan. These efforts are organized so as to efficiently address the hypotheses identified in the EA. Activities at level 3 identified herein are described further in the MRR MP. They include various management actions aimed at eliciting a population-level response from the pallid sturgeon. Level 4 actions are not presently described but will evolve through implementation of the AM plan. The extent

to which specific studies or actions at any level are implemented will depend upon several circumstances and is guided by the objectives and a set of associated decision criteria.

Table 1. Pallid sturgeon framework for the lower Missouri River

Level 1: Research	Population Level Biological Response <u>IS NOT</u> Expected	Studies without changes to the system (Laboratory studies or field studies under ambient conditions)
Level 2: In-river testing		Implementation of actions at a level sufficient to expect a measurable biological, behavioral, or physiological response in pallid sturgeon, surrogate species, or related habitat response.
Level 3: Scaled Implementation	Population Level Biological Response <u>IS</u> Expected	In terms of reproduction, numbers, or distribution, initial implementation should occur at a level sufficient to expect a meaningful population response progressing to implementation at levels which result in improvements in the population. The range of actions within this level is not expected to achieve full success (i.e. Level 4).
Level 4: Ultimate Required Scale of Implementation		Implementation to the ultimate level required to remove as a limiting factor.

Components, Actions and Decision Criteria for the Pallid Sturgeon Framework: Objectives for the pallid sturgeon have been defined at each of the Framework levels (including means objectives for actions) as well as for the overall program (i.e. the fundamental objectives). For each objective, the AM Plan presents corresponding metrics, decision criteria (performance measures, triggers, etc.) monitoring needs and protocols, and (sometimes) contingency plans. Near-term implementation of the Framework will focus on those objectives outlined for levels 1 through 3 with an increased focus over time on the fundamental objectives and sub-objectives. There are also objectives and associated criteria relating to general program implementation that address concurrent plover, tern and pallid sturgeon considerations.

As information is developed from level 1 and 2 studies or through monitoring of effectiveness of management actions, the Framework's decision criteria will be used to determine when and what action should follow. Decisions might include:

- a) accepting that the scientific information supports the hypothesized action and:
 1. moving to the next most important science question pending for each big question; or
 2. moving to implementation of higher level (i.e. level 2, 3 or 4) actions;
- b) determining that the scientific information does not support the hypothesized action and:
 1. refining the hypothesis and continuing scientific investigations; or
 2. rejecting the hypothesis and promoting an alternative hypothesis that better explains observed information.
- c) to begin implementing at level 3 because a time limit for a hypothesized action has been reached and results remain equivocal (studies at levels 1 and 2 might continue concurrently)

In general, the details of contingent actions are difficult to specify because the scope, scale, timing, distribution, etc., of those actions will depend upon the knowledge gained from previous levels of implementation. However, contingent actions at level 3 that are triggered by the time limits are an exception. These are specified in the form of a required minimum and maximum implementation rate that is to be followed unless and until knowledge gained from those actions and from previous and ongoing studies at levels 1 and/or 2 demonstrate that a different rate is required.

Level 1 and 2 Components and Decision Criteria: Levels 1 and 2 include activities focused on increasing the state of scientific knowledge about the factors most likely limiting pallid sturgeon survival and are intended to systematically and efficiently address critical uncertainties regarding what management actions are needed to address impacts of the Corps' Missouri River operations on pallid sturgeon. Level 1 and 2 studies are directly tied to those uncertainties and management hypotheses highlighted in the Effects Analysis that, if resolved, could significantly affect the implementation of management actions. They can continue concurrently with level 3 efforts, but are generally intended to inform actions at level 3. Although level 2 studies have learning as a primary objective, they can also provide measurable benefits to pallid sturgeon populations and, in such cases, would be counted toward targets in the same manner as level 3 actions. Criteria for accepting or rejecting specific hypotheses, for assessing the results of scaled experiments, and for moving from level 1 to level 2 or level 2 to level 3 actions are described in Appendix C of the AM Plan. A summary is presented in Table 2.

Table 2. Summary of decision criteria associated with level 1 and 2 studies.

Question, Level and Study Components	Metrics and Decision Criteria
Big Question 1:Spawning Cues	
L1/C1-Design complementary passive telemetry network	
L1/C2 - Opportunistic tracking or reproductive behaviors	
L1/C3 - Mesocosm experiments, reproductive behaviors	
L2/C4 - Engineering study effects on other authorized purposes	
L2/C5 - Experimental flow releases, Gavins Point	
Big Question 2:Temperature Control	
L1/C1 – Model water temperature management options, Gavins Point	
L1/C2 - Field studies temperature and reproductive behaviors, surrogates	
L1/C3 - Mesocosm studies temperature and reproductive behaviors	
L2/C4 - Field tests of water temperature management, Gavins	

Point	
L2/C5 - Experimental warm water releases, Gavins Point	
Big Question 3: Food and Forage	
L1/C1 - Screening: limitations of food or forage habitats	
L1/C2 - Technology development for IRC sampling, modeling, measurement	
L1/C3 - Field studies along gradients, food and forage habitats	
L1/C4 - Mesocosm studies: quantitative habitat-survival relations	
L2/C5 - Design studies for IRC experiments	
L2/C6 - Manipulative field experiments with IRCs	
Big Question 4: Drift Dynamics	
L1/C1 - Technology development surrogate particles, particle tracking	
L1/C2 - Resilience, stamina in turbulent flows	
L1/C3 - Field studies on free embryo exit paths	
L1/C4 - Field gradient study, age-0 survival and complexity	
L1/C5 - Free embryo transport to Mississippi River	
L1/C6 - Field experiments with particle tracking, embryos, models	
L2/C7 - Engineering designs for interception experiments	
L2/C8 - Field experiment: discharge and dispersion	
L2/C9 - Field experiment: IRC complexes	
Big Question 5: Spawning Habitat	
L1/C1 - Study of functional spawning habitat, Yellowstone River	
L1/C2 - Field gradient study, habitat conditions LMOR	
L1/C3 - Mesocosm studies on spawn conditions, behaviors	
L2/C4 - Engineering studies for sustainable design	
L2/C5 - Manipulative field experiment for spawning habitat	

Big Question 6:Population Augmentation	
L1/C1 - Engineering feasibility hatchery needs, facilities, operations	
L1/C2 - Retrospective study survival linked to hatchery operations	
L1/C3 - Simulation models, population sensitivity to size, health, genetics	
L2/C4 - Field experimentation with varying size, location of stocking	

Level 3 Actions, Targets and Decision Criteria: Requirements for level 3 were developed collaboratively by the USACE and USFWS and reflect both best available science and policy considerations. The nature, scope and implementation timeframe of management actions at level 3 outlined in this document are intended to 1) provide a commitment and pathway to the scope of actions (including at level 4) necessary to abate the effects of the Federal action and avoid jeopardizing the continued existence of the pallid sturgeon on the lower Missouri River, 2) afford an opportunity for study and learning while also ensuring risks to the pallid sturgeon are managed, and 3) serve as a basis for the range of actions to be assessed as part of the MP-EIS. Further refinement of the accompanying decision criteria and added detail will be developed through subsequent interagency discussions as part of development of the AM Plan. The AM decision process will ensure the flexibility to adjust actions, objectives, timelines and decision criteria while maintaining a focus on the fundamental objectives. This flexibility will be assessed through analysis of several scenarios that highlight need for change; the scenarios will be addressed with both internal and external parties, including the MRRIC ad hoc work groups.

Implementation of management actions at level 3 for any limiting factor would commence at the earlier of two triggers: 1) within two years of affirmative results from level 1 and/or 2 studies indicating an action is needed for a limiting factor, or 2) the established time limits should the results of studies/tests at levels 1 and 2 of the associated hypotheses remain equivocal. The first trigger might be affected by the criteria summarized in Table 2 and presented in detail in the AM Plan appendices. In many cases, definitive criteria for accepting or rejecting hypotheses are not readily identifiable, or the available data is not likely to provide unequivocal results. In those situations, a lines-of-evidence approach may be applied.

To help find an appropriate balance between taking action versus decreasing uncertainty, a series of five questions (Table 3) were developed as a proposed checklist to guide decisions to advance to implementation at level 3 for any of the hypotheses identified by the EA. If all five questions can be answered “Yes”, advancement to Level 3 implementation would be triggered. If an affirmative answer to four of the five questions exists and either question 1 or question 2 is equivocal, implementation of level 3 management actions would be triggered within two years (unless the hypothesis is rejected in that timeframe). The five questions are listed in Table 3.

Table 3. Supplemental lines of evidence strategy for triggering level 3 implementation.

Question		Y	U	N
1	Is this factor limiting pallid sturgeon reproductive and/or recruitment success?			
2	Are pallid sturgeon needs sufficiently understood with respect to this limiting factor?			
3	Do one or more management action(s) exist that could, in theory, address these needs?			
4	Has it been demonstrated that at least one kind of management action has a sufficient probability of satisfying the biological need?			
5	Have other biological, legal, and socioeconomic considerations been sufficiently addressed to determine whether or how to implement management actions to Level 3?			
Criteria for level 3 implementation				
1 - A "Yes" to all five questions triggers level 3 implementation				
2 - A "Yes" to four of five, with an "Uncertain" for either #1 or #2 triggers a two-year clock to either reject the hypothesis or implement at level 3				

Table 4 lists the actions currently defined for the Lower basin pallid sturgeon and evaluated under the MP-EIS. In the absence of affirmative results from level 1 and 2 studies or the lines-of-evidence analyses, the time limit column in the table reflects the latest point in time (in years after the Record of Decision) to initiate the listed actions. Targets are defined in terms of implementation rates, and the acceptable range is shown by the Minimum and Maximum Scope columns. For example, if the ROD is signed in 2016, the IRC habitat actions (time limit 2 years) must begin no later than 2018, and are to be implemented at a rate of 260-500 new ac-day/yr of IRC habitat (note that these values are placeholders until actual targets are calculated). Progress toward the targets will be determined by field measurement of project outcomes (as part of the monitoring program), and could be derived from either Level 2 or Level 3 actions. The implementation scope could deviate from that described below as dictated by the results of level 1 and/or 2 studies. However, management actions outside the scope of that evaluated under the MP-EIS would require additional (i.e. supplemental) environmental assessment and coordination with MRRIC.

Table 4. Summary of time limits for level 3 implementation and scope of actions.

Action Category	Time Limit*	Minimum Scope	Maximum Scope
Population augmentation	Immediate	Current avg. stocking rate	Variable over time
IRC habitat development	2 years	260K ac-d/yr	Add 500k ac-day/yr
Spawning habitat	2 years*	3 spawning sites	See decision tree**
Spawning cue flows	9 years	Max. implementation scope assumed to be 1 in 3 years for impacts analysis within MP; minimum and maximum required implementation scope will be developed and informed by population models and impact assessments***	

* Anticipated as Level 2 pilot projects focused on developing and evaluating high-quality spawning habitat.

** Spawning habitat implementation will be guided by the decision tree and associated decision criteria as described in the section below on spawning habitat.

*** Pallid population modeling will be used to set minimum spawning flow needs; bird impacts and status may inform decisions regarding spawning cue flows below Gavins Point Dam in any particular year.

Because of the uncertainty regarding the hypotheses and the effectiveness of proposed management actions in increasing pallid sturgeon recruitment, the targets are based on the best information currently available for that particular management hypothesis. As knowledge is gained from level 1, 2 and 3 actions, the timeframe for implementation may be adjusted, targets may be changed, management actions may be refined, and hypotheses may be dismissed. The “rules” by which these decisions will be made are outlined in the decision criteria for the respective management hypotheses, subject to the overarching MRRP governance and decision process laid out in the AM Plan.

Population Augmentation

Action Description: Population augmentation (stocking) of pallid sturgeon is already taking place at a level having a measurable effect on the population (i.e. level 3), and will continue under the Framework. While population augmentation is *necessary* for recovery of the pallid sturgeon, by itself it is not *sufficient* as the Endangered Species Act requires a self-sustaining population. Augmentation can help severely depleted populations recover numbers of individuals needed to evaluate what works and what doesn’t in recovering the population. Additionally, some concurrent level 1 and level 2 components are proposed to develop information to improve on the level 3 implementation (see Figure 1 for an approximate schedule).

Propagation	2016	2017	2018	2019	2020	2021	2022	2023	2024	2025	2026	2027	2028	2029	2030	2031	2032

Level 3																	
Stocking																	

Figure 1. Preliminary schedule of actions related to propagation.

This action will be closely coordinated with the new Pallid Sturgeon Propagation Plan being developed by the Pallid Recovery Team (Wyatt Doyle is the Lead) because of important concerns related to fish health/disease, genetics, stocking size, stocking practices, etc. Once the Propagation Plan is developed, the target values in Table 4 will be adjusted to reflect the role of the MRRP in meeting plan objectives. The target values in the table may best be represented by running averages In addition to or rather than annual minimums or maximums. It is important that the Propagation Plan rely upon the population model being developed as part of the Effects Analysis and Adaptive Management Plan (and in support of the recovery plan) and not other, competing models. The rationale for these decisions will be further articulated in Chapter 4 of the AM Plan.

Objectives: The stocking rate and target number of fish stocked is intended to ensure a 95% probability of persistence for the species over a 50-year period. Short-term objectives are to increase the number of adult pallid sturgeon in the lower Missouri River. Long-term objectives are to reduce and eventually eliminate the need for supplemental stocking by demonstrated wild recruitment at a level sufficient to meet the fundamental objectives. In addition to the above primary objectives, more specific, means objectives for propagation have been identified and include increased fitness and genetic diversity of

released fish, improved brood stock collection, and adjusting hatchery capacity. Some of these efforts are being addressed through Level 1 and 2 studies.

Metrics: The metric for reporting and assessing stocking rates will be yearling equivalents; performance measures will be based on a three-year running average of annual yearling equivalents. Number and survival rates for stocked pallid sturgeon by stocked size, hatchery of origin, and condition; Catch rates of adult pallid sturgeon, along with other measures of fitness or genetic makeup might be employed as supplemental metrics for the primary objective, and metrics for the more specific objective listed above will be identified in the Propagation Plan. *(Note: this is subject to adjustment upon coordination with the Recovery Team on the new Propagation Plan)*

Decision Criteria: Adjustments to the number of fish and their age structure will be based on the results of population modeling and sensitivity analyses using the most up-to-date version of the model available each year. Until the model is sufficiently robust to meet this need, a target of 5000 adult pallid sturgeon in each management unit will serve to guide stocking rates. *(Notes: 1. This is subject to adjustment upon coordination with the Recovery Team on the new Propagation Plan. 2. Criteria for more specific objectives listed above will be presented in the Propagation Plan).*

Triggers for Moving to Higher Implementation Level: No clear transition from level 3 to level 4 exists; implementation at level 3 will continue until such time as supplemental stocking is no longer required.

Trigger for abandoning population augmentation actions: Population augmentation may be halted when population monitoring demonstrates that a self-sustaining population in excess of 5000 fish exists in each management unit, when the threat of extirpation is less than 5 percent in 50 years, or as based on new criteria introduced through the Propagation Plan.

Triggers for adjusting augmentation practices to optimize fitness or genetic diversity: TBD

Timeframe: No specific timeframe for transition is identified. Implementation at level 3 is to begin immediately (i.e. continue from present) following issuance of the ROD.

Level 3 Contingent Actions: Contingency plans for artificial propagation are limited to those associated with the secondary objectives; adjustments to the propagation program will focus on achieving the necessary fitness and genetic diversity.

Monitoring Requirements: See Appendix D of AM Plan

Interception and Rearing Complexes (IRCs)

Action Description: Interception and rearing complexes (IRCs) are areas that meet the functional definitions laid out in the Effects Analysis Integrative Report. For the purpose of establishing targets and measuring progress, the physical definitions of IRCs are currently identified as follows: 1) food-producing

habitat occurs where velocity is less than 0.08 m/s, 2) foraging habitat is defined as areas with 0.5 – 0.7 m/s velocity and 1-3 m depth, and 3) interception habitat has been qualitatively described as zones of the river where hydraulic conditions allow free embryos to exit the channel thalweg. A functional IRC exists where the juxtaposition of the described habitats is such that all three functions are performed and collectively contribute to survival to age-0. The above requirements will be adjusted as needed based on new knowledge regarding the suitability of conditions for IRC habitat.

The availability of food-producing and foraging habitats varies with flow, as does the local hydraulic field at any location (and hence the potential for interception and retention). Consequently, IRC habitat is flow-dependent and time-variant and can be affected by both mechanical manipulations of river geometry and flow management actions. For the timeframe addressed by this EIS (approximately 15 years), flow management will not be required to meet any IRC targets associated with Level 3 unless information developed during Level 1 and Level 2 implementation unequivocally demonstrates the need for flow manipulation. Because flow manipulations will not be assessed under the current actions for Level 3, additional NEPA analysis of those actions would be required before any implementation efforts are undertaken.

Level 1 and 2 activities associated with IRCs focus on 1) the need for additional IRC habitat, 2) refining the relationship between the habitat components, flow (utilizing current operations), and the biological requirements of each habitat type, 3) the needed habitat characteristics and their spatial and temporal distributions, and 4) determining the effectiveness of various mechanical activities and the potential for flow management actions to contribute to future IRC needs. A proposed sequencing for actions associated with IRCs is shown in Figure 2. To the extent possible and where appropriate, Level 1 and 2 activities will incorporate habitat projects which have already been completed. Although the habitat focus has changed from SWH, there is likely much that can be learned from existing SWH projects.

Level 3 actions include physical manipulation of habitats and structures on the Missouri River to create or improve areas having hydraulic conditions to intercept drifting free embryos combined with food-producing habitats and foraging habitats. Actions might be directed at one or any combination of the three components of IRCs. Examples include adjustments to navigation training or bank stabilization structures, channel widening, floodplain modifications or other adjustments to channel geometry, placement of structures to encourage development of needed habitat or habitat complexity, chute development or adjustments to existing chutes, etc. In addition to development of functional IRCs, management actions will be aimed at ensuring availability of IRC habitats over a wide range of flows as well as the necessary spatial characteristics (distribution, concentration, proportions, etc.,) on the lower Missouri River such that interception, food production, and foraging are not preventing the achievement of the pallid sturgeon fundamental objectives.

Creation of IRC																	

Figure 2. Preliminary timeline for IRC action Implementation.

The targeted longitudinal distribution of IRCs will be influenced by biological needs as outlined in the EA and supported by results of larval drift modeling as well as other practical considerations. It is anticipated that IRCs will be concentrated downstream from RM 595 but, due to uncertainty regarding drift behavior and potential benefits of temporal retention, IRCs will not be restricted to areas below RM 595, and the strategy for site selection will be based on maximizing knowledge. Projects with potential to quickly reduce uncertainties will be emphasized to the extent practicable. New IRC habitat resulting from both level 2 and level 3 actions that meets the IRC criteria will be counted as contributing to the targets for level 3 (i.e. credit is based on measured project outcomes). Level 3 actions and outcomes are focused on helping understand and describe what level 4 actions and targets will be.

Long-term (Level 4) targets will be based on bioenergetics requirements of the Missouri River pallid sturgeon population. Lacking the ability to reliably establish those needs at present, Level 3 targets for IRC are to be based on the rate the Corps has demonstrated that they can create shallow water habitat (SWH). The SWH historical implementation rate (acres/year) will be converted into a flow-variant metric for IRCs (in acre-days per year) that accounts for food-producing and foraging habitat availability in proximity to areas of effective interception and retention of larval pallid sturgeon. The result of this transformation will be to characterize (as a range, an average over some reasonable timeframe, or both) the expected amount of “lift” in availability of IRC habitat during the (temperature dependent) growth period for pallid sturgeon. Growth period for larval and juvenile pallid sturgeon occurs from May through October. Because of early life history transition to first feeding the month of June will be the highest priority with a focus on learning and refining our understanding of the relationship between temperature, flow and river geometry. We will continue to look into the best way to categorize time frame to assess this relationship.

Associated Hypotheses: 1). Interception habitat - Improved or increased interception of drifting free embryos from the thalweg and transport to supportive channel-margin habitats will increase survival of free embryos to exogenously feeding age-0. 2). Food production habitat - A lack of food limits survival of age-0 pallid sturgeon. 3). Foraging habitat - An increase in availability and quality of foraging habitat will increase survival of age-0 pallid sturgeon.

Objectives: Primary - Ensure that interception of drifting free embryos, food production and effective foraging for age-0 pallid sturgeon do not seriously limit recruitment in the lower Missouri River, either locally or systemically; Secondary - 1) progress toward the Targeted amount and distribution of IRC

habitat, and 2) number of specific means objectives will be established as appropriate to promote the optimization of IRC development and to protect HC interests.

Metrics: The means objectives by which the Corps will be evaluated in meeting their obligations under the BiOp are based on the net increase in “effective” acreage of IRC habitat (in acre-days/yr) listed in Table 4. “Effective” acreage is determined by integrating the developed or available IRC habitat with mean daily flows for June through September, expressed as acre-days. These dates correspond with the period of growth for pallid sturgeon ($T > 13^{\circ} \text{C}$). IRC habitat occurs where foraging habitat is collocated with or proximal to and downstream of food-producing habitat, and is intersected with hydraulic conditions in June that would promote interception and retention of free embryos drifting in the channel. Habitat metrics will be based on measures of depths, velocities, and substrate, including central tendency and variance, potentially complemented with metrics of spatial complexity. Figure 3 below is an example of how IRC habitat is counted. The algorithm for calculating IRC habitat might weight the hydrograph in June higher because of the importance of first feeding to survival. Distribution will be evaluated as deviation from a target distribution.

(need Figure) [Figure was not submitted with the planning aid letter.]

Figure 3. Example of IRC habitat accounting.

Performance of IRC actions will also be based on a subset of metrics addressing the primary objectives outlined above. The effectiveness of projects in promoting interception will be based on CPUE of age-0 sturgeon at project (pre- and post-implementation) and reference sites in the months of June through September. Effectiveness in terms of food production will be based on production of food per unit area, survival and indicators of starvation or impending death of age-0 pallid sturgeon (percentages of

empty/full stomachs; lipid content). Effectiveness in terms of foraging will be based on gut content and survival of age-0 pallid sturgeon with consideration for bioenergetics requirements of age-0 pallid sturgeon. Survival rates of hatchery-reared first-feeding pallid sturgeon larvae released in the Missouri River may serve as a metric for all three IRC elements.

A suite of metrics for assessing the hypotheses underpinning IRCs and the associated Level 1 and 2 studies are presented in the AM Plan.

Decision Criteria: The targets for implementation rate afford a straight-forward measure of compliance with the means objectives for IRCs at level 3. Net increases in habitat will be computed on an annual basis. To permit flexibility to address needs while promoting learning through level 2 actions and to address programmatic requirements related to piping plovers, performance relative to targets will be assessed using a running average of annual lift in IRC habitat. Acceptable performance is meeting or exceeding targets based on a three-year running average for at least 4 of every 5 years (80% success rate).

A host of additional decision criteria are expected in association with specific management actions and level 1 or 2 studies. These will be summarized in the AM Plan. Assessment of overall performance of many actions with statistical relations will likely not be robust, and decisions will therefore require a judgement based on lines of evidence. If experimental results in level 2 studies fail to support systematic increase in habitat and fish condition, then the hypothesis may need to be refined or abandoned. If the experimental results support the hypothesis that channel reconfigurations can provide increased food-producing and foraging functional habitats, and increase pallid sturgeon condition, then the decision would be to move toward level 3 implementation.

Triggers for Moving to Higher Implementation Level: The decision to move from level 3 to full implementation at level 4 will be based on a systematic relation between IRCs and increases in growth and survival of age-0 sturgeon that permits modeling of the needed scope of IRC implementation to meet the fundamental objectives. This judgement should be based on the strength and replicability of relations between abiotic habitat variables describing food and forage habitats, and growth and survival of age-0 sturgeon. In addition, the need for supplemental flow management at level 3 or 4 would be based on the availability of sound relations between flow conditions, IRC habitat, and growth and survival of age-0 sturgeon.

Timeframes: Implementation of IRC habitat at level 3 will occur no later than two years post-ROD. No time limit for transition to level 4.

Level 3 Contingent Actions: Contingency plans for IRCs are mainly associated with the secondary objectives (e.g. structure manipulations will not adversely affect navigation); however, adjustments to the targets, habitat criteria, methods, etc. might be required if performance fails to meet expectations. Details of contingency plans will be presented in the AM Plan.

Monitoring Requirements: See Appendix D of AM Plan

Spawning Habitat

Hypothesis: The spawning habitat hypothesis is highly uncertain with multiple hypotheses influencing potential directions and action. The hypothesis with the highest potential to provide rapid learning and insight is that high quality spawning habitat is limiting. Pilot projects (at Level 2) to address this hypothesis can be implemented within a few years and could greatly improve our understanding of the relationship between spawning habitat and successful reproduction. The decision tree below shows the strategy for moving forward on this hypothesis and potentially it's alternate.

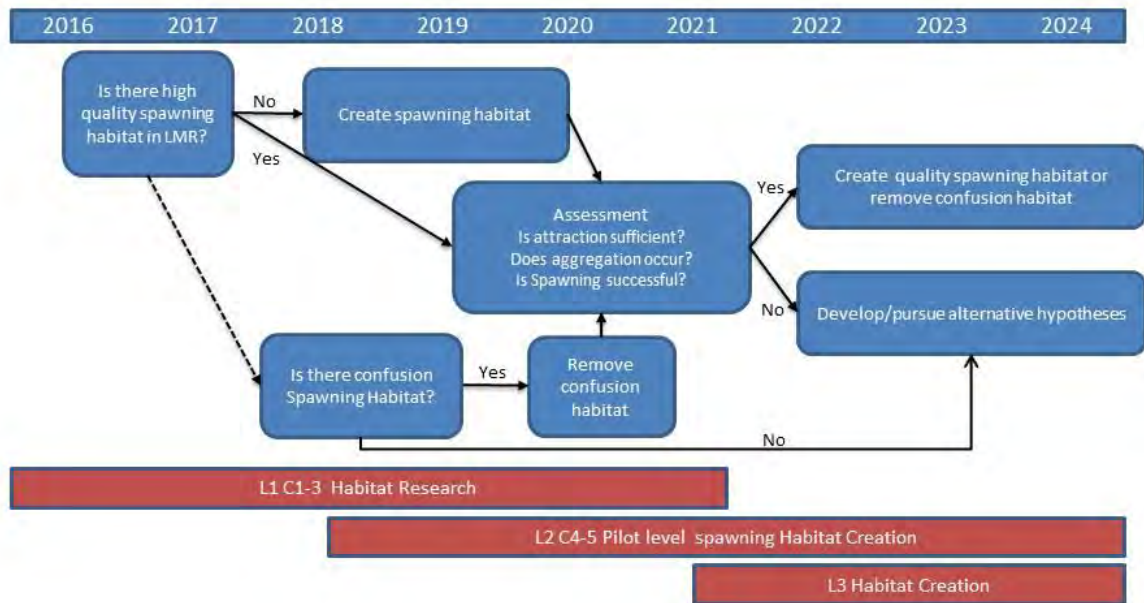

Figure 4. Decision tree for spawning habitat.

Description and Objectives: We presently do not have sufficient understanding to characterize the necessary actions at level 3 or determine quantifiable targets for spawning habitat. The focus of Level 1 and 2 will be to reduce the uncertainty regarding spawning habitat characteristics and needs for successful recruitment. There are two competing high-level hypotheses regarding spawning habitat concerns; one hypothesis is that additional high-quality spawning habitat is needed, while the opposing hypothesis is that too much poor-quality (i.e. “confusion”) spawning habitat exists on the river. Because the first hypothesis is much easier to test, the AM strategy will focus on that hypothesis first and pursue the confusion habitat hypothesis only if Level 1 or 2 studies reject the first hypothesis or provide added support to the second. A decision tree has been developed to guide the development of decision criteria related to the spawning habitat activities at levels 1 through 3.

An early emphasis will be to utilize information from the Yellowstone River to inform Level 2 pilot projects on the Lower Missouri River, which will be monitored for effectiveness based on metrics

ranging from observed aggregation to the number of free embryos in the water column. Level 3 targets for spawning habitat may be beyond the 15 year timeline under the planning process, depending on the rate of learning from Level 2 activities. However, the amount of habitat required to support successful spawning, the relative costs and ease of construction, and the anticipated low level of impacts to other uses suggests that even arbitrary and conservative targets for spawning likely won't have a big impact when associated with the first hypothesis. In contrast, should the confusion hypothesis bear out, the impacts and costs are likely to be substantial.

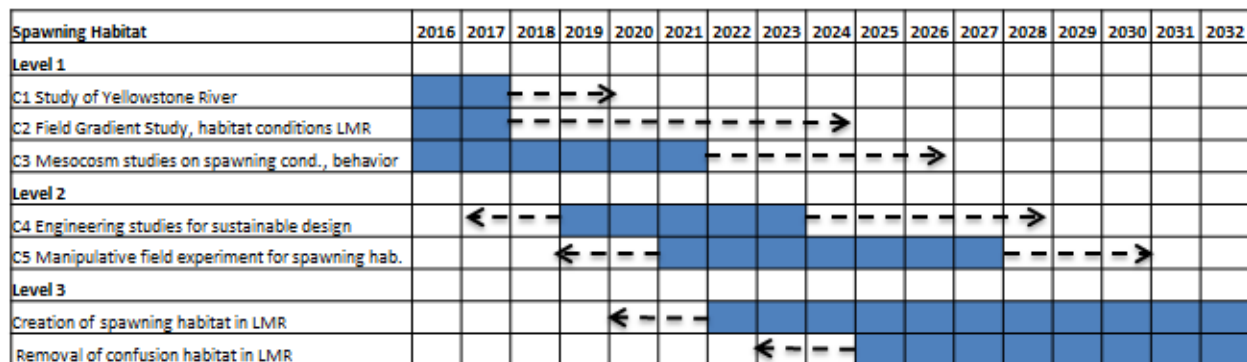

Figure 5. Preliminary sequencing of actions and studies for spawning habitat.

Metrics: The ultimate metric for spawning habitat is hatch rate as a function of habitat availability. Habitat might be characterized using different combinations of depth, velocity, substrate, and derivative hydraulic variables, with covariates relating to water quality and fish behaviors. Intermediate metrics will be fundamental measures of fish aggregation and spawning behaviors (for example, optimum male: female ratios in spawning aggregations), degree of attraction/specificity of adults to different spawning substrates, and biomechanics of egg adhesion and dispersal.

Several other metrics will provide information on relative performance of different designs. Repeat high-resolution multibeam maps of the spawning patches during incubation will indicate whether the substrate is subject to burial or erosion, which is likely to result in zero hatch. Measured hydraulic variables can be compared to fall velocities of unfertilized eggs to evaluate whether eggs are likely to be deposited in the manipulated habitats; multi-receiver, 3D telemetry and acoustic video can be used to evaluate behaviors of reproductive adults on the spawning patches to identify spawning aggregations and egg-release events.

Decision Criteria: The relevant decision for the level 2 studies associated with the first hypothesis would be whether to move forward into full implementation, change the experimental patch design, or abandon the habitat quality hypothesis and pursue the confusion habitat hypothesis. Robust statistical results cannot be expected for the preferred metric (hatch rate) because of the difficulties in enumerating this under field conditions. However, the results of other metrics described above should contribute to a lines-of-evidence decision of whether the spawning patches are functioning as intended.

Criteria for Accepting or Rejecting Hypotheses: Lines of evidence.

Triggers for Moving to Higher Implementation Level: (list time, performance, or other criteria for moving from L1 to L2, L2 to L3 and from L3 to L4) Evidence based criteria: Fish use of created habitats in multiple years; larval fish below spawning sites; increased catches of 2-3 year old pallid.

Timelines: No specific timeline for these hypotheses has been established, though the timelines in the above figures provide a sense of the expected outlay of effort and the sequencing/dependencies of certain activities.

Level 3 Contingent Actions: Information provided through field experimentation will indicate whether channel geometries and/or substrate should be altered to improve performance of spawning patches, and whether additional locations would contribute to spawning success and population growth. Rejection of the “quality habitat” hypothesis would result in pursuit of the alternative “confusion habitat” hypothesis, though the daunting nature of that undertaking has prevented an outlay of the necessary actions to date.

Monitoring Requirements: See Appendix D of AM Plan

Spawning Cue Flows

Hypothesis: Spring flow pulses from Gavins Point will provide aggregation and spawning cues.

Action Description: A description of a spring pulse sufficient to define a level 3 implementation is presented below. The frequency highlighted in Table 4 is uncertain due to insufficient understanding of the requirements for pallid sturgeon and potential effects of frequency on tern and plover nesting success. Further sensitivity analyses will be conducted with both population models to provide greater understanding of the bounds of this action through evaluation of the effects of releases on the bird and fish population trends and the pallid sturgeon population model will be used to guide the ultimate frequency of pulse implementation. A suggested maximum frequency of 1 in 3 years was agreed upon as an estimate for the purposes of assessing effects on stakeholders.

Level 3 spawning cues consist of deliberate bi-model pulse flows from Gavins Point dam as described below. The flows would be implemented at a frequency sufficient to elicit successful spawning in at least 1 of 3 years, or as dictated by the results of the population model (*<needs further characterization>*). Options for increasing the variability in the overall pulse height should be explored to more closely mimic the variability that occurred naturally as a means of precluding impacts on sandbar nesting birds.

The first pulse from Gavins Point would conform to the following guidelines:

- Rise begins on first day after flow to target navigation flows are achieved.
- Peak release from Gavins Point is equal to double the flow to target level release the first day of navigation flow to target levels are achieved from Gavins Point
- Increase to peak by 2,200 cfs per day
- Maintain peak for 2 days

- Reduce pulse by 1,700 cfs/day until releases are back to base flow to target levels

The second pulse is cued by water temperature (**16-18 degrees**) at a particular point as follows.

- Checks to implement release increases
 - > 40.0 MAF in System Storage on March 15 storage check
 - Steady release has been set and implemented for 3 days
- Releases from Gavins Point
 - Rise begins on May 18 or later based upon water temperature and implementation of steady release for at least 3 days
 - Increase to peak by 2,200 cfs per day
 - Peak release from Gavins Point is equal to twice the steady release from Gavins Point
 - Maintain peak for 2 days
 - Reduce pulse by 1,900 cfs per day until the steady release flows are reached
- Flood targets will be the full service flood targets increased by the steady release level
 - If the steady release is 31 kcfs and the full service flood targets are 41 kcfs, 47 kcfs, and 71 kcfs at Omaha, Nebraska City, and Kansas City, respectively, the new flood targets will be 72 kcfs at Omaha (31 + 41), 78 kcfs at Nebraska City (31 + 47), and 102 kcfs at Kansas City (31 + 71).

Spawning flows																	

Figure 6. Preliminary sequencing of actions and studies for spawning flow cues.

Objectives: Spawning cue flows are intended to 1) elicit a movement response in gravid pallid sturgeon that 2) results in an aggregation of reproductively ready pallid sturgeon

Metrics: Success metrics for spawning cues are generally related to fish behavior (reproductive migrations and successful spawning with monitored experimental flow pulses) and successful reproduction (hatch rate, capture of free embryos, etc.). Practical assessment of spawning success in the near-term is extremely difficult, so the need to rely upon behavioral monitoring is likely. Intensive telemetry tracking data of reproductive adults (males and females) will be evaluated against time series of hydrologic characteristics and will be analyzed for degree of association. Reproductive success or failure could be inferred by recapturing reproductive fish soon after expected spawning events to determine if they have released gametes. Monitoring of a series of pulsed flow releases over several years may be required to establish a functional relationship between flow-pulses and probability of producing viable larvae.

Decision Criteria: The significant experimental control that could be exerted over this action (for the upper river) will add to the ability to detect and quantify reproductive behavioral changes related to flow pulses; however, the flow pulses will still take place within a system where many sources of variability are not controlled, such as weather systems and tributary inputs. It is therefore unlikely that these experiments will result in a statistically rigorous result. Instead, a decision to accept the value of manipulated flow pulses in increasing pallid sturgeon reproductive success, or to reject it, will probably be based on judgement of multiple lines of evidence.

Timelines: The time to implementation at Level 3 and sequencing of this action should be considered in light of other actions, i.e., before we run a flow pulse, availability of spawning habitat with reasonable expectation of functionality and a sufficient number of fish in the system to assess aggregation should be assured. This could mean that additional engineered spawning habitat be in place (see previous section), but presently available spawning sites may suffice to address behavioral metrics. A nine-year time limit for Level 3 implementation was agreed upon to allow for habitat and propagation efforts to enhance the potential success of spawning cue flows. Information derived from Level 1 or 2 studies and/or passive monitoring of natural flow events could move the time frame up or could result in a rejection of the hypothesis. At nine years we would expect a minimum of two implemented pulses to have occurred within the temporal scope of the current EIS. This would allow for future NEPA analysis to better discern how and/or if pulses should be subsequently implemented.

Triggers for Moving to Levels 3 or 4: TBD

Level 3 Contingent Actions: TBD

RE: Planning Aid Letter Regarding Task B1 in the Missouri River Recovery Program FWCA
Scope or Work – FY 2015

Dear Ms. Fitzner:

The U.S. Fish and Wildlife Service (Service) provides this planning aid letter (PAL) to assist in the development of the U.S. Army Corps of Engineers' (Corps) Missouri River Recovery Management Plan / Environmental Impact Statement (MRRMP-EIS) in accordance with the Fiscal Year 2015 Fish and Wildlife Coordination Act (FWCA) scope of work agreed to by our agencies. This letter fulfills Task B1 contained in the FY-2015 scope of work. As a cooperating agency on the MRRMP-EIS, the Service provides the following comments pursuant to the FWCA of 1958, as amended (48 Stat. 401; 16 U.S.C. 661 et seq.), the NEPA of 1969 (42 U.S.C. 4321-4347), and the Endangered Species Act (ESA) of 1973, as amended (87 Stat. 884; 16 U.S.C. 1531 et seq.).

This PAL does not constitute the final report of the Secretary of the Interior as required by Section 2 (b) of the FWCA for the MRRMP-EIS, nor does it constitute reconsultation of the 2000 and 2003 Amended Biological Opinion on the Operation of the Missouri River Main Stem Reservoir System, Operation and Maintenance of the Missouri River Bank Stabilization and Navigation Project (BSNP), and Operation of the Kansas River Reservoir System (BiOp) under section 7 of the ESA.

The purpose of the MRRMP-EIS is to develop a suite of actions to meet ESA responsibilities for the threatened Northern Great Plains (NGP) population of the piping plover (*Charadrius melodus*), the endangered interior least tern (*Sternula antillarum*) (ILT) and the pallid sturgeon (*Scaphirhynchus albus*); and the authorized purposes of the operations of the dams using Corps authorities. The geographic scope of the MRRMP-EIS encompasses the main stem portions of the Missouri River from Fort Peck, Montana to St. Louis, Missouri. The EIS will assess the

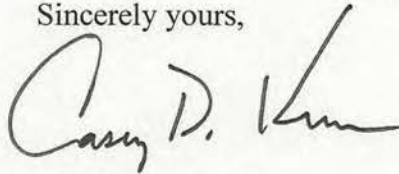

current Corps programmatic impacts, cumulative effects and a range of potential alternatives. The MRRMP-EIS will include an adaptive management process for all Missouri River Recovery Program (MRRP) activities to ensure management decisions and actions are continuously improved by the learning that takes place from research and regular monitoring of the river.

To support the development of the MRRMP-EIS, Service staff assisted with the effects analysis of the piping plover and least terns, pallid sturgeon, and habitat (hydraulics and hydrology) of the Missouri River. Three working groups, lead by Dr. Kate Buenau (Pacific Northwest National Laboratory), Dr. J. Craig Fischenich (U.S. Army Engineer Research and Development Center (ERDC)), and Dr. Robert B. Jacobson (U.S. Geological Survey), produced the Draft Interim Effects Analysis Integrated Reports.

The Service hereby acknowledges the receipt of these three reports and fully supports their results and use in completion of the MRRMP-EIS for the Missouri River Recovery Program.

We look forward to our continuing collaboration with the Corps and other conservation partners in support of this important effort to ensure the success and ultimate implementation of the MRRMP-EIS for the recovery of the fish and wildlife resources of the Missouri River, while also taking into consideration the human resources. If you have any questions, please feel free to contact me at (605) 665-4856.

Sincerely yours,

RE: Planning Aid Letter Regarding the Missouri River Recovery Management Plan-EIS:
USFWS 2003 BiOp Projected Actions Alternative

Dear Ms. Fitzner:

The U.S. Fish and Wildlife Service (Service) provides this planning aid letter (PAL) regarding the development of the U.S. Army Corps of Engineers' (Corps) Missouri River Recovery Management Plan Environmental Impact Statement (MRRMP-EIS) in accordance with the Fiscal Year 2015 Fish and Wildlife Coordination Act (FWCA) scope of work agreed to by our agencies. The Service provides the following comments pursuant to the FWCA of 1958, as amended (48 Stat. 401; 16 U.S.C. 661 et seq.), the NEPA of 1969 (42 U.S.C. 4321-4347), and the Endangered Species Act (ESA) of 1973, as amended (87 Stat. 884; 16 U.S.C. 1531 et seq.).

This letter transmits parameters for modeling the USFWS 2003 Biological Opinion (BiOp) Projected Actions Alternative for the MRRMPP-EIS as part of the alternative development process and should not be construed as Section 7 input. We appreciate the dialogue that has occurred between the Corps PDT and Service staff to date on this effort. We especially appreciate the efforts of the Corps modeling team of Jeff Tripe, Don Meier, Dan Pridal, Jean Reed, Christine Cieslik, Ryan Larsen, Alex Flanigan and others who worked patiently and professionally through the modeling parameters with our staff. Please include the USFWS 2003 BiOp Projected Actions Alternative within the MRRMP-EIS.

The USFWS 2003 BiOp Projected Actions Alternative provides our interpretation of the ultimate implementation of the BiOp RPA. Whereas the No-Action alternative projects only current actions being implemented long term, the USFWS 2003 BiOp Projected Actions Alternative includes projections of additional iterative actions and expected actions which the Service anticipated would ultimately be implemented as part of the BiOp Reasonable and Prudent Alternative (RPA) through adaptive management and as impediments to implementation were removed. The Service recognizes that all of the actions listed and included for modeling from the 2003 BiOp would not have been implemented immediately. Nevertheless, we believe it is

important to understand the projections, consequences and benefits from the ultimate implementation of the 2003 BiOp through complete analysis of the USFWS 2003 BiOp Projected Actions Alternative. We believe including the USFWS 2003 BiOp Projected Actions Alternative provides a necessary portion of a complete range of alternatives. Moreover, it is a necessary component for the Service to assess the difference and benefits of any of the other alternatives in terms of the efficacy in achieving objectives for the pallid sturgeon, interior least tern and piping plover.

Modeling parameters and documentation of rationale follow and are separated into three components: Flows, Shallow Water & Floodplain Habitat, and Emergent Sandbar Habitat. Specific relationships of BiOp actions to species needs/actions are included to enable direct comparison of the USFWS 2003 BiOp Projected Actions Alternative with other MRRMP-EIS alternatives.

FLOWS:

The Service provides these relationships to facilitate comparison with other alternatives. The flow parameters are associated with the lower Missouri River pallid sturgeon, the interior least tern and the piping plover specifically as follows:

- Least terns and piping plovers – Reservoir Unbalancing
- Pallid Spawning Cue – First and Second Pulse
- Spring ESH Creation – First and Second Pulse
- IRC Habitat – First and Second Pulse & Summer Low Flows
- Low Nesting Season Flows – Summer Low Flows

FLOW PARAMETERS

- Reservoir unbalancing as described in the master manual
- If “no service” is determined on March 15, GAPT releases are to be determined based on meeting water supply targets until the winter season; first and second pulses will not be carried out.
- Max winter GAPT release: 16 kcfs
- First Spring Pulse from GAPT
 - Start about March 15 to coincide with normal come-up for navigation
 - Rise to 31 kcfs
 - 7 day ascending limb
 - 7 days at peak (31 kcfs)
 - 7 day descending limb
 - Disregard pulse if storage evacuation service level is determined by March 15 assessment
- Following first spring pulse, return to flow to target (FTT) operations based on service level from March 15 storage check
- Second pulse to initiate between May 1 and May 15
 - Ascending limb not less than 7 days, but no longer than 10

- Descending limb not less than 7 days
- Pulse rise based on March 1 runoff forecast
 - Median = 16 kcfs
 - Upper quartile or higher runoff = 20 kcfs rise
 - Lower quartile or lower runoff = 12 kcfs rise
- Pulse duration at peak
 - 14 days – lower quartile or lower runoff
 - 25 days – median runoff
 - 35 days – upper quartile or higher runoff
- Flood control constraints
 - Add pulse magnitude to the current USACE flood control constraints outlined in Tables VII-7 and VII-8 in master manual
 - Limit max pulse release from GAPT to 60 kcfs.
- End of second pulse to June 23: return to “steady release” scenario to specify GAPT releases
 - Use June release value from the Annual Operating Plan “Gavins Point releases Needed to Meet Target Flows”
 - Median, Upper Q, Upper D: 27.9 kcfs full service, 21.9 kcfs min service
 - Lower Q, Lower D: 31.2 kcfs full service, 25.2 kcfs min service
- Summer Low Flows
 - If steady releases are lower than 25 kcfs – stay on the steady release level until the summer low flow reduction to 21 kcfs.

June 23rd to July 1

- 25 kcfs GAPT release
- July 1: Assess navigation season length
 - If there is a shortened navigation season as determined by the Master Manual
 - GAPT releases are to be determined based on meeting water supply targets (open channel non-navigation season)
 - The duration of those releases is equivalent to that of the number of days the season is shortened less the 8 days in June (eg. if season is shortened 30 days,
 - Following that duration, set flow to 25 kcfs until July 15 then drop the release to 21 kcfs until August 15 and then return to 25 kcfs until Sept 1
 - FTT operations from Sept 1 until Dec. 1
 - If there is not a shortened navigation season
 - Continue 25 kcfs from July 1-July 15 then drop the release to 21 kcfs until August 15 and then return to 25 kcfs until Sept 1
 - Flow to target operations from Sept 1 until Dec. 1 or Dec 10 if a ten day extension is determined

Frequency of the bimodal pulse and summer low flows

- An attempt should be made to run the bimodal pulse every year. The Service recognizes that the full bimodal pulse will only be realized about once in every eight years based upon preliminary modeling results and discussions with USACE staff.
- Summer low flows should only be implemented in years when the full bimodal pulse occurs.

The flow parameters are primarily outlined in RPA VII of the 2003 Amended BiOP.

Variations of the technical criteria within RPA VII are founded in the following statements resulting in a shift from those criteria and ultimately projecting implementation of an Adaptive Management Program as defined in RPA I.

"The long-term flow regime shall be reflective of the normalized river hydrology in order to be responsive to dry, intermediate, and wet conditions." p. 234 of the 2003 Amended BiOP

We have included the following excerpt to clarify why the USFWS 2003 Biological Opinion Projected Actions Alternative includes low summer flows:

"the Corps shall ensure that the Master Manual and the corresponding NEPA document provide the latitude for the eventual implementation of a spring rise and summer low flow of at least a magnitude identified in the Draft Environmental Impact Statement (USACE, 2001) as alternative GP2021." p. 233 of the 2003 Amended BiOP

SHALLOW WATER HABITAT and FLOODPLAIN HABITAT

Shallow Water Habitat and Floodplain Habitat are both associated with lower Missouri River pallid sturgeon.

The Service provides this relationship to facilitate comparison with other alternatives. Shallow water and floodplain habitat are associated with the lower Missouri River pallid sturgeon as follows:

- IRC Habitat – Shallow water habitat and Floodplain habitat

Key references to the suite of parameters include the following:

Pallid Sturgeon RPA

III. Habitat Restoration/Creation/Acquisition

"Continued survival of pallid sturgeon depends on restoration of riverine form and functions, as well as some semblance of the pre-development or natural hydrograph.

Missouri River habitat restoration is, therefore, multi-faceted, and involves a combination of reservoir operational changes (e.g., hydrograph and temperature), structural modifications (e.g., chute restoration), and non-structural actions (e.g., floodplain acquisition or easements). The maximum benefits of physical habitat projects to listed species can only be realized when coupled with complementary hydrology.” p. 226 of the 2003 Amended BiOP

VI. Feasibility, Flow Development, and Adaptive Management

“determine impediments to implementing the flows necessary to ensure the survival of pallid sturgeon, and identify mitigation measures to address the impacts of removing impediments to implementation (e.g. floodplain easements, scouring easements, navigation off-sets).” p. 231 of the 2003 Amended BiOP

VII. Flow Modification

“flows that provide for connection of low-lying lands adjacent to the channel. Inundation of low-lying lands is important processes for pallid sturgeon survival. This provides organic material and redistribution to produce forage for rearing fish at a time synchronized with the presence of larval and juvenile fish. Flows that are sufficiently low to provide for shallow water habitat as rearing refugia and foraging areas for larval, juvenile, and adult pallid sturgeon are also necessary.” p. 232-233 of the 2003 Amended BiOP

“This long-term flow regime must address, based on the best available information, spawning, rearing, maximization of floodplain connectivity, forage production and shallow water habitat.” p. 234 of the 2003 Amended BiOP

“By providing flows that are sufficiently high in the spring, connectivity to low-lying lands will be enhanced thereby providing additional production and input of nutrients and forage items for YOY fish at a time needed to enhance survival through the first year. Habitat flows will subsequently provide low velocity refugia habitat, enhanced in-channel productivity and provide for the spatial and temporal concentration of forage and prey items to areas where YOY and adult fish can exploit the prey base.” p. 235 of the 2003 Amended BiOP

IX. Habitat Development, Shallow Water and Floodplain

“Floodplain inundation and connectivity is essential in order to maximize the production of the forage base for pallid sturgeon. The forage base production must occur at a time that coincides with larval sturgeon becoming active, free swimming feeders. Floodplains

are highly productive habitats in the late spring and early summer when warm, shallow water floods over the area and produces a bloom of forage that is of the appropriate size for larval fish to eat. Since larval and juvenile pallid sturgeon feed along the river margins, the productivity must be transported from the inundated low-lying lands to the river as flows recede. Additionally, low-lying are an extremely important source for other floodplain spawning fish which subsequently support the forage base for adult pallid sturgeon through the summer and fall. Highly productive floodplains are necessary on a frequent annual basis to provide necessary life requisites for pallid sturgeon survival." p. 237 of the 2003 Amended BiOP

"Shallow water and floodplain habitat... maximize habitat potential under the range of flows that will be provided under the flow enhancement components of this opinion...shallow water habitat elements should consider, and be implemented with, a flexible and diverse flow regime in mind." p. 237 of the 2003 Amended BiOP

"The Corps shall design and implement floodplain connectivity to produce the intended ecological functions for production of nutrients and forage fish and plankton over a range of flow regimes developed under elements VI and VII above." p. 238 of the 2003 Amended BiOP

The 2003 Amended BiOP also considered interrelated and interdependent actions during consultation. It is assumed that these actions would be completed and factors into the Service determination and resultant opinion. It was assumed that 100,000 of the 166,750 acres of the Missouri River Fish and Wildlife Mitigation Project would be utilized for shallow water habitat and available for floodplain connectivity (Mike Thabault, ARD-ES USFWS Region 6, pers. comm.).

INTERRELATED AND INTERDEPENDENT ACTIONS

Least Tern, Piping Plover, and Pallid Sturgeon

Missouri River Fish and Wildlife Mitigation Project

In the Water Resources Development Act of 1999, the Missouri River Fish and Wildlife Mitigation Project (MRFWMP) was reauthorized to include an additional 118,650 acres of land to be purchased from willing sellers on which to develop, restore or enhance fish and wildlife mitigation sites along the Missouri River. The total acres for the program now stand at 166,750." p. 173 of the 2003 Amended BiOP

FLOODPLAIN HABITAT

We provide the following criteria to allow for analysis/comparison/contrasting/modeling of what the 2003 BiOp did say for this process:

1. Maximize floodplain habitat by ensuring that 77,410 acres of connected floodplain are inundated at a 20% annual chance exceedence (ACE) (or 5-yr).
2. Distribute floodplain habitat to the extent possible based on the table below:

State *	Portion of authorized acres available for floodplain connectivity	Existing acres of floodplain connectivity (20% ACE inundation)*	Additional acres of floodplain habitat to add to HEC-RAS model
Iowa	14,228	16,120	0
Kansas	6,976	8,560	0
Missouri	62,813	99,980	0
Nebraska	15,983	31,820	0
Total	100,000**	156,480***	0

*Does not imply ownership, includes both public and private lands.

**The 100,000 inundation acreage includes both the main channel and connected floodplain area.

The 77,410 inundation acreage includes only the connected floodplain area.

***Does not include main channel acres as defined by median August flows.

3. Acres of existing floodplain connectivity were reported by USACE based on HEC-GeoRAS mapping. Upper Mississippi River System Flow Frequency Study (UMRSFFS) 20% ACE flows were run as steady flows in the existing conditions HEC-RAS model, and inundation boundaries were created using the best available terrain data.
4. Existing acres of floodplain inundation with connectivity includes:
 - a. Areas lower in elevation than the computed 20% ACE water surface and judged to be connected to the main channel.
 - b. Private lands not protected by levees, including fringe areas between levees and river bank and areas without any discernable protection that would be inundated at the reference flow.
5. Excluded from existing floodplain acres:
 - a. Area behind all active/maintained levees, including federal levees, levees in the PL 84-99 program and smaller agriculture levees often found between the federal/program levees and the river bank. No distinction was made as to levee reliability or performance risk. All levee areas were excluded from the count of existing acres of floodplain connectivity.
 - b. Inundated area well outside the bluff line or in tributary backwater areas.
 - c. Missouri River main channel as determined by the boundary of the August 50% duration flow extent.

6. Modeling efforts and assessment should strive towards the following (repeated from above RPA IX):
 - a. Floodplain inundation and connectivity is essential in order to maximize the production of the forage base for pallid sturgeon. The forage base production must occur at a time that coincides with larval sturgeon becoming active, free swimming feeders. Floodplains are highly productive habitats in the late spring and early summer when warm, shallow water floods over the area and produces a bloom of forage that is of appropriate size for larval fish to eat. Additionally, low-lying lands are an extremely important source for other floodplain spawning fish which subsequently support the forage base for adult pallid sturgeon. Highly productive floodplains are necessary on a frequent annual basis to provide necessary life requisites for pallid sturgeon survival.

SHALLOW WATER HABITAT PARAMETERS

1. Add shallow water habitat (SWH) to the HEC-RAS models based on the 2003 Amendments to the 2000 Biological Opinion (BiOp) and in accordance with subsequent discussions between the U.S. Army Corps of Engineers and U.S. Fish and Wildlife Service.
2. Future habitat will be modeled, to the extent possible, by selecting locations along the river with reasonable characteristics for habitat construction and that do not interfere with existing human infrastructure.
3. Total SWH to be placed in models downstream of Gavins equals 11,265 acres. This is equal to the amount required by the BiOp to achieve 30 acres/mile (753 miles x 30 ac/mi = 22,590 acres) minus the existing acres of SWH as reported by USACE in the 2014 SWH Accounting Report (11,325 acres).
4. Distribute SWH acreage based on the table below.

Reach	Segment	Required Acres of SWH (30 ac/mi)	Existing Acres of SWH (2014 SWH accounting report)	Additional acres of SWH to add to HEC-RAS model
Ponca to Sioux City	Segment 11	540	120	420
Sioux City to Platte River	Segment 12	4,200	1,682	2,518
Platte River to Kansas River	Segment 13	6,840	2,560	4,280
Kansas River to Osage River	Segment 14	7,110	3,710	3,400
Osage River to Mouth	Segment 15	3,900	3,253	647
Total		22,590	11,325	11,265

* Platte River to Kansas City reach will be pro-rated between the two districts by river length, 57% will be accomplished by NWK and 43% by NWO.

5. SWH will be some combination of in-channel habitat and off-channel habitat. Diversity is important, however, added habitat will favor in-channel widening to the extent possible.
6. New in-channel SWH will be modeled to function at three different flow levels. The mean river flows for these calendar periods will be added to the Gavins Point discharge to account for increasing river flows downstream from Gavins Point.
 - a. 1/3 of the new SWH will be placed to provide 0-5 feet of depth at low summer flow. Low summer flow is defined as 21-kcfs release from Gavins Point, plus July incremental flows downstream.
 - b. 1/3 of the new SWH will be placed to provide 0-5 feet of depth at mid-August. Mid-August is defined as the median August release from Gavins point, plus August incremental flows downstream.
 - c. 1/3 of the new SWH will be placed to provide 0-5 feet of depth at the spring pulse. Spring pulse is defined as the median May release plus 20-kcfs from Gavins Point, plus May incremental flows downstream.
 - d. In order to simplify HEC-RAS model construction, the width of each new SWH area will be determined as roughly 1/3 for each of the above flow profiles with side slope to attain the desired total top width of the widened area
 - e. SWH already in the system through 2012 was placed to provide 0-5 feet of depth at mid-August. Mid-August is defined as the August 50% duration flow based on gauge statistics.
7. Incremental flows will be from the USACE Missouri River Basin Water Management Division report titled Missouri River Incremental Flows Below Gavins Point (2014). Flow changes will be made at major tributary locations, portioned by tributary basin area.
8. Model all new in-channel and off-channel SWH based on the projected channel degradation expected for the future without project condition, making the assumption that constructed habitat will be modified as necessary in the future to avoid loss of habitat to channel degradation.
9. New in-channel SWH is to be represented as channel widening. SWH will be modeled as 250-ft wide in the reach from Gavins to Rulo and 300-ft wide from Rulo to St. Louis. Habitat will be placed as sloping from the elevation of water surface indicated by the model by the reference flows (for the three different flow levels described above).
10. New off-channel SWH will be represented as chutes in the Kansas City District, and chutes and backwaters in the Omaha district. Chutes will be represented with a fully developed top width of 300-ft.
11. Existing chutes that are currently represented in the model will be modified to represent an anticipated fully developed width of 300-ft with inverts modified for projected degradation.

FORT PECK FLOW ENHANCEMENTS AND WATER TEMPERATURE CONTROL DEVICE FEASIBILITY

The BiOp recognized water temperatures and flows as controlling factors for spawning cues, larval pallid sturgeon development as well as supporting forage in the Missouri River below Fort Peck Dam. The BiOp called for mini- and full-test of Fort Peck flow enhancements in addition to a study of the feasibility of temperature control device at Fort Peck.

Because of a drought followed by damages to the Fort Peck spillway during the 2011 high release events, the mini- and full-tests have not been completed. Unlike the Gavins Point release scenarios in which flow parameters were articulated in the BiOp, the BiOp relied heavily upon results from the Fort Peck flow tests to ultimately determine the long term flow implementation plan from Fort Peck. Therefore, it would be speculative at this time to determine modeling parameters for a long term flow implementation plan from Fort Peck.

Our understanding of the current science indicates larval drift distances are thought to be the leading factor in the lack of natural recruitment in the pallid sturgeon population below Fort Peck. Options to increase drift distances could include modifying infrastructure and operations at Fort Peck Dam to improve release timing and duration and to increase water temperature have been evaluated. We understand that your analysis of these options results in unacceptable dam safety risks and threatens compliance with congressionally authorized project purposes including flood control. Recent modeling for the effects analysis indicated that even if these issues could be overcome, actively managing the hydrology below Fort Peck Dam to provide the appropriate volume and temperature at the correct time would be a significant challenge containing hydrological, physical and biological uncertainty with a small probability of success. Additionally, for necessary larval drift distance to be achieved in this reach, the pool elevation of Lake Sakakawea would need to be lowered to historically low levels.

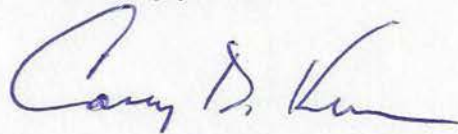

EMERGENT SANDBAR HABITAT PARAMETERS

1. The BiOp has a goal of 11,886 acres of ESH, which was further subdivided into acreage goals by river reach to be achieved by the year 2015 Existing Habitat/Existing Conditions
 - a. Below Gavins Point Dam – 80 acres of habitat per river mile;
 - b. Below Garrison Dam - 50 acres of habitat per river mile;
 - c. Below Fort Randall Dam - 20 acres per river mile;
 - d. Lewis & Clark Lake - 80 acres per river mile;
 - e. The USFWS 2003 BiOp Projected Actions Alternative modeling effort should focus on the above acreage goals. How those acreage goals are achieved is at USACE's discretion. Fledge ratios were included within the BiOP to reduce incidental take.

- f. Acreages should be measured in late July and consist of 60 percent dry sand.
2. The Corps will assume construction or maintenance activities to perpetuate the acreages determined.
3. Due to a lack of tern or plover presence in the Ft. Peck reach, no habitat would be included or modeled for the Ft. Peck reach.

Please contact Wayne Nelson-Stastny at (605) 660-5349 for further questions and clarification regarding the modeling of this alternative. The Service looks forward to our continuing collaboration with the Corps and other conservation partners in support of this important effort.

Sincerely yours,

Casey D. Kruse

RE: Planning Aid Letter Regarding Task B3 in the
Missouri River Recovery Program FWCA Scope or
Work – FY 2015

Dear Ms. Fitzner:

The U.S. Fish and Wildlife Service (Service or USFWS) provides this planning aid letter (PAL) to assist in the development of the U.S. Army Corps of Engineers' (Corps or USACE) Missouri River Recovery Management Plan and associated Environmental Impact Statement (MRRMP-EIS) in accordance with the Fiscal Year 2015 Fish and Wildlife Coordination Act (FWCA) scope of work agreed to by our agencies. This letter fulfills Task B3 contained in the scope of work. As a cooperating agency on the MRRMP-EIS, the Service provides the following comments pursuant to the FWCA of 1958, as amended (48 Stat. 401; 16 U.S.C. 661 et seq.), the National Environmental Policy Act (NEPA) of 1969 (42 U.S.C. 4321-4347), and the Endangered Species Act (ESA) of 1973, as amended (87 Stat. 884; 16 U.S.C. 1531 et seq.). Appendix 1 of this letter contains a list of definitions that will help to clarify the terms used in this letter.

The purpose of the MRRMP-EIS is to develop a suite of actions to meet the Corps ESA responsibilities regarding the threatened Northern Great Plains (NGP) population of the piping plover (*Charadrius melodus*), and the endangered interior least tern (*Sternula antillarum*) (ILT) and the pallid sturgeon (*Scaphirhynchus albus*), and the authorized purposes of the operations of the dams using Corps authorities. The geographic scope of the MRRMP-EIS encompasses the main stem portions of the Missouri River from Fort Peck, Montana to St. Louis, Missouri. The MRRMP-EIS will assess the current Corps programmatic impacts, cumulative effects and a range of potential alternatives. The MRRMP-EIS will include an adaptive management process for all Missouri River Recovery Program (MRRP) activities to ensure management decisions and actions are continuously improved by the learning that takes place from research and regular monitoring of the river.

This PAL does not constitute the final report of the Secretary of the Interior as required by Section 2 (b) of the FWCA for the MRRMP-EIS, nor does it constitute reconsultation of the 2000 and 2003 Amended Biological Opinion on the Operation of the Missouri River Main Stem Reservoir System, Operation and Maintenance of the Missouri River Bank Stabilization and

Navigation Project (BSNP), and Operation of the Kansas River Reservoir System (BiOp) under section 7 of the ESA.

In 2011, the Independent Science Advisory Panel (ISAP) provided a report per the request of Missouri River Recovery Implementation Committee (MRRIC) on the efficacy of the managed Spring Pulse and Adaptive Management. In its final report the ISAP recommended that the Service should specify the species objectives and targets for jeopardy avoidance, survival, and recovery in relation to Missouri River project impact and that the species objectives should be consistent with the findings of the ongoing Effects Analysis (EA) (Buenau et al. 2014, Fisichenich et al. 2014).

This letter transmits the quantitative population and habitat targets for the Missouri River piping plover sub-population to assure that each management action and alternative in the MRRMP-EIS is working towards meeting the agreed upon species objectives during implementation. We are pleased to provide these targets using the best available information to help the Corps in their efforts to better define management actions on the Missouri River to avoid jeopardizing these species due to the operation of the main stem dams and the operation, and maintenance of the BSNP. These targets are subject to change as necessary within the adaptive management process depending on monitoring and research information obtained during the implementation phase.

The Service greatly appreciates the ongoing effort of the EA team in supporting the development of these quantitative targets. This effort, led by Dr. Kate Buenau and Dr. Craig Fisichenich, has resulted in the creation of cutting edge population and habitat models that were vital to our analysis and establishment of these targets. Advancing this effort and continued refinement of these models will be imperative to a successful adaptive management program and to the implementation of effective management actions. The Service fully supports the utility and further development of these important analytical and predictive capabilities.

Jeopardy Versus Targets

The determination of jeopardy or adverse modification is based on the effects of the action on the continued existence of the entire population of the listed species or on a listed population, and/or the effect on critical habitat as designated in a final rulemaking. (USFWS Consultation Handbook, page 4-34)

The Service does not define jeopardy as a particular number, target, or a particular threshold. Rather, under the ESA, jeopardy occurs when there is an action that reasonably would be expected, directly or indirectly, to appreciably reduce the likelihood of both the survival and recovery of a listed species in the wild by reducing the reproduction, numbers, or distribution of that species. If a species population starts declining, jeopardy may be occurring.

Jeopardy of a species is a determination the Service makes after going through a process under the ESA of accessing the suite of alternative actions for a proposed federal project. Through that process the Service will determine what actions a federal agency needs to implement in relationship to where the species needs to be to remove any negative impacts to the species due to the agency proposed actions. A "jeopardy" determination is based on four factors: 1) status of the species, 2) environmental baseline, 3) effects of the Federal action, and 4) cumulative actions. These quantitative population and habitat targets of themselves do not constitute a

jeopardy determination; rather it is our intent to provide these targets to assist in the development of alternatives that achieve the fundamental objectives. The Service will be making a draft jeopardy determination after a preferred alternative has been identified. The final jeopardy determination will be made when a alternative has been selected in the Final EIS.

Use of the Piping Plover Targets for the Interior Least Tern and the Delisting Process

As part of the ILT delisting process, under the conservation mandate of section 7(a)1 of the ESA, there are efforts under way to develop conservation plans throughout the least tern population range. Section 7(a)1 of the ESA requires Federal agencies to use their authorities to develop and carry out conservation programs for listed species. The Corps Mississippi Valley Division on the lower Mississippi River, the Louisville District for the lower Ohio River, and the Southwestern Division for the Red and Arkansas rivers are developing 7(a)1 plans with post-delisting management commitments. After the Corps management strategies are drafted, there will be a 7(a)1 consultation with the relevant Service office. When these management plans are finalized, nearly all of the ILT population will be covered under post-delisting management commitments.

As previously discussed, we are anticipating that the MRRMP-EIS will serve as the conservation plan that will meet this ILT delisting requirement for the Missouri River. The MRRMP-EIS should discuss how the management practices contained therein are beneficial to ILT conservation, as well as demonstrate monitoring commitments which will continue post-delisting.

Much effort has been expended in the last year to develop objectives, metrics, and targets for the NGP piping plover for the MRRMP-EIS. We believe that managing for sufficient nesting habitat to sustain a NGP piping plover population in the Missouri River will also provide sufficient nesting habitat for the ILT in the Missouri River. Piping plovers and least terns are sympatric nesters, often using the same breeding sites throughout the Missouri River basin. Therefore, the efforts listed in this document will be referring to the needs of the piping plover only from here on. However, as mentioned above, to serve as the conservation plan required for delisting of the ILT, it will be important to include an assessment of how the management actions contained within the MRRMP-EIS may affect the ILT.

Piping Plover Fundamental Objective, Sub-Objectives, Metrics and Targets

The following is a summary of the Fundamental Objectives for both bird species and the Sub-Objectives, Metrics and Targets for the piping plover. In order to facilitate a clear understanding of the Service's determination of the piping plover objectives, metrics, and targets, the definitions of these terms can be found in Appendix 1. A more detailed description of the methods that were used to determine these targets will be provided in a future document.

After considering all the comments and input from species experts in two workshops the Service conducted in the summer of 2013, external reviewers, the MRRIC Science and Adaptive Management (SAM) Work Group, the MRRIC Strategic Programmatic Assessment (SPA) Task Group, and ISAP; the Service and the Corps developed the following **Fundamental Objectives** for the two listed bird species:

- Avoid jeopardizing the continued existence of the threatened Northern Great Plains population of the piping plover due to the US Army Corps of Engineers actions on the Missouri River.
- Avoid jeopardizing the continued existence of the endangered Interior Least Tern due to the US Army Corps of Engineers actions on the Missouri River.

While these fundamental objectives are consistent with the Service's current established recovery goals for the piping plover and least tern, they are prepared specifically to avoid and prevent jeopardy to the species due to Corps' operation and maintenance of the Missouri River System. These fundamental objectives and subsequent sub-objectives described below are the desired outcomes from the Corps' actions as part of the MRRMP-EIS. We believe that if the targets for the sub-objectives described below are attained it will result in the achievement of the stated fundamental objectives. The Service anticipates regular assessment and refinement of the sub-objectives, mean objectives, performance metrics and target levels through the adaptive management process. For this to occur, monitoring must be designed to measure metrics and assess whether targets are achieving the anticipated outcomes. This data would then be used to make any necessary adjustments to the Corps actions to meet the fundamental objectives. The Service looks forward to working with the Corps as development of these monitoring plans is progressed.

The following sub-objectives, means objectives, metrics, and targets are based on the following documents and events:

- information in the 2000 and 2003 amended Biological Opinion
- recent studies and research
- conceptual ecological models (CEMs) developed by both agencies with the help of internal and external species experts
- June 11, 2013 memo from ISAP to the SAM Work Group and MRRIC
- June 27, 2013 memo from ISAP to the Strategic Programmatic Assessment (SPA) Task Group
- discussions at the Species Objectives Workshops in July 2013
- interagency charrette in September 2014
- Corps' January 10, 2014 "Sideboards" document, and the geographic scope of the main stem of the Missouri River from the upper end of Fort Peck reservoir to the confluence with the Mississippi River
- Draft Interim Effects Analysis Integrated Report: Piping Plovers and Least Terns October 2014 (EA) (Buenau et al. 2014)
- Modeling to Support the Development of Habitat Targets for Piping Plovers on the Missouri River (Buenau 2015)
- Preliminary draft NGP Piping Plover Recovery Plan (in review)
- 2015 Draft Science and Adaptive Management Plan: Missouri River Recovery Program. Version 3. (Fischenich et al. 2015)

The EA (Buenau et al. 2014, Fischenich et al. 2014), including the hydraulic, emergent sandbar habitat (ESH) and population models, provided an empirical relationship linking hydrology, habitat, and bird populations. These models, created specifically for the Missouri River, consider the dynamic river processes and variable amounts of nesting habitat from year to year along with

density dependent reproductive rates to calculate the acres of ESH necessary for a resilient population of piping plovers. Population resiliency is primarily determined by habitat availability rather than an initial population size (Buenau 2015). As a result and as indicated in the targets below, we propose using acres of ESH as a target to ensure a resilient population of birds on the Missouri River for the adaptive management process. Acres of ESH are calculated in two ways:

Standardized ESH: The area above water when releases from Gavins Point Dam are 31.6 kcfs, Fort Randall Dam are 30.5 kcfs, and Garrison Dam are 23.9 kcfs. Used to track the amount of ESH structure in the river independent of flows.

Available ESH: The area above water during maximum July release for a specified year. Estimate of usable habitat for the birds during the nesting season. Reported as acreage of ESH exceeded during a percentage of years, e.g. 10, 25, 50, 75%.

Geographic distribution of the Missouri River piping plover population (sub-population of the NGP population) is described by two distinct geographic regions:

Northern Rivers Region: Missouri River from Fort Peck Lake Montana to Fort Randall Dam, South Dakota.

Southern Rivers region: Missouri River from Fort Randall Dam, South Dakota to Ponca, Nebraska.

- **Sub-objective 1 (Population):** Maintain a total population number of Missouri River piping plovers that keeps the population resilient on the Missouri River in the long term.

Means Objective: Provide enough ESH habitat on the Missouri River to maintain a 95% probability (resiliency) that a population of at least 50 individuals will persist for at least 50 years on the Missouri River.

Metric: Number of standardized and available ESH acres measured annually.

Target:

		Acres Of Sandbar Habitat		
		Lower 95% CI	Median	Upper 95% CI
Standardized ESH Acres		675	1433	6033
Percent	75%	510	710	1330
Exceedance	50%	930	1430	2675
of Available	25%	1580	2880	5070
ESH Acres	10%	2420	4550	8470

- **Sub-objective 2 (Reproduction):** Maintain a long-term trend in population growth rate (λ) that is at least stable.

Means Objective: Maintain a stable or increasing population.

Metric: Population growth rate: the change in population size between years; calculate annually.

Target: $(\lambda) \lambda \geq 1$

- **Sub-objective 3 (Chick Survival/Reproduction):** Increase and maintain the success of breeding pairs on Missouri River.

Means Objective: Increase nest success and chick survival to fledge.

Metric: Fledge Ratio: Number of fledglings observed/(number of adults/2).

Target Range: ≥ 1.25 chicks fledged per breeding pair (Catlin et.al. 2015).

- **Sub-objective 4 (Distribution):** Maintain a geographic distribution of plovers in the river and reservoirs in which they currently occur in both the Northern and Southern River Regions.

Means Objective: Provide enough ESH habitat on the Missouri River to maintain a 95% probability (resiliency) that a population of at least 50 individuals will persist for at least 50 years in each region.

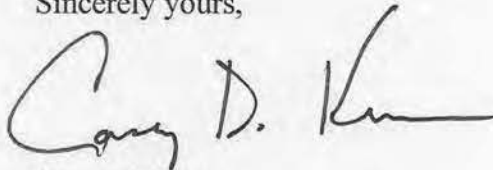

Metric: Number of standardized and available ESH acres measured annually.

Target:

		Acres of Sandbar Habitat					
		Northern Rivers Region			Southern Rivers Region		
		2.5%ile	Median	97.5%ile	2.5%ile	Median	97.5%ile
Standardized ESH Acres		200	428	1996	264	782	3907
Percent	0.75	140	210	470	280	370	700
Exceedance	0.5	380	630	1000	460	720	1580
of Available	0.25	770	1420	2010	780	1370	3285
ESH Acres	0.1	1340	2230	3625	1130	2320	5275

The Service looks forward to continuing to work collaboratively in support of this important effort, ensuring the success and ultimate implementation of the MRRMP-EIS for the conservation of Missouri River fish and wildlife resource. If you have any questions, please feel free to contact me at (605) 665-4856.

Sincerely yours,

Casey D. Kruse

Kansas City, Missouri 64106

RE: Planning Aid Letter regarding development of
the Missouri River Recovery Management Plan/EIS

Dear Ms. Fitzner:

The U.S. Fish and Wildlife Service (Service or USFWS) provides this planning aid letter (PAL) to assist in the development of the U.S. Army Corps of Engineers' (Corps or USACE) Missouri River Recovery Management Plan and associated Environmental Impact Statement (MRRMP-EIS). The Service provides the following comments pursuant to the Fish and Wildlife Coordination Act (FWCA) of 1958, as amended (48 Stat. 401; 16 U.S.C. 661 et seq.), the National Environmental Policy Act (NEPA) of 1969 (42 U.S.C. 4321-4347), and the Endangered Species Act (ESA) of 1973, as amended (87 Stat. 884; 16 U.S.C. 1531 et seq.).

This PAL does not constitute the final report of the Secretary of the Interior as required by Section 2(b) of the FWCA for the MRRMP-EIS, nor does it constitute reconsultation of the 2000 and 2003 Amended Biological Opinion on the Operation of the Missouri River Main Stem Reservoir System, Operation and Maintenance of the Missouri River Bank Stabilization and Navigation Project (BSNP), and Operation of the Kansas River Reservoir System (BiOp) under section 7 of the ESA.

The purpose of the MRRMP-EIS is to develop a suite of actions to meet ESA responsibilities for the threatened Northern Great Plains (NGP) population of the piping plover (*Charadrius melodus*), and the endangered interior least tern (*Sternula antillarum*) and pallid sturgeon (*Scaphirhynchus albus*), and the authorized purposes of the operations of the dams using Corps authorities. The geographic scope of the MRRMP-EIS encompasses the main stem portions of the Missouri River from Fort Peck, Montana to St. Louis, Missouri. The MRRMP-EIS will assess the current Corps programmatic impacts, cumulative effects and a range of potential alternatives. The MRRMP-EIS will include an adaptive management process for all Missouri River Recovery Program (MRRP) activities to ensure management decisions and actions are improved by the learning that takes place from research and monitoring of the river.

After discussions with the Missouri River Recovery Implementation Committee (MRRIC) and our review of recent additions to the available scientific information, the Service provides this

letter to clarify and further define our recommendations regarding development of management actions intended to provide habitat for the piping plover and interior least tern as part of the development of the MRRMP-EIS. The information provided herein should be considered in concert with previous statements provided in our letter to Corps dated November 10, 2010.

For clarity of this letter, the Service defines off-channel habitat as areas that are not connected to the main channel hydrologically, energetically, and/or through sediment degradation/aggradation processes. In-channel habitat is defined as areas within or adjacent to and connected with the main channel hydrologically, energetically, and/or to the sediment transport processes; and suitable for productive nesting as defined in the 2011 Final Programmatic Environmental Impact Statement for the Mechanical and Artificial Creation and Maintenance of Emergent Sandbar Habitat in the Riverine Segments of the Upper Missouri River. (USACE 2011)

As you know, the Effects Analysis (EA) lead by Dr. Kate Buenau and Dr. Craig Fischenich and being conducted as part of the MRRMP-EIS planning process has significantly advanced our analytical and predictive capabilities. This effort has utilized more than 20 years of Corps piping plover demographic data and linked it with habitat availability to create predictive models that estimate the extent and temporal availability of habitat necessary for persistence of piping plovers on the Missouri River. This relationship between species persistence and habitat availability relies on our understanding of piping plover reproductive ecology on riverine portions of the Missouri River particularly below Garrison, Fort Randall and Gavins Point Dams. While the relationship between habitat availability and piping plover reproductive success is less certain for reservoir habitat, the model does account for those birds and their contribution to population persistence.

It is from these predictive models that we have been able to provide numerical bird targets in terms of available habitat acres (see Planning Aid Letter dated November 13, 2015). To meet these targets and maintain least terns and piping plovers on the Missouri River, the Service recommends at this time that the Corps develop management actions for the MRRMP-EIS that prioritize creation and maintenance of habitat within the unchannelized river below Garrison, Fort Randall (including the sediment delta of Lewis and Clark Lake) and Gavins Point Dams. The Service encourages continued assessment and model development that considers all potential bird habitat associations within the MRRMP-EIS planning area, concurrent with implementation of adaptive management in continued efforts to better understand and meet species and human considerations needs on the Missouri River.

The MRRP Independent Science Advisory Panel's (ISAP) evaluation of the Draft Bird Adaptive Management Cycle Example (ISAP 2015) contained recommendations to consider "off-channel" habitat for the birds as a management action in the MRRMP-EIS. Additionally on several occasions since 2010, MRRIC has recommended the Service consider "off-channel" nesting habitat as a MRRP management action. These discussions have included habitat within reservoir pools, off-channel habitat similar to sandpits adjacent to the central Platte River and habitat creation in the navigation channel below Ponca, Nebraska. While the Service considers only the sandpit habitat to be off-channel, we do not recommend the development of management actions within the MRRMP-EIS that include the purposeful creation of tern and plover habitat in any of these habitat associations at this time. However, as our knowledge of these habitat associations increases and in the case that it is demonstrated that these habitat associations can function

successfully as tern and plover reproductive habitat, the Service will revisit its current position regarding nesting habitat within the MRRP at that time.

In certain years, Lake Sakakawea and Lake Oahe are important nesting areas particularly for piping plovers. The nesting habitat on these reservoirs is currently maintained by the inter-annual regulation of storing and releasing river basin runoff. Reproductive success is typically highest during drier basin conditions that follow periods of higher reservoir pool levels. Declining reservoir pools expose the newly scoured substrates preferred by the plovers. However, tern and plover nests are frequently at risk of being flooded in the reservoirs with storage of seasonal uncontrolled run-off and the Corps regulation of water levels to meet the Master Manual (USACE 2006) requirements. Since MRRP monitoring of the tern and plover populations within the Missouri River began in 1986, approximately 80 percent of the total incidental take of piping plover eggs and chicks and 58 percent of least tern eggs and chicks were due to rising pool levels in reservoirs. Until we better understand reservoir habitat dynamics in relation to bird densities and reproductive output, and until we develop sustainable habitat-creation techniques on reservoirs that can demonstrate desired levels of reproduction, and because it is necessary to allow the reservoirs to fluctuate in order to protect the reproductively high value habitats below the dams; the Service does not recommend purposefully developing habitat on reservoirs as a management action in the MRRMP-EIS at this time. However, all birds produced and supported on habitat associated with the reservoirs contribute towards meeting MRRMP-EIS species objectives as conferred by the Service in the planning aid letter dated November 13, 2015.

Developing off-channel habitat similar to what occurs adjacent to the central Platte River is frequently referred to as a management strategy that should be considered for piping plover and least tern habitat on the Missouri River. While similarities provide the opportunity for extrapolation of ideas, the Missouri River is different from the central Platte River both ecologically and in regards to its water resource development. The two rivers do not have the same sedimentation or hydrological processes, or predator regime (Jenniges and Plettner 2008). The 90-mile reach of the central Platte River used by the birds is hydrologically limited regarding in-channel flows to isolate nesting colonies and habitat forming and maintenance flows to scour and redistribute habitat within the river channel. This region of the Platte River has a long history of active commercial sand and gravel mining sites, which most of the terns and plovers on the central Platte use for nesting. These off-channel habitat areas on the central Platte River provide better nesting conditions than the marginal habitat occurring on the river itself. Uncertainties regarding the potential contributions of this habitat type on the Missouri River to piping plover and least tern persistence remain. Reproductive potential, habitat preferences and dispersal, land acquisition, feasibility of creation and maintenance would all need to be resolved. As such the Service does not recommend including sand pit habitat management as a management action in the MRRMP-EIS at this time.

The reach of the Missouri River below Ponca, Nebraska is defined by the Bank Stabilization and Navigation Project. Nesting of least terns on this reach has only recently been recorded. This has occurred on sand splays resulting from dike ruptures during the 2011 flood and on sediment aggradation areas within the shallow water habitat project at Deer Island. No piping plover nesting activity has been recorded on this reach of the Missouri River since the species was listed. Many of the same uncertainties existing for reservoir and sandpit habitats exist for habitat in this geographic extent. The value of this habitat to piping plover and least reproduction is unknown. Habitat preferences and dispersal, forage availability, land acquisition, feasibility of

creation and maintenance would all need to be resolved. Considering these uncertainties, the Service does not recommend purposefully developing habitat below Ponca, Nebraska as a management action in the MRRMP-EIS at this time.

Once again, the Service is looking forward to continuing to work collaboratively with you and the MRRIC in support of this important effort to ensure the success and ultimate implementation of a management plan for the recovery of the fish and wildlife resources of the Missouri River, while also taking into consideration the human resources. If you have any questions, please feel free to contact me at (605) 665-4856.

Sincerely yours,

v/r *Casey D. Kruse*

RE: Planning Aid Letter Regarding the
Missouri River Recovery Management Plan
and Environmental Impact Statement
(MRRMP-EIS) fish and wildlife proxy

Dear Ms. Fitzner:

The U.S. Fish and Wildlife Service (Service or USFWS) provides this planning aid letter (PAL) regarding the development of the U.S. Army Corps of Engineers' (Corps or USACE) Missouri River Recovery Management Plan (Management Plan) and associated Environmental Impact Statement (EIS) in accordance with the Fiscal Year 2015 Fish and Wildlife Coordination Act (FWCA) scope of work, task B4. As a cooperating agency on the Management Plan and EIS, the Service provides the following comments in coordination with the seven Missouri River Mainstem state fish and wildlife agencies pursuant to the FWCA of 1958, as amended (48 Stat. 401; 16 U.S.C. 661 et seq.), the National Environmental Policy Act (NEPA) of 1969 (42 U.S.C. 4321-4347), and the Endangered Species Act (ESA) of 1973, as amended (87 Stat. 884; 16 U.S.C. 1531 et seq.). Enclosures include letters and emails with comments and suggestions we received from five state fish & wildlife agencies.

This PAL does not constitute the final report of the Secretary of the Interior as required by Section 2 (b) of the FWCA, nor does it constitute reconsultation of the 2000 and 2003 Amended Biological Opinion on the Operation of the Missouri River Main Stem Reservoir System, Operation and Maintenance of the Missouri River Bank Stabilization and Navigation Project (BSNP), and Operation of the Kansas River Reservoir System (BiOp) under section 7 of the ESA.

The following comments are specifically in regards to the draft human consideration objective developed for the environmental conservation/fish and wildlife topic. They are a compilation of comments provided by state agencies and Service staff.

Comments

The current methodology uses flows at the 50th percentile over the period of record to determine benefits/impacts to fish and wildlife. Analyzing those flows provides some insight into the

effects of the alternatives on fish and wildlife; however the 50th percentile may overly focus on impacts to species that are generalists. Because more extreme events play a more significant role in benefiting species adapted to extremes, we recommend analyzing the effects of upper/lower decile percentile flows and upper/lower quartile percentile flows to better understand the full range of potential biologic responses.

We recommend that open water habitat be broken into a range of depth and velocity classes. With many native Missouri River fish species in decline, it is important to consider the quantity of each habitat type and its associated functionality to more accurately estimate effects on native fish species. Depth, velocity and seasonality of inundation all play critical roles in determining impacts to floodplain and riverine fish and wildlife species. Classification of aquatic habitats based on water depth and velocity, and analyzing the acreage or percentage of each class/category would provide an index to habitat diversity within the open water category. This will be especially useful since the diverse assemblage of native Missouri River fishes have a wide range of habitat requirements, but may have particular requirements for different life stages. One category that has not normally been considered before is deeper slow water. This habitat appears to be important as a haven for many species and life stages as well as in many different seasons. We propose the Corps include a matrix of the following depth and velocity categories recognizing at this point that velocity analysis may be difficult to complete:

- Velocities: 0-1 ft/sec, 1-2 ft/sec, 2-3 ft/sec, >3 ft/sec
- Depths: 0-3 ft., 3-6 ft., 6-12 ft., 12-20 ft., and >20 ft.

Seasonality of inundation or lack thereof plays an important role in determining fish and wildlife benefits. Currently, the proxy averages inundation over a growing season generally spanning April-October. To better determine the impacts to fish and wildlife, including various life stages, we recommend the year be separated into the following five periods for the length of the Missouri River being analyzed:

- Overwintering late: January 1 – February 28/29
- Early spawning: March 1 – May 14
- Late spawning: May 15 – June 30
- Summer rearing and growth: July 1 – September 30
- Overwintering early: October 1 – December 31

Floodplain habitats can and do support a wide array of fish, wildlife and plants. Through the BSNP, degradation and construction of levees have combined to reduce aquatic habitat diversity and connectivity within the Missouri River floodplain. It is important to ensure that the fish and wildlife proxy has the ability to discriminate between alternatives in regards to habitat diversity and connectivity. Currently, much of the effects analysis appears focused between river levees. There is a large portion of the floodplain behind levees, especially in the lower river, that may have impacts that are not being assessed for the various alternatives. This could come about through groundwater connections of various flows and tributary backwater at high Missouri River stages. Thus, we strongly recommend adding an additional metric that measures public fish and wildlife conservation lands to determine the effects of the various alternatives on fish and wildlife via changes in terrestrial as well as aquatic habitats, and their intersection. This metric should also include a measure of potential connectivity for Missouri River fishes with an examination as to whether or not connectivity provides fish access. Finally, a helpful addition to better understanding the impact of different alternatives on floodplain and wetland habitats may be to consider different assemblages of plant communities in the floodplain and wetland habitats. With regards to the floodplain habitat types and inundation definitions provided, they appear legitimate for the analysis.

The Service, in coordination with Missouri River mainstem state fish and wildlife agencies, is looking forward to continuing to work collaboratively in support of this important effort to ensure the success and ultimate implementation of the Management Plan for the recovery of the fish and wildlife resources of the Missouri River, while also taking into consideration the human resources. Please contact me at (605)665-4856 or Wayne Nelson-Stastny at (605)660-5349 for further questions and clarification.

Sincerely yours,

v/r *Casey D. Kruse*

Dear Mr. Nelson-Stastny,

Thank you for allowing us to provide comments on the Missouri River Recovery Management Plan (MRRMP) and Environmental Impact Statement (EIS) Fish and Wildlife Proxy under the guidance of the Fish and Wildlife Coordination Act. The South Dakota Department of Game, Fish, and Parks (SDGFP) is charged with managing the fish and wildlife resources of the State of South Dakota and their associated habitats for the benefit of the public. The opportunity to comment on the Fish and Wildlife proxy allows SDGFP to actively participate in the fish and wildlife management process for this inter-jurisdictional river so important to our State.

The United States Army Corps of Engineers (USACE) has decided to use the HEC-RAS modeling to classify acres of multiple habitat types based on the amount of time land is inundated or wetted. While there are many factors that can influence which successional plant community will be present, utilizing the HEC-RAS modeling may provide a good estimate of changes that could occur due to USACE actions. We generally believe that this is a reasonable approach and that the terrestrial habitat classifications are adequate, however, we have some concerns about the current state of aquatic habitat classifications within the proxy.

We believe that there needs to be more consideration given to aquatic habitat types. Under the proposed proxy, all aquatic habitat is classified as "open water." With 51 of 67 fish species native to the Missouri River in decline, it is important to consider the quantity of each habitat type and its associated functionality in order to estimate effects on native fish species. There are two approaches that could help improve the aquatic aspect of the fish and wildlife proxy. Aquatic habitats could be classified as lakes, ponds, scour holes, main channel, side channels and tributaries, however this method may prove difficult and time consuming. An alternative method would be to classify habitats based on water depth and velocity. Analyzing either the acreage or percentage in each level of water depth and velocity could give an index to habitat diversity within the open water category. This may be a more appropriate method, since not all species have the same habitat requirements.

We were informed during the briefing webinar that there is a tool being developed by another USACE office that will facilitate the classification of aquatic habitats. Unfortunately there is great uncertainty about when the tool will be available and if the

data will be available for the round 2 tradeoff discussions or the draft EIS. Due to the importance of the aquatic habitats in the Missouri River, we recommend that the USACE coordinate within its agency to provide a timeline of when more detailed aquatic habitat classifications will be included in the fish and wildlife proxy.

Another component that appears to be missing from the proxy is the seasonality of inundation, and more specific to the aquatic habitats, depth and velocity. The list of current alternatives that are being discussed includes alternatives with both spring and fall releases for habitat creation. Each alternative will likely have different seasonal patterns in regards to inundation, depth, and velocity and could have varying effects on fish and wildlife.

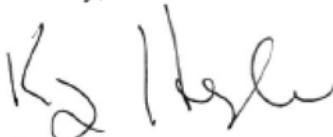

The Bank Stabilization and Navigation Project along with degradation below the dams have reduced aquatic habitat diversity and connectivity within the Missouri River floodplain. Thus it is important to ensure that the fish and wildlife proxy has the ability to discriminate between alternatives in regards to habitat diversity and connectivity. The acreage or percentage of the three wetland types (emergent wetland, scrub-shrub wetland, and riparian woodland/forested wetland) may provide the best indication of differences in floodplain connectivity between the alternatives. Additionally, early alternative discussions included the effects of degradation on human consideration proxies. Does the current fish and wildlife proxy include effects of degradation? Also, how does the model account for reduced sediment availability over the next 50 years?

During the briefing webinar, we were told that we would be provided with information about the length of the cross sections which ultimately define the scope of the habitat modeling. We look forward to receiving this information in a timely matter.

We appreciate the extended comment period and briefing webinars provided as requested. For future input requests, we suggest a similar process that includes a briefing webinar and adequate time to gather input from staff so the states can provide a comprehensive review of materials.

Thank you for this opportunity to provide comments on the fish and wildlife proxy to be used in developing the Missouri River Recovery Management Plan and EIS through the Fish and Wildlife Coordination Act. If you have questions regarding these comments or are in need of additional input please contact our Aquatics Section Chief John Lott 605.773.4508 or Senior Fisheries Biologist Chris Longhenry 605.734.4548.

Sincerely,

A handwritten signature in black ink, appearing to read 'K2 Hepler', written over a horizontal line.

Dear Wayne:

RE: Fish and Wildlife Coordination Act Comments

Thank you for the opportunity to review and discuss the draft model. First, we appreciate the difficulty of the task to develop a metric or measure to describe biological response to various management actions in a system as vast as the Missouri River. Further, we are confining our comments to how we see the proposal describing a response in the river segment adjacent to the Kansas border.

It appears that what has been presented is an attempt to use a single quantitative measure (water level or stage only) to make a qualitative assessment. The assumption being that more or less is better or worse for fish and wildlife. This approach lacks any qualitative measure. There is no assessment of the varying types of habitat available at a given water level stage. The very basic measures of depth, substrate and velocity and refinements of those typically used to assess habitat suitability are not included.

As an example, slide 10 of the presentation illustrates a "typical" cross section of the system. Within that "typical" cross section there is a wide range of flows or depths in which it appears there is no apparent change in available habitats or diversity of habitats. The apparent implication of the model is that conditions for the pallid sturgeon may be better or worse with more or less flow when the "typical" cross section only indicates vertical movement within a confined channel over a wide range of flows or stages, vertical movement within a confined channel. Similarly, the seasonal habitat needs or habitat needs for various life stages of a target species, such as the pallid sturgeon, appear to be lost with this model. There are differences in the habitat and food source requirements of many species at different stages of their life history. Larval, juvenile, adult and spawning habitat and food needs are not the same. It is not apparent to us the model captures either those needs or how changes affect those needs.

Also, as stated in slide 8 the 50th percentile flow (median flow) is used as the basis for the model. Median flows appear to favor those species which would be considered generalists. Those species which have their needs met over a wide variety of conditions. In this situation the goal is recovery of a species, and other declining species, that do not appear to have their needs met by median conditions in the systems as it exists. The model should assess effects on the target species using a metric (or metrics) that address the specific needs of that species. It is not apparent to us that median flows will accomplish this.

Thank you for the opportunity to provide comments. We look forward to working with you as this effort progresses.

Sincerely,

A handwritten signature in black ink, appearing to read "Steve Adams", written in a cursive style.

Steve Adams,
Chief of Planning

Enclosure 3

MDC FWCA input on FW Human Consideration received July 6, 2015

Jennifer Campbell <Jennifer.Campbell@mdc.mo.gov>

Jul 6, 2015

Wayne,

Thanks for the opportunity to review the U.S. Army Corps of Engineers (USACE) fish and wildlife proxies, objectives and metrics for native species other than the three federally listed species. From the conference call, our understanding of the purpose of these fish and wildlife proxies is to conceptualize how a range of river management alternatives, primarily related to flow, would affect native fish and wildlife species. We further understand that the proxies will be used in a trade-offs analysis (Round 1 and 2) and impacts assessment for the Missouri River Recovery Management Plan Environmental Impact Statement (EIS). The trade-offs analysis will seek to balance how management actions are likely to affect different interests on the river, including native species, to help guide future USACE river management efforts. The EIS will seek to demonstrate that a preferred alternative, among the suite of alternatives considered, is the least environmentally damaging practical alternative.

Through a paired Hydrologic River Engineering Center-River Analysis System (HEC-RAS) and Hydrologic Engineering Center -Ecological Function Model (HEC-EFM) modeling approach, the USACE will estimate available habitat acres from the given alternative flow regime by estimating water depths longitudinally along the Missouri River and laterally within the navigation channel, as well as duration of inundation. Some river segments will also estimate water depths within portions of the floodplain. The approach assumes that water depth predicted by the model will meet the needs of native species. The reference dataset of flows is 1933 – 2012, and the 50th percentile flow will be used to estimate the median potential habitat acreage. USACE estimates that the 50th percentile flow represents the typical flow.

Predicting impacts of river management alternatives to native fish and wildlife is a complex undertaking. While Department staff are not experts in these models, there do appear to be some fundamental limitations to the approach that should be addressed. We offer the following technical comments:

1. Potentially available habitats (suitable water depth) could more likely predict functional habitats with a measure of accuracy if the prescribed inundation depth and duration were to occur:
 - A. At a biologically useful time (“correct season”);
 - B. Along with suitable flow velocity;
 - C. On a bank slope conducive to vegetation that supports various life stages and feeding guilds;
 - D. In areas that are hydrologically connected to the River such that native fish and wildlife can access these areas.

2. How will results from the modeling effort be verified? Levees and ditches with drainage tube structures can be expected to prevent areas of suitable elevation from inundation at the corresponding river elevation in some areas. Modeled inundation may not always translate to fish access. Perhaps a combination of LiDAR and field observations could help to develop the fine scale inundation maps that could accurately predict habitat availability.
3. Will using a median (50th percentile flows) approach to reference flows capture the needs of those native, non-endangered species that may be in decline? Such species are rarely generalists. It would seem that a median approach for the period of record (since river modifications began) might be biased towards benefiting the species capable of exploiting the modified river conditions.
4. Defining fish and wildlife habitat by water depth and inundation alone could overestimate the number of acres of habitat capable of supporting fish and wildlife. It is not clear what a result of this model might measure or how it might be interpreted. How would the results provide insight into effects of different alternatives on fish and wildlife species?
5. How will the model account for the effect of soil types on sites that require a longer or shorter hydroperiod to develop the desired plant community? For example, very sandy wetland sites require longer duration of inundation (longer hydroperiod) to develop the desired wetland plant community. Conversely, wetland sites with heavy clay content would need a shorter hydroperiod to achieve the same result. Soil maps are themselves not of sufficient resolution or recent revision to reflect variable hydroperiod needs.
6. Habitat Classes should include a class dominated by annual herbaceous plant species found during short hydroperiods, such as 20-30 days of inundation during the growing season. This would be a wetland habitat class dominated by annual plants with some mix of perennials and share the same Quantitative Hydroperiod as the terrestrial habitat class listed as Forest.
7. Hydroperiods may warrant reconsideration. By observation, there are times during the year when certain habitats are inundated for shorter or longer periods of time than listed in the document.
8. The five fish growing seasons (late overwintering, early spawning, late spawning, summer rearing and growth, and early overwintering) described by Nebraska look consistent with what is observed in Missouri.
9. The effort could consider establishing the life cycle of plants in these wetland habitats.

Thanks for your coordination and for the opportunity to comment. Please contact me with any questions about these comments.

Jennifer

Enclosure 4

NEGPC FWCA input on Fish and Wildlife Human Considerations. Received June 26, 2015

Zuerlein, Gene <gene.zuerlein@nebraska.gov>

Jun 26, 2015

Wayne,

In regards to the fish growing season comments, NGPC used 5 timeframes in the MesoHABSIM study on the Niobrara River. They can be found in the final report by Parasiewicz et al. 2014 located on the NGPC web site (www.outdoornebraska.ne.gov), clicking on conservation, then clicking on water, and then scrolling down to the Niobrara River. In brief the timeframes are as follows:

Overwintering late – Jan1 – Febr 28/29

Early spawning – March 1 – May 14

Late spawning – May 15 – June 30

Summer rearing and growth – Jul 1 – Sept 30

Overwintering early – October 1 – Dec 31

In the report the periods (Table 20) are switched around a bit, but I put them in calendar order sequence for a normal calendar year.

Gene

to me, Adams, Chris, dfryda, Don, Gene, Kasey, jennifer.campb., Sam, Gerald.Mestl, John

All,

Today during the MRRIC fish and wildlife proxy webinar, the issue was brought up again that the open water habitat category should be split in to multiple classifications based on depth and velocity. The facilitators asked me to provide the parameters for the different depth and velocity classes. Since this has been discussed among this group in the past, I wanted to get your input on what depth/ velocity classes you feel would be most useful for comparing alternatives. I have included a draft set of classifications to get us started. I am open to any suggestions. Also, I would like input on how each of you thinks the year should be split to evaluate seasonal changes. Right now the proxy only includes a April- October growing season. I believe previous discussions indicated the importance of estimating the acreage of each habitat type during each of four seasons, but I can't remember the specific months suggested.

I apologize for the short turnaround, but I would like to send them this information by the end of next week.

Depth	velocity
0-2 ft.	0-0.5 ft./sec
2-5 ft.	0.5-1.5 ft./sec
5-10 ft.	1.5-3 ft./sec
10-20 ft.	>3 ft./sec
>20	

Thanks for your help

Chris

Enclosure 7

Zuerlein, Gene <gene.zuerlein@nebraska.gov>

Aug 12, 2015

to Chris, me, Adams, Chris, dfryda, Don, Kasey, jennifer.campb., Sam, Gerald.Mestl, John
Chris,

Different seasons for a fish life cycle. The one we used for an instream flow study was for many warm and cool season species inhabiting the Niobrara River and generally covers most species as follows:

Overwintering Late – Jan 1 – Feb 28

Early Spawning – Mar 1 – May 14

Late Spawning – May 15 – Jun 30

Summer Rearing and Growth – Jul 1 – Sept 30

Overwintering Early – Oct 1 – Dec 31

Normally spawning is on the upswing or downswing slope of a spring runoff event. If you consolidated over wintering into one, there would be 4 seasons, but in terms of water management on a calendar basis, we (Fish Division staff and Piotri-contractor) thought the above timeframes fit most species based on experience and literature.

Gene

Enclosure 8

Stukel, Sam

Aug 14 (6 days ago)

to Chris, Chris, me, Adams, dfryda, Don, Gene, Kasey, jennifer.campb., Gerald.Mestl

I agree with Chris that a deep and slow habitat should be considered as an additional category. Here in the unchannelized MNRR that would cover the #1 type of habitat we go to when we are in search of sturgeon – at any time of year. These would be the slow-water pools behind sandbars. In this reach, such a habitat might be characterized by a depth of 6 – 12' and a velocity of 1 - 2 ft./sec. They are a haven for many species. It seems to me that this type of habitat would be an important part of a diverse river reach.

Otherwise, I think the categories you listed would be helpful in comparing alternatives.

The seasonal component seems like an obvious need. I support using the periods listed by Gene.

Enclosure 9

Jennifer Campbell <Jennifer.Campbell@mdc.mo.gov>

8/20/2015

to Chris, me, Adams, Chris, dfryda, Don, Gene, Kasey, Sam, Gerald.Mestl, John
Chris,

MDC data collected through annual HAMP studies lend weight to the need for deep, slow velocity habitat. Some of the highest catch rates of YOY sturgeon species occur in river depths of 2-3 meters that had velocities of 0.5-0.7m/s. Staff suspect velocity could be more important than depth for this life stage.

More frequently staff observe greater depth water in the river correlates to higher velocities, so the results are of interest. Is there a model that defines the relationship between depth and velocity? For example, at point A with a velocity of 0.5 m/s would we get depth X. If we increase velocity to 1.0m/s at the same point would we get depth Y?

MDC staff agree with the habitat categories proposed by Nebraska for spawning times, rearing times, overwintering and migration. Note that these life stages are not limited to April – October, the period considered by USACE for a range of management alternatives, based on the navigation season. Each season and the habitat available during it has an effect on the life stages of pallids and other fish.

Thanks,
Jennifer

Ms. April Fitzner
Missouri River Recovery Program
Senior Program Manager
U.S. Army Corps of Engineers
601 E 12th Street
Kansas City, Missouri 64106

RE: Missouri River Recovery Management Plan
and Environmental Impact Statement (MRRMP-
EIS) Preliminary Draft Chapter 2: Alternatives

Dear Ms. Fitzner:

As a cooperating agency in the development of the U.S. Army Corps of Engineers' (Corps or USACE) draft Missouri River Recovery Management Plan and associated Environmental Impact Statement (MRRMP-EIS), the U.S. Fish and Wildlife Service (Service) provides the following overarching comments regarding the preliminary draft Chapter 2. We provide these comments in partial completion of Task B3 contained in the draft Fiscal Year 2016 scope of work for the Service pursuant to the Fish and Wildlife Coordination Act (FWCA) of 1958, as amended (48 Stat. 401; 16 U.S.C. 661 et seq.), the National Environmental Policy Act (NEPA) of 1969 (42 U.S.C. 4321-4347), and the Endangered Species Act (ESA) of 1973, as amended (87 Stat. 884; 16 U.S.C. 1531 et seq.). Enclosed is a list of specific comments regarding the draft Chapters 1 and 2.

This letter does not constitute the final report of the Secretary of the Interior as required by Section 2(b) of the FWCA for the MRRMP-EIS, nor does it constitute reconsultation of the 2000 and 2003 Amended Biological Opinion on the Operation of the Missouri River Main Stem Reservoir System, Operation and Maintenance of the Missouri River Bank Stabilization and Navigation Project (BSNP), and Operation of the Kansas River Reservoir System (BiOp) under section 7 of the ESA.

The Service appreciates the close coordination during the development of the MRRMP-EIS process and the opportunity to review early drafts of the MRRMP-EIS chapters. Continuing to work together in this effort will allow any significant issues that may impede accomplishing the objectives of the plan to be resolved early in the process and prevent delays in the schedule.

Range of Alternatives

It is the Service's understanding that the alternatives as structured in the MRRMP-EIS were developed to singularly analyze the effects of individual actions because of the difficulty of portraying a multi-faceted alternative with adaptive management to the public. As such, any one of the alternatives disparately displayed may not meet the purpose and need of the MRRMP-EIS.

Alternative 2, which represents the existing BiOp as projected, has a suite of actions that can be implemented to address the needs of the listed species, the endangered interior least tern (*Sternula antillarum*) and pallid sturgeon (*Scaphirhynchus albus*), and the threatened Northern Great Plains (NGP) population of the piping plover (*Charadrius melodus*); therefore, meeting the objectives of the MRRMP-EIS. It is our anticipation that a final selected alternative

will likely require a combination of actions from several of the analyzed alternatives at some frequency, duration, or scale. While the current suite of alternatives may not fully meet the purpose and need of the MRRMP-EIS at this time, the analysis should provide sufficient information on the scope, scale and duration of actions that can be combined to meet the objectives. As the Service and the Corps have discussed, we recommend that the Corps include language in the alternatives chapter and cumulative effects section that discusses the possibility of this approach.

Importance of the BSNP Missouri River Fish and Wildlife Mitigation Project

The 2003 Amended Biological Opinion (BiOP) considered the BSNP Missouri River Fish and Wildlife Mitigation Project (MRFWP) as an important interrelated and interdependent action during past consultations regarding actions on the Missouri River.

The goal of BSNP MRFWP is to restore fish and wildlife lands that were lost or damaged due to the channelization and bank stabilization of the Missouri River below Sioux City, Iowa. The legislation authorizes the purchase of 166,750 acres of land along the river from willing sellers. These lands are then restored with native vegetation, wetlands and water features that connect to the river. While the overarching focus of the BSNP MRFWP is on mitigating losses to the wide range of fish, wildlife, plants and associated habitats that comprise the Missouri River ecosystem, a vital component of the overall effort also provides benefits to the listed species.

The Service will be looking for a clear articulation of how the BSNP MRFWP will be utilized to enhance and enable actions to be completed, to achieve the objectives of this MRRMP-EIS.

Adaptive Management

The Service continues to be supportive and applauds the Corps' efforts in developing the Adaptive Management Plan (AM Plan) in concert with the MRRMP-EIS. While the Service recognizes that this review is focused on the proposed alternatives, we remain keenly interested in how adaptive management will be integrated within the alternatives. How the AM Plan will guide and adapt the implementation of actions through the decision space defined in this EIS; how decision criteria, thresholds, triggers and time frames will be used to initiate meaningful actions and/or subsequent regulatory requirements; and defining a clear commitment to change will be paramount to successfully achieving the objectives contained in the MRRMP-EIS.

The Service is looking forward to continuing to work collaboratively in support of this important effort to ensure the success and ultimate implementation of the MRRMP for the recovery of the fish and wildlife resources of the Missouri River, while also taking into consideration the human resources. Please contact me at (605) 665-4856 for further questions and clarification.

Sincerely yours,

RE: Interception Rearing Complex Targets

Dear Ms. Fitzner:

As a cooperating agency in the development of the U.S. Army Corps of Engineers' (Corps or USACE) draft Missouri River Recovery Management Plan and associated Environmental Impact Statement (MRRMP-EIS), the U.S. Fish and Wildlife Service (Service) provides the following *recommended targets for Interception and Rearing Complexes*. We provide these comments in partial completion of the draft Fiscal Year 2016 scope of work for the Service pursuant to the Fish and Wildlife Coordination Act (FWCA) of 1958, as amended (48 Stat. 401; 16 U.S.C. 661 et seq.), the National Environmental Policy Act (NEPA) of 1969 (42 U.S.C. 4321-4347), and pursuant to the Endangered Species Act (ESA) of 1973, as amended (87 Stat. 884; 16 U.S.C. 1531 et seq.).

This letter does not constitute the final report of the Secretary of the Interior as required by Section 2(b) of the FWCA for the MRRMP-EIS, nor does it constitute reconsultation of the 2000 and 2003 Amended Biological Opinion on the Operation of the Missouri River Main Stem Reservoir System, Operation and Maintenance of the Missouri River Bank Stabilization and Navigation Project (BSNP), and Operation of the Kansas River Reservoir System (BiOp) under section 7 of the ESA.

Interception Rearing Complex Targets in an Adaptive Management Context

The Service is providing the following recommendations to the Corps with regard to Interception Rearing Complexes (IRCs) Targets in an Adaptive Management context.

The Service supports the Adaptive Management process with regards to learning, modifying, and testing the IRC hypotheses and implementation of this habitat component. Our recommendations reflect a progression of implementation based upon learning and improving IRC's provided the hypotheses remains valid for the duration of the temporal scope of this EIS. Ultimately these efforts would lead to determination of a Level 4 implementation target within the temporal scope of the EIS.

These recommendations emanate from the June 2016 In Progress Review during which a request was made of the Service to provide recommendations on three components making up the level of implementation of IRCs:

- Study phase equivalent to 2 sites/year totaling 12 sites within 6 years
- Refurbishing existing Shallow Water Habitat sites
- Define additional IRC's needed to achieve the EIS objectives

These recommendations are intended as a step-wise progression of implementation for each of the above components within an Adaptive Management context.

While the functionality of IRC habitat has been only in part defined, we recognize that further refinement of IRC habitat will continue within the AM process. We recommend inclusion of the following to aid in computation of successfully implemented IRC habitats:

- I = Interception as a binary response, interception of particles (drifting larval pallid larvae) is or isn't occurring. In the future this component could be parsed out further based upon the relative rate of interception occurring.
- RC = Rearing Complex consisting of newly produced Food Producing and Foraging Habitat. Acre-days / year is the metric that will be utilized to define the amount of Rearing Complex habitat produced. Further discussion regarding the associated hypotheses can be found within the Missouri River *Scaphirynchus albus* (pallid sturgeon) effects analysis-Integrative Report 2016 - pages 112-120 (Jacobson *et al.* 2016). We anticipate improvements in determining the effectiveness of this metric in the near future.
- For computational purposes the amount of IRC's constructed in a given year will equal the sum of I(RC). We also recommend continuation of ongoing efforts to determine the biological significance of IRC's to the pallid sturgeon and refinement of a metric(s) measuring IRC's relationship to pallid sturgeon survival.

Flows play an important role in the function of IRC habitat and provide a means for producing IRC habitat. Although the Service is not requesting that flows be manipulated to implement IRC habitat during the study phase, the role of ambient flows should be included in all assessments should the need arise to utilize flows to help achieve IRC implementation targets in the future.

Following is a series of stages of IRC implementation recommendations:

Stage 1 – Begin study phase:

- Duration three years.
- At least two IRC sites constructed per year paired with control sites.
- Amount of functional IRC habitat added each year is equivalent or greater than 33,000 acre-days/year.
- Assess existing SWH habitat sites and determine potential for refurbishing as IRC sites.

Assessment:

- Assess IRC complexes.
- If results are positive or equivocal proceed to Stage 2 (decision criteria TBD).
- If hypotheses are no longer valid, discontinue efforts (decision criteria TBD).

Stage 2 – Continuation of study phase, refurbishing of SWH sites, and determination of level 3 implementation.

- Duration three years.
- At least two IRC sites constructed per year paired with control sites.

- Amount of functional IRC habitat added each year is equivalent to or greater than 33,000 acre-days/year.
- Refurbish SWH habitat sites in addition to study sites (rate TBD).

Assessment:

- Assess IRC complexes and refurbishment.
- If results are positive or equivocal proceed to Stage 3 (decision criteria TBD).
- If hypotheses are no longer valid, discontinue efforts (decision criteria TBD).

.Stage 3 – Level 3 implementation and determination of level 4 implementation.

- Duration four years.
- Continue assessing study sites and refurbished sites.
- Culminate refurbishing existing SWH sites as warranted.
- At least 66,000 acre-days/year of functional IRC habitat added each year. The ultimate rate of level 3 implementation needed to determine level 4 implementation rates within four years will be informed by Stages 1 & 2.

Assessment:

- If the hypotheses are no longer valid, discontinue efforts (decision criteria TBD).
- Based on results determine Level 4 IRC target and implementation rate.

Stage 4 – Level 4 implementation to ultimately remove paucity of IRC habitat as an issue to pallid sturgeon survival.

- Implement IRC habitats at level 4

The Service appreciates the opportunity to provide these recommendations to realize recovery of the listed species on the Missouri River. The Service is looking forward to continuing to work collaboratively in support of this important effort to ensure the success and ultimate implementation of the MRRMP for the recovery of the fish and wildlife resources of the Missouri River, while also taking into consideration the human resources. Please contact me at (605) 665-4856 for further questions and/or clarification.

Sincerely yours,

Casey D. Kruse

Fish and Wildlife Coordination Act Report for the Missouri River Recovery Management Plan and Science and Adaptive Management Plan

Introduction

The Fish and Wildlife Coordination Act (FWCA) provides a basic procedural framework for the orderly consideration of fish and wildlife conservation measures to be incorporated into Federal and federally permitted or licensed water development projects. The FWCA requires action agencies to consult with the U.S. Fish and Wildlife Service (Service) and the relevant state fish and wildlife agency or agencies whenever any department or agency of the United States or any public or private agency under Federal permit or license proposes or authorizes the waters of any stream or body of water in the United States to be impounded, diverted, channelized, controlled, or modified for any purpose whatever with a view to conservation of fish and wildlife resources.

The FWCA also requires that “wildlife conservation shall receive equal consideration with other project features” and “be coordinated with other features of water-resource development programs through the effectual and harmonious planning, development, maintenance, and coordination of wildlife conservation and rehabilitation ...” Section 2(b) of the FWCA requires reports and recommendations of the Service and state fish and wildlife agencies to be given full consideration and included in project reports to Congress or to any other relevant agency or person for authorization or approval.

This report constitutes the Service’s FWCA Section 2(b) report on the U.S. Army Corps of Engineers’ (Corps) proposed Missouri River Recovery Management Plan (MRRMP) and Science and Adaptive Management Plan (SAMP). This report will accompany the Final MRRMP/Final Environmental Impact Statement (FEIS) when published.

Habitat conservation and restoration are fundamental to achieving the Service’s mission to conserve, protect and enhance fish, wildlife, and plants and their habitats for the continuing benefit of the American people. Delivering sustainable conservation must rely on concerted efforts with all our partners, using their full suite of authorities and opportunities, to recognize, quantify, and enhance the value of fish and wildlife for people. The Service works with others to mitigate losses of fish, wildlife, and their habitats, and uses thereof from land and water developments using our Mitigation Policy (Federal Register, Vol. 46, No. 15, January 23, 1981 as corrected February 4, 1981). Our mitigation policy is established in accordance with the Fish and Wildlife Act of 1956 (16 U.S.C. 742(a)-754) and (16 U.S.C. 661 – 667 (e)), the Watershed Protection and Flood Prevention Act (16 U.S.C. 1001 - 1009), and the National Environmental Policy Act (42 U.S.C. 4321 – 4347).

The purpose of the MRRMP as described in that document is “to develop a suite of actions that meets Endangered Species Act (ESA) responsibilities for the endangered pallid sturgeon (*Scaphirhynchus albus*) and interior population of the least tern (*Sternula antillarum*), and the threatened Northern Great Plains population of the piping plover (*Charadrius melodus*). Authorities used to meet this purpose may include existing Corps authorities related to Missouri River System operations for listed species and acquisition and development of land needed for creation of habitat for listed species provided by Section 601(a) of Water Resource Development Act (WRDA) 1986, as modified by Section 334(a) of WRDA 1999, and further modified by

Section 3176 of WRDA 2007, although alternatives formulation was not limited to these authorities.” The Draft Environmental Impact Statement was clear that the proposed management actions are intended to provide benefits to least terns, piping plovers and pallid sturgeon and we believe those actions may also provide benefits to other native species.

To reflect the intent to meet ESA responsibilities, the MRRMP/EIS also had the following Fundamental Objectives:

- Avoid jeopardizing the continued existence of the threatened Northern Great Plains population of the piping plover due to the U.S. Army Corps of Engineers actions on the Missouri River.
- Avoid jeopardizing the continued existence of the endangered Interior Least Tern due to the U.S. Army Corps of Engineers actions on the Missouri River.
- Avoid jeopardizing the continued existence of the pallid sturgeon due to the USACE actions on the Missouri River.

The Service anticipates, in collaboration with the MRRP, that regular evaluation of new available information obtained from monitoring and research will be undertaken, and that pertinent findings will be utilized to update the models used, adapt and refine the management actions, objectives, sub-objectives, metrics, and targets.

The purpose of this report is to identify and evaluate fish and wildlife resource concerns, opportunities, and specific recommendations for the MRRMP and SAMP to ensure fish and wildlife resources receive equal consideration with other project purposes. This report includes (1) background information for this document, (2) identification of problems or issues and opportunities regarding fish and wildlife resources, (3) planning objectives within the MRRMP planning area, (4) an impact analysis of the Corps’ planning alternatives, (5) recommendations on conservation and mitigation measures, and (6) the Service’s position regarding the MRRMP. This report is based on several planning aid letters and memorandums previously submitted to the Corps regarding the fish and wildlife issues within the project area (Appendix A), and information received from the Corps staff, Service field staff, state biologists, and species experts. The Service also considered the most recent studies and monitoring data; assumptions and uncertainties on the relationships between the populations and environmental conditions; and management actions, especially flow management and mechanical habitat creation to develop this document.

Pursuant to the FWCA, the Service coordinated development of this document with the state fish and wildlife agencies of Montana Fish, Wildlife and Parks; North Dakota Game and Fish Department; South Dakota Department of Game, Fish, and Parks; Nebraska Game and Parks Commission; Iowa Department of Natural Resources; Kansas Department of Wildlife, Parks and Tourism; and Missouri Department of Conservation. Comments received from these State Fish and Wildlife Agencies have been incorporated into this report.

Background Information

Historically, the Missouri River was a diverse, unaltered, 2,341 mile-long dynamic riverine/floodplain ecosystem of braided channels, cottonwood stands, chutes, sloughs, islands, sandbars, backwater areas, mudflats, deep pools, and natural floodplain communities. These

riverine and floodplain habitats were maintained by a dynamic equilibrium of continuous bank erosion and deposition, which constantly reshaped the channel and floodplain. The river carried a high sediment load, thus earning the nickname "Big Muddy," and had a high propensity for flooding and changing the locations of its channel. Typical river flows rose throughout the spring and peaked in late June, then declined throughout the summer and fall reaching their low point in late December. In the lowermost reach in Missouri, a slight rise occurred in October/November from fall rains. This variety of habitats supported numerous wildlife species that together made up a healthy ecosystem.

Many of the habitats, while still in existence today, are greatly reduced in size, are fragmented across the landscape and are functionally disconnected from the river's hydrology. Fish and wildlife values associated with the "natural" Missouri River ecosystem were significantly altered by construction and operation programs of the Pick/Sloan Plan (1944 Flood Control Act) and the Missouri River Bank Stabilization and Navigation Project (BSNP). These programs, administered by the Corps and the Bureau of Reclamation, transformed the free-flowing natural river into a system of seven main stem reservoirs and highly altered riverine reaches influenced by regulated flows, self-channelization, and bank stabilization. In addition to the main stem modifications, the river is influenced by: a) extensive reservoir development in the large tributary basins of the Platte, Kansas, and Osage Rivers; b) channelization of floodplain tributaries; and c) extensive levees along the lower Missouri River (hereafter river) and major tributaries.

Section 2(g) of the FWCA requires any project that controls, modifies or diverts water, or any unit of such project authorized before August 12, 1958, the date of enactment of the FWCA, that was less than 60 percent complete at the time the Act was passed, was subject to the provisions of the Act. The Corps determined at that time that the BSNP below Sioux City was 58 percent complete on the day the Act was signed into law; therefore the BSNP was subject to the FWCA. The Corps commenced work to complete a plan that recommended mitigation measures to offset some of the adverse impacts to fish and wildlife habitat caused by the BSNP.

Roughly 168,000 acres of natural channel and 354,000 acres of meander belt habitat have been lost from the lower 735 miles of the river (Table 1). The BSNP alone reduced shallow water habitat (0-5 foot depths) by up to 90 percent in some river reaches, eliminated 50 percent of the river's surface area, virtually eliminated sandbars and islands, and resulted in the conversion of nearly 67,000 acres of riverine habitat into, primarily, privately owned and leveed agricultural land. Floodplain forest was reduced from 76 percent of floodplain vegetation in the 19th century to 13 percent by 1972.

Table 1. USACE-Estimated Habitat Losses due to BSNP, 1912-2003

State	River Channel	Meander Belt		Total
	Aquatic	Terrestrial	Terrestrial	acres
Missouri	55,900	27,700	221,400	305,000
Iowa	17,100	18,700	29,600	65,400
Kansas	9,100	2,000	44,000	55,100
Nebraska	18,200	19,400	59,000	96,600
Total	100,300	67,800	354,000	522,100

While the lower river was being modified for navigation, over one third of the river's total length was inundated by reservoirs in the upper basin, converting free-flowing river, bottomland timber, marshes, grasslands, and sandbars to deep water. Although some sections of the river does not fall under the provisions of the FWCA, in Nebraska and South Dakota alone, 117,000 acres of timber, 84,000 acres of river, and 10,000 acres of sandbar were lost. Flows have been modified primarily to meet flood control, navigation, and hydropower objectives. Consequently, the normal flow pattern has been significantly altered, with spring high flows suppressed drastically and low summer and fall flows increased. Downstream of Kansas City, the effect of the dams on flows is moderated by large tributary inflows.

The Service and our state fish and wildlife conservation partners have worked with the Corps over the last 70 years to improve and conserve fish and wildlife resources in and along the Missouri River to benefit the public and ensure those resources receive equal consideration with the other project purposes in development of the Corps Missouri River System (i.e., construction and operation of the Main Stem reservoirs) as well as the 750-mile BSNP.

The Service and state agencies have provided ongoing fish and wildlife recommendations throughout that time, including planning input during the BSNP Fish and Wildlife Mitigation Project (Mitigation Project), Missouri River Master Manual (MRMM) revisions and associated Biological Opinions under the ESA, as well as regular coordination during project implementation. The BSNP Mitigation Project was authorized in Section 601(a) of the 1986 WRDA and modified by Section 334(a) of WRDA 1999 to acquire and develop lands to mitigate for lost habitats due to the BSNP.

The Service has issued Biological Opinions in 1990, 2000, 2003 and 2018 under the ESA addressing Corps operations of the Missouri River system, (i.e., Missouri River Main Stem System, operation and maintenance of the BSNP, and operation of the Kansas River Reservoir System). The Service determined that Corps operation of the system was likely to jeopardize the continued existence of the endangered interior least tern, and the threatened Northern Great Plains piping plover in 1990 and 2000, and the endangered pallid sturgeon in 2000 and 2003. To offset those effects, the Biological Opinion (BiOp) directed the Corps to restore a portion of the historic habitat and hydrological functions/processes of the river. In the short-term, pallid sturgeon population augmentation and research would complement ongoing habitat acquisition, restoration, and monitoring, within an adaptive management framework. The 2018 BiOp determined that the Proposed Action will stabilize or improve the population abundance, and increase survival of the pallid sturgeon, piping plover, and interior least tern through implementation of the Science and Adaptive Management Plan, conservation measures, and the Section 7(a)(1) plan. The 2018 BiOp conclusion is that the Proposed Action will not jeopardize the continued existence of the pallid sturgeon, piping plover, and interior least tern and will not destroy or adversely modify designated critical habitat for the piping plover.

The 2007 WRDA (SEC. 3176) expanded the Corps authority to use the funds made available for recovery or mitigation activities in the lower basin of the Missouri River for recovery or mitigation activities in the upper basin of the Missouri River, including the States of Montana, Nebraska, North Dakota, and South Dakota. Most recently, the Corps combined the BSNP

Mitigation Project with activities to comply with the ESA to become the Missouri River Recovery Program (MRRP).

The MRRMP-EIS is an effort to incorporate new scientific information into management actions for pallid sturgeon, least terns, and piping plovers and to develop an Adaptive Management Plan. The current effort is to “to develop a suite of actions that meets Endangered Species Act (ESA) responsibilities for the endangered pallid sturgeon (*Scaphirhynchus albus*) and interior population of the least tern (*Sternula antillarum*), and the threatened Northern Great Plains population of the piping plover (*Charadrius melodus*).” The MRRMP planning process provides an opportunity for the Corps to objectively assess recent scientific findings regarding Corps Missouri River management effects on federally listed species, their habitats and ecosystem processes to determine a sustainable path forward through analysis of a robust and comprehensive range of actions and alternatives. The Service considers this effort an important component of the adaptive management approach to implementing fish and wildlife conservation on the river and believes many of the actions undertaken on behalf of the identified listed species will also provide some benefits to other fish and wildlife species along the Missouri River.

Description of the Project Area and Fish and Wildlife Resources

The Missouri River basin encompasses 530,000 square miles—approximately one-sixth of the continental United States. The Missouri River flows 2,341 miles from its headwaters in southwestern Montana to its confluence with the Mississippi River near St. Louis. One-third of the Missouri River is impounded by dams/reservoirs; one-third is channelized/stabilized; and one-third is free-flowing but regulated by Corps’ operations. The Corps’ MRMM prescribes operation of system storage and release for the multiple project purposes of flood control, irrigation, downstream municipal and industrial water supply and water quality, navigation, hydropower production, recreation, and fish and wildlife.

Although anthropogenic changes have altered many of these natural processes, important habitats still remain for Federal trust species and a variety of other wildlife: at least 300 species of birds, 150 species of fish, 60 species of mammals, and 50 species of reptiles and amphibians. The dynamic nature of the Missouri River means that habitats change on a daily, seasonal, annual, and long-term basis. Erosive forces constantly transport sediment down the river, creating and modifying habitat and removing terrestrial vegetation from some areas while creating suitable conditions for new plants to grow in other areas. Seasonal river flow patterns flood river-bottom wetlands and maintain lakes in the floodplain that provide important wildlife breeding and foraging habitat. The combination of open water, floodplain wetlands, and riparian vegetation is particularly important for the large number of migratory birds that use the Missouri River during spring and fall migrations.

The following is a list of fish and wildlife habitats that can be found in and along the Missouri River (Copied from Gagnon, et al. 2013 Unpublished Paper).

1. **Thalweg/Mid-channel:** This habitat includes the line of maximum depth and velocity in the river channel as well as the area of channel from the edge of the thalweg to the edge of the channel border on both sides. It supports flow, sediment transport, longitudinal connectivity, and vertical water movement in the river system. Included in this habitat are channel crossovers that connect habitat on one bank to the opposite bank and provide

habitat for many fish and invertebrate species. Bedform topography and contour, depth, velocity, substrate, and sediment regime vary throughout this area.

2. **Riverbank/Cut Bank:** Riverbank habitats are the shifting channel margins containing diverse and dynamic microhabitats with varying slopes, vegetation types, shading, woody debris, and sediments. The riverbank/cut bank is a major source of sediment to the river system due to erosion and deposition processes as well as avulsion and meandering. Where rocky outcrops form the riverbank, boulders, cobbles, and gravels form the underlying river bed, although this is a relatively uncommon substrate type throughout most of the river which typically has a sandy bed. Riverbank/cut bank habitat may include small pools along the bank, which are fed by hyporheic flow. The riverbank/cut bank is utilized as refuge, nesting, and forage habitat by numerous species.
3. **Channel Margin:** The channel margin is the shallow water habitat between the floodplain and the thalweg/midchannel. This area generally is a low-energy and low-velocity habitat.
4. **Secondary Channel:** Secondary channel habitats including chutes and side channels are connected by surface flows to the main channel and typically contain less flow and reduced velocity and depth compared to the mainstem channel. Most secondary channels are connected at the upstream and downstream ends, although some exhibit this connectivity only during high flows.
5. **Pool:** Pools are generally areas of slower velocity and greater depth within the river channel. They are dynamic in nature and are formed and actively altered by erosion and scour. Frequently they occur at river bends, downstream of in-stream sandbars, woody debris jams, or other in-stream obstructions (Keller and Swanson 1979; Abbe and Montgomery 1996; Galat et al. 2001). Pools provide overwintering habitat for fish (Berry and Young 2001).
6. **Sandbar:** A bar is a raised deposition of sand, gravel, or cobble generated by hydrological processes in the river. Bars are found within the channel and along the channel margins and include wet or dry and vegetated or unvegetated types. Bar habitats vary in relation to hydrologic regime, presence or absence of large wood, vegetation structure, temporal and spatial distribution, and topography. The water table in this habitat type is variable and flows may be slow or have zero velocity. The bar and associated shallow water habitat is dynamic, either aggrading or degrading as sediment is deposited or eroded. Sediment movement is determined by flow and grain size. During low flow, sand, gravel, cobble, or other sediment stops and settles, whereas during high flow, habitats are created and exposed. A wide range of species utilize this habitat, including birds, amphibians, reptiles, fish, and shellfish.
7. **Island (habitats overlap with floodplain ecosystems):** Islands are areas of elevated substrate within the channel that contain well developed vegetative structure. Islands form either from flood deposited sediment that has developed more permanent vegetation or through the isolation of floodplain fragments from avulsion (Hesse 1996). Some islands may have formed from substrate deposition around large snag piles. Vegetation is diverse, and varies depending on the stability of the reach. It may consist of woody vegetation, savanna, or multiple succession stages, although the common woody species of this habitat is the cottonwood. Inundation is infrequent due to higher elevations; however, islands can contribute organic matter to the river system when flooding occurs (Hesse et al. 1988). Islands split the waterbody channel, thereby creating a more varied habitat.
8. **Floodplain (habitats overlap with floodplain ecosystems):** The floodplain consists of

lands adjacent to the river channel. The elevation of the floodplain generally occurs at about the stage of the mean annual flood. Through natural riverine processes of flooding, erosion, and deposition, the floodplain contributes nutrients, sediments, and large wood to the river system (Ward and Stanford 1995). During high-flow events, floodwaters erode and deposit alluvial features throughout the floodplain, dissipating energy from the flood pulse. After the flood pulse recedes, the floodplain does not remain uniformly wet.

9. **Fringe Wetland/ Vegetated Mudflat:** Fringe areas consist of wetlands and vegetated mudflats along areas of flow. They provide a link between the channel and mudflats or backwaters. Fringe areas are a transitional state of mudflats. This habitat is characterized by low flow and low sediment inputs although when sedimentation occurs, it is fine sized and high in organic content. Fringe habitat provides a refuge for young of the year fish and juvenile turtles as currents are slow and predators are less abundant.
10. **Oxbow Basin:** Oxbows are formed by channel migration and cutoff, leaving an open water area isolated from the main channel except during high-flow events. Hydrologic connectivity is provided by groundwater or overland inundation. Water levels are deep; however, they become shallower as they fill with sediment and organic debris, eventually transitioning into emergent marshes.
11. **Backwater:** Backwaters consist of shallow low-flow lakes and wetlands connected by surface water to the main channel at the downstream end. Backwaters are unstable and form during flooding events, following subsidence and compaction of floodplain soils, or develop from channel migration and infilling. Flow occurs on a seasonal cycle and depends on inundation from the main channel but is generally very low or lacking for most of the year. Backwaters are generally warm, high in organic matter, and potentially low in dissolved oxygen (Eckblad et al. 1984; Bayley 1995; Sargent and Galat 2002) at some times of the year.
12. **Unvegetated Mudflat:** The primary characteristics of unvegetated mudflats are a lack of vegetation and fine sediment size (silt or clay). Flow is low and the water table fluctuates, often causing the formation of ephemeral pools. Organic matter content is high.
13. **Emergent Wetland/ Marsh:** Emergent areas are found as part of mudflats, oxbows, and backwater lakes. They are dominated by macrophytes, such as broad-leaved cattails and phytoplankton such as diatoms. This habitat experiences frequent disturbance from flooding, scouring, herbivory, trampling, and fire (LANDFIRE 2009). Sediment is transported to and from the habitat with flood events.
14. **Open-water Wetland Depression (habitats overlap with floodplain ecosystems):** Relatively shallow, undrained depressions with year-round open water and without surface water connection except during flood flows. These habitats include sloughs and lentic areas of various shapes and sizes. Many of these habitats have formed in former primary or secondary river channels. It is connected to the main channel during high-flow events (Knowlton and Jones 1997).

The significant degradation and alterations to the key physical drivers of the Missouri River ecosystem (river flows, sediment transport, river habitat quality, and river-floodplain connectivity) have cascading and compounding effects on each other and on other important physical conditions (water chemistry and temperature, river-floodplain habitat turnover, river habitat size and connectivity, and floodplain habitat quality); and the effects of all these alterations on the ecosystem-scale biotic conditions that depend on them (river food web, native river wildlife, native floodplain wildlife, native river and floodplain vegetation) (Table 2). The

severely degraded and altered key physical drivers of the Missouri River ecosystem have had severe ecosystem-scale biological effects. The riverine alterations also combine with alterations affecting the river and floodplain systems together (e.g., altered river-floodplain connectivity), and alterations affecting the floodplain ecosystem alone (e.g., conversion of floodplain habitat to intensive land uses), to produce even greater biological alteration to the Missouri River floodplain ecosystem.

Many of the natural habitats remaining in the project area occur in or adjacent to public lands managed for conservation. The Department of Interior (DOI) and each state along the river manage portfolios of conservation lands for the benefit and enjoyment of the public. These public lands include some of the best remaining habitats in the project area, and provide ecological services, economic benefits and environmental education and enjoyment to millions of people.

Currently, the BSNP Mitigation Project has acquired, protected or restored fish and wildlife habitat on over 71,000 acres of land along the Missouri River, from South Dakota through Missouri. Many of these areas provide important aquatic habitats that were lost through construction of the channel. Other state and Federal conservation land form a critical network of habitats that vary seasonally and annually to support hundreds of species. The intersection of land and water is fundamental to the ecological functions these lands provide. Connecting larger blocks of habitat allows species to move throughout the river and floodplain to meet their life requirements. Hydrologic connectivity is equally as important as spatial connectivity, especially to allow aquatic organisms to access temperature or velocity refugia, important nursery and forage areas, and high quality spawning habitats. Much of the floodplain that is connected to the river can be found on these conservation lands. River management that accounts for continued change in climate, channel morphology, and hydrologic patterns is critically important to ensure these lands continue to support fish and wildlife in the future.

Table 2. Key Missouri River Physical Drivers, Physical Conditions and Biotic Conditions

Physical Drivers	River Flows	The flow regime of a river, including the natural pattern of inter- and inter-annual variation in flows, and extreme events to which native species have adapted.
	River Sediment	The amount, size, and types of substrates carried by the river that form river and floodplain habitats and shape the organisms occupying them.
	River Habitat Quality	The natural environments in the river channel where organisms live, feed, grow and reproduce, including main channel, side channels, backwaters, pools, and channel margins.
	River-Floodplain Connectivity	The ability of the river to spread out of the channel across the floodplain, providing life requisites of numerous aquatic and floodplain species; nutrient dispersion and exchange; and creation, maintenance and redistribution of habitats.
Physical Conditions	River Water Chemistry	The dissolved and suspended components of water that strongly shape the presence, health, and survival of organisms.
	River Water Temperature	The thermal conditions that seasonally affect river morphology (e.g., ice dams), and strongly affect organismal growth, development, metabolism, and the timing of migration, spawning and hibernation.
	River-Floodplain Habitat Turnover	The ability of the river to naturally shift laterally and longitudinally across the floodplain, forming and reworking banks, meanders, sandbars, and other habitats.
	River Habitat Size & Connectivity	The amount of mainstem channel and side-channel habitat, and the extent to which mainstem and lower reaches of large tributaries are barrier-free, and allow the up- and downstream movements of aquatic species and transported matter.
	Floodplain Habitat Quality	The natural environments in the floodplain where organisms live, feed, breed, and raise their young, including marshes, wetlands, oxbow lakes, forests, prairies, and shrublands.
	Floodplain Habitat Size & Connectivity	The amount of natural habitats on the floodplain and the extent to which barrier-free movement of native organisms and materials can occur.
Biotic Conditions	River Food Web	The production, storage, consumption, and movement of energy and food resources through all trophic levels in the river system.
	Native River Wildlife	Composition, diversity, and abundance of native riverine faunal assemblages.
	Native Floodplain Wildlife	The native fauna that reside in the floodplain and depend on it for activities such as feeding, nesting, rearing young, and hibernating.
	Native River and Floodplain Vegetation	Native plant communities of the river, channel margin, and floodplain, including marshes, forests, shrubs, wetlands, tallgrass and shortgrass prairies.

Other Federally Listed and At Risk Species

The major focus of this Corps planning effort is avoiding jeopardy to three federally listed species: the pallid sturgeon, the Interior least tern and the piping plover. The EIS, associated documents, and many of the Service's documents listed above provide detailed information on current status, species needs, and recovery actions to support their conservation. This section will focus on several other federally listed or at risk species that occur in and along the Missouri

River system that would benefit from appropriate restoration activities and mitigation lands. The Corps has developed a Section 7(a)(1) Conservation Plan that would be implemented complementary to the other actions identified in the MRRMP (USACE 2017, Appendix D). This plan includes a conservation strategy to avoid adverse impacts to gray bat, Indiana bat, and northern long-eared bat.

Indiana bat (*Myotis sodalis*), federally listed endangered – From late fall through winter Indiana bats in Missouri hibernate in caves in the Ozarks and Ozark Border Natural Divisions. During the spring and summer, Indiana bats utilize living, injured (e.g., split trunks and broken limbs from lightning strikes or wind), dead or dying trees for roosting throughout the Missouri River system. Indiana bat roost trees tend to be greater than 9 inches diameter at breast height (dbh) (optimally greater than 20 inches dbh) with loose or exfoliating bark. Most important are structural characteristics that provide adequate space for bats to roost. Preferred roost sites are located in forest openings, at the forest edge, or where the overstory canopy allows some sunlight exposure to the roost tree, which is usually within 1 km (0.6 mi.) of water. Indiana bats forage for flying insects (particularly moths) in and around the tree canopy of floodplain, riparian, and upland forests.

Northern long-eared bat (*Myotis septentrionalis*), federally listed threatened - The Northern long-eared bat occurs throughout Missouri and Iowa, and similar to the Indiana bat, roosts in caves (or habitats similar to caves) during the winter and under loose tree bark or in tree cracks or crevices during the summer. The northern long-eared bat can also be found in forested habitats in Kansas, eastern Montana, Nebraska, North Dakota and South Dakota.

Gray bat (*Myotis grisescens*), federally listed endangered - The gray bat occupies a limited geographic range in limestone karst areas of the southeastern United States, including Kansas and Missouri. With rare exception, the gray bat roosts in caves year-round. In winter, most gray bats hibernate in vertical (pit) caves with cool, stable temperatures below 10 degrees Celsius. Summer caves, especially those used by maternity colonies, are nearly always located within a kilometer (0.6 mile) of rivers or reservoirs over which bats feed. The summer caves are warm with dome ceilings that trap body heat. Most gray bats migrate seasonally between hibernation and maternity caves, and both types of caves are located in Missouri. Gray bats are active at night, foraging for insects over water or along shorelines, and they need a corridor of forest riparian cover between roosting caves and foraging areas. They can travel as far as 20 kilometers (12 miles) from their roost caves to forage.

The greatest current threat to all three species of bats is White-nose syndrome (WNS). WNS is named for the white fungus that appears on the muzzle and other parts of infected hibernating bats. WNS is associated with extensive mortality of bats in eastern North America and has spread rapidly across the eastern United States and Canada. The fungus that causes WNS has been detected as far south as Mississippi and as far west as the state of Washington. Bats with WNS act strangely during cold winter months, including flying outside in the day and clustering near the entrances of hibernacula (caves and mines where bats hibernate). Bats have been found sick and dying in unprecedented numbers in and around caves and mines. WNS has killed more than an estimated 5.7 million bats in eastern North America. In some hibernacula, 90 to 100 percent of bats have died.

The project area contains suitable habitat for all three bat species. In fact, areas in and along the Missouri River floodplain support maternity and winter bat hibernacula, potential swarming

habitat, and maternity colonies. Continued habitat protection, acquisition, and restoration are important in helping these species contend with other environmental threats, and can provide meaningful benefits towards recovery. While gray and Indiana bats occur only in the Missouri portion of the study area, the Northern-long eared bat occurs throughout the basin. Recent anecdotal sampling information in the lower basin has failed to detect this species in many areas where it has occurred just a few years previous¹. Because data indicate Northern long-eared bats are short distance migrants, it is likely that Northern long-eared bats using the Missouri River Floodplain in the summer may have winter hibernacula nearby. Thus protecting and restoring habitats to support this species can be especially important in aiding the species recovery.

Sicklefin and Sturgeon Chub (*Macrhybopsis meeki* and *Macrhybopsis gelida*) recently petitioned for listing -The sicklefin and sturgeon chub are members of the Cyprinidae, or minnow family. They are native to the Missouri River basin and the Mississippi River downstream from the confluence with the Missouri River. Both species are highly adapted for conditions found in large free-flowing rivers with relatively high levels of turbidity. They are considered to be an extremely important forage base for the federally endangered pallid sturgeon.

The sicklefin chub is usually yellowish or tan colored on the back and silvery-white on the belly with a snout protruding slightly beyond the mouth. The sicklefin chub can be most readily distinguished by its elongated pectoral fins and a sickle-shaped dorsal fin. The sturgeon chub is tan to pale green on the back and cream to white on the belly. A few black speckles occasionally are present on the sides and back. Sturgeon chub can be identified by the unique longitudinally-arranged ridges or keels on most scales. Both chub species are relatively short-lived with a maximum life-span of about 4 years.

The sicklefin chub was historically found in the Lower Yellowstone River, Missouri River and Mississippi River downstream from the confluence with the Missouri River. Sturgeon chubs have been collected at or near the same locations where sicklefin chub populations have been documented in the Yellowstone, Missouri, and Mississippi Rivers. They also ascend farther upstream in the Yellowstone and Missouri Rivers and larger tributaries of these rivers than the sicklefin chub.

In 2001, the Service issued a not warranted 12-month finding in response to a petition to list both species (USFWS 2001). In that finding, the Service noted that updated information indicated self-sustaining populations of sicklefin chub occur in three locations within the Missouri River basin: above the headwaters of Fort Peck Reservoir in Montana; in the Yellowstone-Missouri River confluence area of Montana and North Dakota; and in the Missouri River from St. Joseph, Missouri to the confluence with the Mississippi River. Missouri Department of Conservation data since 1997 indicated a viable population of sicklefin chub is present in the Middle Mississippi River and in the Wolf Island area of the Lower Mississippi River. The Service estimated sicklefin chub populations occupied approximately 54 percent of its historic range in the Missouri River basin at that time. Viable populations of sturgeon chub were found at or near the same locations where sicklefin chub populations were documented. In addition, sturgeon chub populations were present in 11 of the 30 tributaries to the Yellowstone and Missouri Rivers where they were historically collected. Sturgeon chub populations currently occupy about 1,155 miles or about 55 percent of its former range in the Missouri River.

¹ Personal Comm. Jane Ledwin, USFWS, Columbia, MO.

In August 2016, WildEarth Guardians petitioned the Service to list both species. The Service completed a positive 90-day finding for the sicklefin and sturgeon chubs on December 20, 2017 (USFWS 2017). Species Status Assessments for both chub species will be undertaken prior to completion of the 12-month finding. The petitioners cite more recent data that they believe indicate fewer occurrences within their ranges; extirpation from previous occupied river reaches; and continuing population declines. They attribute those patterns to continued habitat degradation and fragmentation, water depletions, pollution, predation, isolated populations and delays in proposed restoration projects.

Habitat degradation and fragmentation through construction of the mainstem dams and navigations channel has significantly affected these chub species. At the same time, given the habitats preferred by the chubs and their short reproductive cycles, they could serve as excellent surrogates to monitor the success of aquatic restoration for the native benthic fish community, as well as an important prey item for pallid sturgeon. In fact, previous monitoring on the river documented short-term, positive chub responses to chute construction with the appropriate seasonal water levels. Chubs that had not been documented for a number of years were found in surprising abundance in some chutes following high water events/years.

Monarch Butterfly (*Danaus plexippus plexippus*) petitioned species - The Service is undertaking a 12-month finding for this species that should be completed in fiscal year 2019. The project lies within the range of the monarch butterfly and the Service has determined that listing under the ESA may be warranted for the monarch and is currently conducting a status review of the species. Monarch butterflies are found throughout the Missouri River basin and some populations migrate vast distances across multiple generations each year. Many monarchs fly between the U.S., Mexico and Canada – a journey of over 3,000 miles. This journey has become more perilous because of increasing threats along their migratory path as well as impacts to their breeding and wintering grounds. Monarch populations have declined over 90 percent during the last 20 years. Primary threats to the species are attributed to loss of milkweeds and increased use of pesticides. Missouri River conservation lands provide important opportunities to restore suitable, sustainable monarch habitat, while also supporting numerous other wildlife species.

Fish and Wildlife Resource Concerns and Opportunities

The Service recognizes that fish and wildlife conservation is based not only on protection and conservation of individual species, but also on protection, enhancement and/or restoration of those habitats and associated physical drivers and conditions discussed above upon which they depend for survival. The problems facing the Missouri River fish and wildlife resources are, for the most part, a consequence of decades of river engineering and altered ecological processes, (physical drivers and conditions) that continue to further degrade the natural form and functions of the river, as well as threaten ecosystem-scale biotic conditions, communities and infrastructure. The lower Missouri River has undergone considerable change due to dam construction, channelization, altered flow regimes and floodplain development. The result has been a greatly reduced river corridor, with a commensurate decrease in habitat for fish and wildlife. In fact, the river continues to change. The dams and bank armoring interrupt the natural processes of sediment erosion, downstream sediment transport and deposition. This has already led to an almost complete loss of islands and sandbars in the lower river, and continues to cause bed degradation throughout the main channel as well as impact the tributaries causing bank erosion and head-cutting. Bank stabilization and channelization of the Missouri River, part

of the BSNP, have resulted in floodplain wetlands being disconnected from the underlying groundwater. Continued entrenchment of the river threatens not only fish and wildlife habitats, but the communities and residents along the river. Mitigation measures that help restore more natural physical drivers and conditions of the river, including the sediment dynamics, can serve to arrest this destructive and expensive trend. The MRRMP/EIS will incorporate new scientific information into management actions for the pallid sturgeon, least tern, and piping plover and develop an Adaptive Management Plan with objectives to benefit those species. It is anticipated that scientific information gleaned from the MRRMP will have some crossover benefits to fish and wildlife resources that may prove helpful in offsetting impacts to resources that have been heavily impacted by the extensive changes that have occurred on the Missouri River.

Climate Change

Climate change will be the overarching issue for fish and wildlife conservation in future decades. Changes in temperature and precipitation are expected to affect the northern Great Plains region and, consequently, the Missouri River Basin.

Over the last few decades, average temperatures have risen throughout the Great Plains, with the largest increases occurring in the winter months and over the northern states. Relatively cold days are becoming less frequent and relatively hot days more frequent. The temperature in the Great Plains has already increased ~1.5°F relative to the 1960–1979 baseline established by the U.S. Global Change Research Program. By late this century, it is projected to increase by anywhere from 2.5°F to more than 13°F compared with the 1960–1979 baseline, depending on future emissions of heat-trapping gases. The brackets on the thermometers represent the likely range of model projections, though lower or higher outcomes are possible (globalchange.gov). In the future, temperatures are projected to continue to increase commensurate with the levels of emissions of heat-trapping gases. Summer increases are projected to be greater than those in winter in the southern and central Great Plains. Temperatures in the Great Plains are projected to increase significantly by the end of this century, with the northern part of the region experiencing the greatest projected increase in temperature (globalchange.gov).

Precipitation is also expected to change, particularly in winter and spring. Conditions are expected to become wetter in the north and drier in the south. Projected changes include more frequent extreme events such as heat waves, droughts, and heavy rainfall. The Great Plains currently experiences a sharp precipitation gradient from east to west, from more than 50 inches of precipitation per year in eastern Oklahoma and Texas to less than 10 inches in some of the western parts of the region. Northern areas of the Great Plains are projected to experience a wetter climate by the end of this century, while southern areas are projected to experience a drier climate compared to the 1960–1979 baseline.

Climate change is likely to combine with other human-induced stresses to further increase the vulnerability of ecosystems to pests, invasive species, and loss of native species. Breeding patterns, water and food supply, and habitat availability will all be affected by climate change.

Grassland and plains birds, already stressed by habitat fragmentation, could experience significant shifts and reductions in their ranges. In addition, changes in precipitation coupled with shifts in temperature are likely to place additional stress on water resources in the project area. Although the project area is predicted to become warmer and wetter, these changes may

result in shifts in types of precipitation—for example, less snowfall and more rainfall, earlier snowmelt, earlier peak streamflow, or shifts in timing of flows in the Missouri River.

Changes in precipitation and temperature associated with climate change will directly affect fish and wildlife resources in the project area. In addition, as discussed above, the Missouri River is a highly regulated system. The shift of human populations from rural to urban areas will increase the demand on surface water resources, including the Missouri River. Such increased demand coupled with decreased groundwater supplies will result in greater pressure on Missouri River water for municipal and industrial uses, further affecting fish and wildlife populations. Climate change–induced shifts in temperature and precipitation, especially in the lower part of the Missouri River basin, may result in the need for new operating procedures for the main stem reservoirs; and these changes could further affect fish and wildlife communities in the project area.

Invasive and Injurious Species

Under the Lacey Act (18 U.S.C. 42), the Secretary of the DOI is authorized to regulate the importation and transport of species, including offspring and eggs, determined to be injurious to the health and welfare of humans, the interests of agriculture, horticulture or forestry, and the welfare and survival of wildlife resources of the United States. Under the terms of the injurious wildlife provisions of the Lacey Act, the Service maintains a list of injurious wildlife species. Species are added to the list of injurious wildlife to prevent their introduction or establishment through human movement in the United States to protect the health and welfare of humans, the interests of agriculture, horticulture or forestry, and the welfare and survival of wildlife resources from potential and actual negative impacts. Injurious wildlife are mammals, birds, amphibians, reptiles, fish, crustaceans, mollusks and their offspring or gametes that are injurious to the interests of human beings, agriculture, horticulture, forestry, wildlife or wildlife resources of the United States. The following species are determined to be injurious wildlife and are a concern for the ecological health of the Missouri River.

Asian Carp

“Asian carp” typically refer to four species of carp native to Asia: black carp (*Mylopharyngodon piceus*), bighead carp (*Hypophthalmichthys nobilis*), grass carp (*Ctenopharyngodon idella*), and silver carp (*Hypophthalmichthys molitrix*). Invasive bighead and silver carp, collectively referred to as bigheaded carps, are established in the Missouri River downstream of Gavins Point Dam. Their range expands into Missouri River Basin states via tributaries, including the James River in the Dakotas, the Platte River in Nebraska, the Kansas River in Kansas, the Grand River in Missouri, and other connected tributaries of the Lower Missouri River. Impacts of these invasive fish on our native aquatic resources in the Missouri River are largely unknown. However, literature indicates that crustacean zooplankton usually suffer population declines of 50 to 90 percent when silver carp and bighead Carp are introduced. Limited data from the Lower Missouri River are consistent with that trend. Condition of gizzard shad (*Dorosoma cepedianum*), a native planktivore, has declined in the Lower Missouri and Illinois Rivers since the bigheaded carp invasion. Impacts to native species are of utmost concern as well as developing a control strategy for the bigheaded carps in the Missouri River Basin. Large dams such as Gavins Point create a physical barrier to the expansion of these species. However, concerns remain about expansion by accidental or deliberate introduction. Missouri River Basin partners are engaged in developing the Missouri River Basin Asian Carp Control Strategy Framework, a document that briefly outlines the threat of Asian carp in the Missouri River basin

as well as actions for prevention, early detection, population control, outreach, and communication to collectively prevent further expansion, reduce populations, and better understand the impacts of Asian carp. As such, many important questions remain about bigheaded carps in the Missouri River. At this time, the Corps can contribute to this knowledge base by assessing the impacts of river regulation on spawning behavior and success as well as evaluating habitat creation projects in the Missouri River as habitat for invasive carp.

Dreissenid mussels

Zebra and quagga mussels, native to the Caspian Sea area, were introduced via ballast waters in the great Lakes in the late 1980s. They have subsequently spread across the United States. Zebra mussels were found in Lewis & Clark Lake in South Dakota in 2015. Subsequently adult mussels were found in locations throughout the reservoir and in the Missouri River downstream of Gavins Point Dam. *Dreissenid veligers* were found in two Missouri River headwater reservoirs by Montana Fish, Wildlife and Parks in 2016 samples.

Zebra and quagga mussels have extensive environmental and economic impacts. *Dreissena* species ability to rapidly colonize hard surfaces causes serious economic problems. These major biofouling organisms can clog water intake structures, such as pipes and screens, therefore reducing pumping capabilities for power and water treatment plants, costing industries, companies, and communities. Recreation-based industries and activities have also been impacted; docks, breakwalls, buoys, boats, and beaches have all been heavily colonized (Benson et al. 2016).

New Zealand mudsnail

This snail was first discovered in the middle portion of the Snake River in Idaho in 1987 and occurs in Missouri River Basin headwaters in Montana. This species is euryhaline, establishing populations in fresh and brackish water (Benson et al. 2016). It tolerates temperatures of 0–34°C (Cox and Rutherford 2000, Zaranko et al. 1997). In the United States, the mudsnail populations consist of asexually reproducing females that are born with developing embryos in their reproductive systems. The mudsnail is hardy and able to withstand a trip through a fish's gut.

Curly-leaf pondweed

This plant native to Eurasia was first found in the United States in the mid-1800s. The plant forms dense mats which inhibit growth of native species. Late summer die-off may lead to algal blooms and oxygen depletion, impacting fish. The plant may be spread by segments attached to boats and other equipment. The plant occurs in the Missouri River Basin headwaters in Montana, in Lake Sakakawea in North Dakota and in Burbank Lake (a Missouri River oxbow) in South Dakota (Thayer et al. 2016).

Eurasian Watermilfoil

This plant species is native to Eurasia, Asia and North Africa. Means of introduction to the United States is unknown but may have been introduced near Maryland in 1940 as part of the aquarium trade. Typical dense beds restrict swimming, fishing and boating, clog water intakes and result in decaying mats that foul lakeside beaches. Transport on boating equipment plays the largest role in introducing fragments to new waterbodies. (Pfingsten et al. 2016).

Most states in the Missouri River basin have developed plans or guidance to help reduce the spread of injurious and invasive species and we encourage the Corps to consult those plans and

undertake appropriate actions relevant to Corps operations. It is important to train staff to help identify invasive species they may encounter and the mechanisms they can undertake to avoid spreading invasive species in the course of their work. Many of the aquatic invasive species require extra diligence in cleaning boats, trailers and equipment to avoid transfer of aquatic invasive species when working on multiple water bodies.

BSNP Mitigation

While we recognize the purpose of the MRRMP focuses on ESA listed species, the Service is committed to an ecosystem approach for the benefit of fish, wildlife and people. We believe the MRRMP-DEIS does this in Section 3.5 Fish and Wildlife; Section 3.6 Other Special Status Species; and Section 3.23 Ecosystem Services. Lands acquired through the BSNP Mitigation Program have made important contributions to the ecological health of the Missouri River benefitting a variety of species which "include birds, fishes, mammals and all other classes of wild animals and all types of aquatic and land vegetation upon which wildlife is dependent" (FWCA, 16 U.S.C. 666(b)).

The BSNP Mitigation Project was authorized by WRDA of 1986 for a total of 48,100 acres to be mitigated. Section 334 of WRDA 1999 increased the acreage of habitat to be mitigated for the BSNP Mitigation Project by 118,650 acres, bringing the total acres to be mitigated to 166,750 acres. This authorized acreage is roughly 32 percent of the 522,000 acres of fish and wildlife habitat lost between 1912 and 1980 due to construction of the BSNP (USACE 2003). The BSNP Mitigation Project authority was further amended in Section 3176(a) of WRDA 2007 allowing funds made available for recovery or mitigation activities in the lower basin of the Missouri River to be used for recovery or mitigation activities in the upper basin of the Missouri River, including the states of Montana, Nebraska, North Dakota, and South Dakota. Under the selected alternative in the 2003 Record of Decision (ROD) of the Supplemental EIS for the BSNP Mitigation Project, restored habitat types would include wetlands, bottomland forest, native prairie, chutes and side channels, shallow water habitat (SWH), backwater areas, and slack water habitats and USACE (2003) states that the mitigation project implementation period is at least 30 years. To date, the important obligations of the BSNP Mitigation Project are still being undertaken and remain relevant and unchanged.

Subsequently, the preferred alternative results in limited habitat restoration activities that restore the overall natural ecology of the river separately and distinctly from activities specifically to avoid jeopardy. Habitat restoration on mitigation lands can benefit multiple non-listed species, including species at risk, such as the American eel (*Anguilla rostrata*), black buffalo (*Ictiobus niger*), burbot (*Lota lota*), flathead chub (*Platygobio gracilis*), sicklefin chub, sturgeon chub, paddlefish (*Polyodon spathula*), plains minnow (*Hybognathus placitus*), and western silvery minnow (*Hybognathus argyritis*), not just the pallid sturgeon, interior least tern and the piping plover. Over time, by focusing on the listed species only, the overlap of the value of mitigation lands for other non-listed species may be diminished. While the BSNP Mitigation Project can be complementary and beneficial to ESA compliance, it was developed for the Corps to be in compliance with the FWCA. Habitat and its associated ecological functions are the keys to a healthy ecosystem that will provide the needs of all fish and wildlife on the Missouri River.

As noted previously, the Service was recently petitioned to consider listing sturgeon chub and sicklefin chub under the Endangered Species Act and we believe the MRRMP provides an opportunity to engage in actions that can be beneficial to an array of native fish and wildlife

species and also informative when the Service makes a decision on these two petitioned chub species. In particular, we believe that further monitoring and understanding of the life histories of sicklefin and sturgeon chubs will be beneficial to the these species' status assessments which are likely to begin in 2021. Further, if the Corps is able to implement parts of the MRRMP that provides benefits for these chubs species, there should be an opportunity to consider those actions when the 12-month findings are completed in fiscal year 2023. The Corps is an important partner in the conservation of sicklefin and sturgeon chubs on the Missouri River and we believe the MRRMP can help conserve these species.

Additionally, numerous studies have documented the effects of operations on the biological and physical characteristics of the river in the upper Missouri River (Owen and Hahn 2014). Spring freshets have been eliminated resulting in severely reduced inundation of highly productive lateral floodplain habitats, hypolimnetic withdrawals have significantly decreased late spring and summer water temperatures, and suspended sediments and nutrients have been greatly reduced. The result is that the carrying capacity for pallid sturgeon and other native species has probably been reduced. Several studies have indicated that Ft. Peck Dam operations have negatively affected the abundance of several Montana species of concern including; sicklefin chub, sturgeon chub, paddlefish, shovelnose sturgeon, channel catfish (*Ictalurus punctatus*), blue sucker (*Cycleptus elongatus*) and smallmouth (*Ictiobus bubalus*) and bigmouth buffalo (*Ictiobus cyprinellus*).² Channel simplification has been occurring since impoundment with documented reductions in side channel, backwater and secondary channel habitats, which has a direct impact on habitat availability for native fishes, including forage fish for pallid sturgeon (Owen and Hahn 2014). Since Section 3176 of WRDA 2007 expanded authority to the Corps to conduct mitigation activities in upper basin states, we suggest that the Corps provide clarification in the Management Plan if mitigation activates will be conducted in the upper basin.

Again the Service recognizes the purpose of the MRRMP is focused on developing management actions to meet the needs of the federally listed species and we commend the Corps for including the BSNP Mitigation Program in the conservation strategy in the Section 7(a)(1) Conservation Plan (USACE 2017, Appendix D). We recommend the Corps further clarify and describe the role and intent of the MRRMP in meeting the needs of the BSNP Mitigation Program; and to expeditiously develop implementation guidance that describes how the expanded BSNP mitigation authority will be applied in the upper non-channelized portion of the Missouri River basin to mitigate for impacts to the non-listed native fish and wildlife species.

Fish and Wildlife Recreation

The Missouri River is a significant resource for recreation on the Missouri River that enriches the lives of the people who live and depend on it. Approximately 100,000 acres of BSNP habitat mitigation is authorized and if implemented represents an opportunity for enhanced public recreation, restoration of lost habitat for fish and wildlife, and ecological sustainability that is necessary to also maintain a wide variety of uses along the river, including agricultural, water

² (Braaten and Fuller 2007, Braaten et al. 2008, Braaten et al. 2009, Braaten et al. 2012a, Braaten et al. 2012b, Bramblett and White 2001, Clancey 1989, DeLonay et al. 2010, DeLonay et al. 2014, DeLonay et al. 2016, Dieterman et al. 1996, Fuller and Haddix 2012, Fuller and Braaten 2013, Fuller et al. 2008, Galat and Lipkin 1999, Gardner and Stewart 1987, Eichelberger et al. 2014, Liebelt 1996, Liebelt 1999, Liebelt 2000, USACE 2004, USFWS 2000, White and Bramblett 1993, Young et al. 1997)

supply, and other uses. Science-based planning can promote agriculture, ensure sustainable economic development, and enhance fish and wildlife benefits.

The states along the Missouri River have an interest in maintaining all forms of recreational use of the natural resources on the River. Missourians, for example, support fish, forest, and wildlife conservation with over 95 percent indicating their interest. Over two million residents and visitors participate in fishing, hunting, or wildlife-associated recreation in Missouri. There is over \$12 billion economic impact in Missouri from wildlife-related recreation and the forest products industry across the state; fish and wildlife recreation and the forest products industry support over 99,000 jobs. Most Missourians agree (76 percent) that the Missouri Department of Conservation should make an effort to restore animals that once lived or are currently very rare in the state. Together, these figures illustrate that Missourians place value on sport species as well as native, non-game species. Recreation impacts on the Missouri River in Missouri and along shared borders are upwards of \$38 million, which enriches the Missouri economy and quality of life. Acquisition of land for habitat mitigation within the BSNP Mitigation Project is an important tool available to restore the loss of these recreational uses in the BSNP area.

Riverine Form and Function

The Service believes the most successful strategy to provide for the long term sustainability of fish and wildlife resources of the river is to ultimately work towards a flow corridor that includes the desired physical features and biological functions while also providing for other project purposes to the maximum extent practicable. A functional flow corridor would reduce flood risks to infrastructure and other human considerations through increased conveyance and provide sustainable conditions for fish and wildlife populations. Some native fish populations in certain reaches are in very low condition and ultimately may depend on a more holistic approach to improve their habitat and the ecological processes to support their needs. In an effort to prevent further declines of other native species and avert future listings of additional species, the Service recommends that the Corps incorporate practices and principles into the future design and construction of habitat projects, to achieve benefits for all fish and wildlife resources. We believe a functional flow corridor that provides the physical features and biological functions that will sustain ESA listed species will also provide benefits to a wide array of native fish and wildlife species.

Habitat Creation

Habitat creation/restoration is a fundamental need along the river. With the loss of over 522,000 acres of meander habitats with only about 40 percent currently in public conservation, land, fish and wildlife simply need a larger habitat base if they are to maintain sustainable populations into the future. Much of the aquatic habitat restoration in the lower river may require some form of mechanical creation (i.e., structure modification, dredging of chutes/backwaters/access channels). At the same time, it is important to use our ever expanding knowledge base to find the "sweet spot" of mechanical habitat creation and habitat formation via processes naturally occurring in the river. We anticipate that aquatic habitat creation will be the most resource intensive and should use a combination of techniques depending on the opportunities at any one location.

One of the most important considerations in plan formulation should be to not preclude future opportunities to modify, improve, or redesign project features as conditions on the river continue to change. Sustainability will be critical and should be thought of in terms of sustainable

processes and a range of functions rather than a single project design (i.e., 95 percent plans and specs). This should be viewed at a reach level to incorporate synergy among multiple projects and their effects on the hydraulics of the river and other project purposes. Use of expensive and intensive project features (i.e., pumping) should be considered only in especially rare circumstances, since they will likely be unaffordable over the long term. The need to maintain a viable connection between groundwater and surface water floodplain habitats will make it all the more important to address continued bed degradation along the river.

Emergent Sandbar Habitat (ESH)

Fortunately, over 14,000 acres of ESH were created by the 2011 flood event, which exceeds even the amount of habitat recommended in the 2003 Amended Biological Opinion of 11,886 acres. Due to this increase in nesting habitat, tern and plover numbers have also greatly increased. However, the 2015 Annual Report states these acres have been reduced in 2015 to approximately 7,280 acres in the system via wind and water flow erosion and vegetation encroachment. We appreciate that the focus of the ESH program has been to maintain as much of this habitat for as long as possible through vegetation removal. Considering the high rate of ESH erosion and the multi-year budget process, construction of these habitats within the SAMP framework should be initiated now to start building new tern and plover habitat within the next couple of years. For reaches where ESH has not been constructed in the past, it is especially important to begin the learning process in these areas to inform future construction efforts.

Interception and Rearing Complexes

We recommend that we continue to learn from our existing within-channel and shallow water habitat projects which appear to have varying site-specific results, providing a range of values to the Missouri River aquatic ecosystem. Based on much of the recent science in the Missouri River on small/young fish, it appears those fish need slower water areas which are rare in most of the current channel. Enlarging the river through channel widening will allow more within bank, but off-main channel habitats to form. Ideally, these areas should be accessible by fish and other aquatic organisms over a wide range (but not necessarily all) of river stages over the course of most years. The Service recommends widening the river as wide as is needed to provide the necessary functional habitats in reaches where it has been narrowed the most. The project at Deer Island widened the river more than double the 250 feet width listed for this reach and we are not aware of any problems with other purposes.

Our understanding regarding using structural modifications to create functional habitats continues to evolve. Structural modifications have been used to modify the river and create habitat for the piping plover, least tern, and pallid sturgeon, but additional work is needed to understand and quantify what kinds and quality of habitat have been created. We support evaluating these structural modifications and the associated biological responses through the SAMP.

Sediment management

Sediment is important to river channel morphology and to maintaining complex ecological habitat (Funk and Robinson 1974; Hesse and Mestl 1993). It engenders particular morphologic channel characteristics such as sinuosity, and generates habitat types such as sandbars (NRC 2002). Sediment moves as suspended matter and as bed load, successively picked up, moved, and redeposited by the varying channel and overbank flows (Junk et al. 1989; Hesse and Mestl 1993; Poff et al. 1997; Galat et al. 2005). The size of the suspended sediment particles

transported by the river and the substrate sediment particles moved along the bed affect the quality and types of habitat conditions in the river and across its backwaters and side channels (NRC 2002; Galat et al. 2005). For example, the size and quantity of suspended sediment particles largely determine the turbidity of the water, which is a substantive factor affecting the types and densities of aquatic organisms that can live in the river (Bonner and Wilde 2002; Blevins 2006). This also affects the transport of some nutrients adhering to mineral particles (Sprague et al. 2006). Sediment is the most important building material contributing to river and floodplain macrohabitat complexity (NRC 2002; Sluis and Tandarich 2004), and helps determine the flora and fauna of the river and floodplain (Johnson 1992; Rood et al. 2003; Sluis and Tandarich 2004).

To preserve the functionality and sustainability of river habitat improvement projects and to maintain the viability of water resource and infrastructure investments, it is imperative that the Corps develop and implement a strategy to restore the dynamic equilibrium of sediment transport and associated turbidity within the SAMP. River reach specific issues associated with channel incision and sediment aggradation are already compromising opportunities to provide these important river benefits.

Levee setbacks and Floodplain connectivity

While we recognize that levee setbacks and floodplain connectivity are currently not identified as habitat improvement projects, or even identified through the Effects Analyses (Jacobson 2016) as potential management actions, we recommend that they be considered for future project development in the SAMP. Tools are rapidly developing to carefully analyze the potential benefits (i.e., habitat, flood risk reduction, economic, infrastructure) of strategic levee setbacks that may not only meet the species objectives, but also provide reach-wide benefits for flood damage reduction, and reduce Federal flood repair expenditures. Such features would allow terrestrial and aquatic habitat creation and increase floodplain connectivity with the river. That would increase seasonally available slow water habitats for fish spawning and nursery areas, and also meet the needs of a myriad of fish and wildlife species consistent with the Corps' mitigation responsibilities.

Connectivity between instream habitat types and the floodplain is an important component for a healthy functioning riparian ecosystem. The Service remains concerned about the lack of incorporation of floodplain connectivity within IRC habitat actions for the Lower River Pallid Sturgeon in Alternatives 3-6. The Effects Analysis (Jacobson 2016) describes how IRC habitats benefit from increased floodplain connectivity. Incorporating floodplain connectivity actions, while providing benefits to pallid sturgeon, would benefit a large number of other native species. Enhanced floodplain connectivity starting just below Gavins Point could provide the nutrients and processes needed to support the aquatic ecosystem and may be critically important to pallid sturgeon given the condition issues within this reach.

Flow modifications

We recommend continued progress on the previous items to provide a better foundation on which to strategically improve river flows to benefit native fish and wildlife species. The development of a flow corridor could allow for flows that do not impact infrastructure while providing for ecological needs. At the same time, a flow corridor would enhance flood risk reduction during natural high flow events. Floodplain connectivity with associated flow events

can provide for critical lower flows and warmer water to enhance productivity of the Missouri River system.

In contrast, lower flow experiments may not depend on additional land acquisition. Given the increasingly compelling need for slow water for successful native fish recruitment (based on our 10+ years of monitoring and research), and the recommendations of the Missouri River Recovery Implementation Committee (MRRIC) and the Independent Scientific Advisory Panel, we believe carefully designed, implemented and monitored flow experiments with specific decision triggers could help us answer several critical questions regarding pallid sturgeon age 0-1 life stage, as well as other native fishes. In addition, such experiments would also allow us to understand effects to other project purposes or adjacent lands and develop measures to address them as appropriate. As the MRRMP is implemented, we recommend that the Corps continue to consider the full range of flows from magnitude, seasonal, and duration perspectives along with the impacts and benefits of associated flow corridor and habitat modifications.

Flows are a critical part of aquatic habitat creation, maintenance, and function. A much larger range of habitats (macro, meso, and micro) and functions is available in the lowest reaches of the river. While some of this is simply due to the size of the river, much of it is a result of the variability of river flows over the course of the year. In monitoring aquatic habitat development, it is clear that areas with more flow diversity develop faster and provide more diverse habitats and functions than areas with consistent flow farther up the river. In a future of likely declining budgets, it is imperative to formulate project features that work with the river to the maximum extent practicable. It is also critical to carefully characterize the economic implications of all the options so decision makers and the public understand why various alternatives were chosen.

Land Acquisition and Flowage Easements

A land base is critical to implement projects necessary to meet both the species and mitigation goals. Many of the critical river processes needed to support these species can only occur with a larger land base connected to the river (i.e., much like the Mississippi and Atchafalaya River systems). Such lands should allow for both terrestrial and aquatic habitat creation/restoration and processes while providing a secure flood conveyance corridor that would minimize flood damages on adjacent lands, infrastructure, and public safety, much like the original Pick-Sloan plan. The details of this could be based on site-specific engineering, land opportunities and hydrologic modeling. Flowage easements could be considered if they facilitate modest levee relocations to a hydraulically improved (from a flood damage reduction perspective) alignment. Such a corridor would provide added operational flexibility for flood damage reduction and potentially reduce Federal investments long-term by avoiding costly and repeated levee repairs and disaster payments due to poor alignment (and which costs should be included in the cost benefit analyses).

Real estate is the foundation for conservation of fish and wildlife on the Missouri River by providing opportunities to restore and manage habitats. We recommend the Corps give equal consideration for native wildlife in addition to threatened and endangered species by continuing to acquire floodplain lands from willing sellers, of privately owned lands by fee title or conservation easement at a rate necessary to conserve and restore all habitats, such as shallow water, riparian forests, and wetlands. Land acquisition priority should include lands with river channel frontage, low-lying, poorly drained lands, lands at major tributary confluences, and lands with restorable side channels, chutes, and backwaters.

Project Plan Alternatives

The following are the descriptions of the proposed alternatives contained in the MRRMP:

Alternative 1 – No Action (Current System Operation and Current MRRP

Implementation): The MRRP would continue to be implemented as it is currently. The current program does not implement all RPAs included in the 2003 Amended Biological Opinion (USFWS 2003). The Corps would mechanically construct ESH annually at a rate of up 46 to 107 acres per year across the entire system. The Corps support of pallid sturgeon propagation and augmentation efforts would continue at current levels. Construction of habitat to support early life history requirements of pallid sturgeon would occur as part of the shallow water habitat (SWH) program. The Corps would achieve the low end of the 2003 Amended Biological Opinion (USFWS 2003) SWH target of an average of 20 acres of SWH per river mile between Ponca, Nebraska, and the mouth of the river. The Corps would also continue to implement the plenary spring pulse as described in the Master Manual and Corps monitoring and research program for pallid sturgeon. An adaptive management (AM) approach would also continue to be implemented for the ESH (USACE 2011) and the SWH creation (USACE 2012c) programs.

Alternative 2 – U.S. Fish and Wildlife Service 2003 Biological Opinion Projected Actions:

This alternative represents the Service's interpretation of the management actions that would be implemented as part of the 2003 Amended Biological Opinion RPA (USFWS 2003). This alternative includes Alternative 1 and additional iterative actions and expected actions that the Service anticipates would ultimately be implemented through AM and as impediments to implementation were removed. Actions would include:

- Mechanical Emergent Sandbar Habitat Construction
- Spring Habitat-Forming Flow Release
- Lowered Nesting Season Flows
- Pallid Sturgeon Propagation and Stocking
- Pallid Sturgeon Early Life History Habitat Construction
- Spring Pallid Sturgeon Flow Releases
- Summer Low Flow
- Floodplain Connectivity
- Monitoring, Research and Adaptive Management
- Additional land purchases

Actions Common to Alternatives 3–6

Under Alternatives 3–6, the USACE would implement an AM program. Specific AM actions would be implemented focused on understanding limiting factors associated with least terns and piping plovers, as well as pallid sturgeon.

- **Level 1 and 2 Studies:** The Corps would implement level 1 and 2 studies under Alternatives 3-6 for better understanding limiting factors associated with pallid sturgeon. Level 1 studies are research focused that do not change the system (Laboratory studies or field studies under ambient conditions). Level 2 studies would focus on in-river testing of actions at a level sufficient to expect a measurable biological, behavioral, or physiological response in pallid sturgeon, surrogate species, or related habitat response. Some level 2 studies would be outside the scope of the MRRMP/EIS and require additional compliance with NEPA.
- **Spawning Habitat:** Under Alternatives 3–6, the Corps would create three high-quality spawning habitat sites, and monitor the effectiveness of this action in terms of the relative

use of these sites compared to other control areas, and the relative spawning success, as determined by hatch rate, catch per unit effort of free embryos and other indicators. These sites would be constructed following initial studies to further clarify habitat specifications. An early emphasis would use information from the Yellowstone River as the best natural reference condition to inform the design of these pilot projects on the Lower Missouri River, while also continuing to examine the habitat characteristics of spawning sites on the Lower Missouri.

- **Channel Reconfiguration for Interception and Rearing Complexes:** Under Alternatives 3–6, construction of habitat to support early life history requirements of pallid sturgeon would occur following the IRC (interception and rearing complexes) concept. Best available science indicates that future acreage required to construct IRCs would most likely be achieved through channel widening. For the purposes of evaluating potential impacts to the human environment, modeling assumed that about 3,380 acres of channel widening would be implemented to create IRCs under Alternatives 3–6.

Alternative 3 – Mechanical Construction Only:

The Corps would only create ESH habitat through mechanical means at an average rate of 391 acres per year across the entire system. This amount represents the acreage necessary to meet the bird habitat targets after accounting for available ESH resulting from System operations. The average annual construction amount includes replacing ESH lost to erosion and vegetative growth, as well as constructing new ESH. The results of ESH availability modeling indicate that under Alternative 3, ESH construction would occur in 75 percent of the 50 years modeled. In the remaining years, the model indicates there would be sufficient ESH on the system that construction would not be necessary.

Alternative 4 – Spring Emergent Sandbar Habitat (ESH) Creating Release:

Alternative 4 would include the three specific AM actions focused on understanding limiting factors associated with the listed species. The Corps also would mechanically construct ESH annually at an average rate of 240 acres per year across the entire system. This amount represents the acreage necessary to meet the bird habitat targets after accounting for available ESH resulting from implementation of a Spring ESH-creating reservoir release. The average annual construction amount includes replacing ESH lost to erosion and vegetative growth, as well as constructing new ESH.

Alternative 4 reservoir operations would be similar to Alternative 1 (current operations), with the addition of a high spring release designed to create ESH for the least tern and piping plover. In any year, the implementation of this habitat-forming flow release would occur if System storage is at 42 MAF or greater on April 1, natural flows creating 250 acres of ESH have not occurred in the previous four years, and downstream flow is below identified flood control constraints specific to this alternative. If those conditions are met, the habitat-forming flow release would be implemented on April 1 with a release of up to 60 kcfs out of Gavins Point Dam, and as often as every four years. To achieve the Gavins Point Dam release, Fort Randall Dam releases would be increased a similar amount as Gavins Point and releases from Garrison Dam would be approximately 17.5 kcfs less than the Gavins Point release.

Alternative 5 – Fall ESH Creating Release:

Alternative 5 would include the three specific AM actions focused on understanding limiting factors associated with the listed species. The Corps also would mechanically construct ESH

annually at an average rate of 309 acres per year across the entire system. This amount represents the acreage necessary to meet the bird habitat targets after accounting for available ESH resulting from implementation of a Fall ESH-creating reservoir release. The average annual construction amount includes replacing ESH lost to erosion and vegetative growth, as well as constructing new ESH.

Alternative 5 reservoir operations would be similar to Alternative 1 (current operations), with the addition of a high fall release designed to create ESH for the least tern and piping plover. In any year, the implementation of this habitat-forming flow release would occur if the service level is at 35 kcfs or greater (54.5 MAF System storage) on October 17, natural flows creating 250 acres of ESH have not occurred in the previous four years, and downstream flow is below identified flood control constraints. Downstream flood control constraints for Alternative 5 would be the same as that for Alternative 4. If those conditions are met, the habitat-forming flow release would be implemented on October 17 with a release of up to 60 kcfs out of Gavins Point Dam, and as often as every four years. To achieve the Gavins Point Dam release, Fort Randall Dam releases would be increased a similar amount as Gavins Point and releases from Garrison Dam would be approximately 17.5 kcfs less than the Gavins Point release. As with Alternative 4, the duration of the release would increase as release magnitude is decreased. If flood targets are exceeded, the Gavins Point release would be reduced by 5 kcfs until flood targets are no longer exceeded. In instances where the Gavins Point release falls below 45 kcfs, the release would be terminated.

Alternative 6 – Pallid Sturgeon Spawning Cue:

Alternative 4 would include the three specific AM actions focused on understanding limiting factors associated with the listed species. Under Alternative 6, the Corps would also mechanically construct ESH annually at an average rate of 303 acres per year across the entire system. This amount represents the acreage necessary to meet the bird habitat targets after accounting for available ESH resulting from System operations, which includes a spring pallid sturgeon flow release. The average annual construction amount includes replacing ESH lost to erosion and vegetative growth, as well as constructing new ESH.

The Corps would attempt a spring pallid sturgeon flow release every 3 years consisting of a bimodal pulse in March and May. These flow releases would not be started or would be terminated whenever flood targets are exceeded.

Analysis of the Evaluation Methods

Estimation of project-related habitat changes is a fundamental technique used to assess project impacts to fish and wildlife resources. Those estimates also form the basis of other Corps evaluations such as alternatives analyses and benefits/costs. For this effort, the Corps used a number of models to describe potential impacts to fish and wildlife habitats. While helpful, there are important aspects of the biological response of many native fish and wildlife species that cannot be told by only evaluating modeled habitats. We recommend that current fish and wildlife monitoring data be used to complement the models results to verify fish and wildlife responses to the specific management actions in the alternatives analyses. We recommend that the AM program include monitoring for guilds of fish communities, which would be a good indicator of the health of listed species populations and functionality of their habitat.

Another important aspect of alternatives analyses is consistency and crosswalks among evaluation tools. During model development, the Service noted metrics from other HC groups could have direct applicability to fish and wildlife resources. For example, modeling of river inundation for flood risk and damages may have direct relevance to the timing, distribution, and duration of habitats important to fish and wildlife. Although the technical appendices indicate different models may have been used in estimating aquatic floodplain fish and wildlife habitats, it is not clear how or whether these analyses have been cross-walked with other evaluation tools. This is important to understand the accuracy, precision, and logic of model outputs and effects on fish and wildlife.

Connectivity between habitats via water is necessary for many species to access habitats at the right time to meet their life history needs. Future analyses should address connectivity of habitats, either through models, or the discussion of model results to put them in proper context. This is an example where habitat for one suite of species is not accessible habitat for other groups. This level of analyses is currently not found in the model results or discussion of fish and wildlife effects.

Evaluation of the Alternatives

The Service recognizes the difficulty in developing and analyzing alternatives that rely on adaptive management to define the alternatives themselves. We understand the current range of alternatives and applaud the Corps on their efforts to disclose their impacts on fish and wildlife resources of the Missouri River Basin. The Service acknowledges that each of the described action alternatives, bounded within the adaptive management framework, achieves the Management Plan's fundamental objectives; with this it is difficult to ascertain how much they advance other native fish and wildlife conservation in general. Specifically, it should also be recognized that success may ultimately only be achieved through the implementation of an array of actions currently not contained in any one specific alternative or even fully realized to date.

The draft MRRMP indicates that the BSNP Mitigation Project is intended to help reestablish a part of the natural ecology of the river and that the need to meet the objectives of the BSNP Mitigation Project are still relevant and remain unchanged. The Service encourages the Corps to describe in the MRRMP how the plan fulfills the scope and intent of the BSNP Mitigation Project for fish and wildlife resources. Doing so could help dispel concerns that the BSNP mitigation program is being deemphasized. Again, as noted in the planning aid letters dated June 18, 2014, April 28, 2016, and October 7, 2016, the Corps should describe plans to meet their mitigation responsibilities to all native fish and wildlife species on the river throughout the basin.

Monitoring

We recommend that changes to the monitoring program for implementation of the MRRMP also be in cooperation with technical experts in the Service and the state fish and game agencies. Further, we believe there are benefits to a more holistic approach that includes not only threatened and endangered species monitoring, but monitoring other species of concern, native species, and aquatic invasive species which will help our agencies understand the effects of implemented management actions.

A holistic monitoring approach should assess the status of physical drivers, physical conditions and ultimately ecosystem biotic conditions as outlined in Table 2. A monitoring program that incorporates such an approach will be important to understanding how alterations to the Missouri River system to facilitate recovery efforts for the listed species may provide information to inform other fish and wildlife species and provide conservation benefits to other fish and wildlife species and their needs. The opportunities to monitor other native fish and wildlife species while conducting monitoring for the three listed species can provide important data to inform management for multiple species. For example, while doing pallid sturgeon monitoring, it may be possible to also evaluate the forage fish community which can help inform pallid sturgeon recovery but also help address specific Endangered Species Act Petitions for fish like sicklefin and sturgeon chubs.

Recommended Fish and Wildlife Conservation Measures

We recognize the MRRMP-EIS is an effort to incorporate new scientific information into management actions for pallid sturgeon, least terns, and piping plovers and to develop an Adaptive Management Plan. While we believe the MRRMP will also have benefits to other fish and wildlife resources even though its focus is for listed species, a FWCA report provides an opportunity to discuss conservation actions that are broader than listed species. The Service provided preliminary recommendations on several specific measures we believe are valuable to realize our conservation objectives along the river, consistent with other project purposes and meeting the Corps BSNP Mitigation Project obligations. We encourage these measures be incorporated wherever possible as implementation, assessment and adaptation of the MRRMP and SAMP move forward. We reiterate them here:

BSNP Mitigation - We continue to believe this is an important component of Missouri River recovery and encourage the Corps to seek funding through various mechanisms available to your agency. We recommend the Corps continue to seek ways to maintain flexibility to meet the needs of all fish and wildlife species and seek opportunities to continue to implement the BSNP Mitigation Project within the MRRP. In concert with state partners, develop guidance on how mitigation will be applied in the upper non-channelized portion of the river to mitigate for impacts to the non-listed native fish and wildlife species.

Ecosystem Management - We recommend that as the MRRMP and SAMP commences, they progress towards a comprehensive approach to river management and that we analyze the impacts of the current and future Corps actions in the context of a functioning and resilient river ecosystem, in addition to the three listed species.

Floodplain Connectivity - We recommend that the Corps continue to acquire floodplain lands from willing sellers, by fee title or conservation easement at a rate necessary to conserve and develop habitat to sustain all endemic fish and wildlife, such as cottonwood forests, and wetlands; and restore lost recreational opportunities. Develop floodplain connectivity starting just below Gavins Point to the confluence to provide the nutrients needed to drive the aquatic ecosystem and restore habitat connectivity.

Flows - We recommend that the Corps continue to consider the full range of flows from magnitude, seasonal, and duration perspectives along with the impacts and benefits of associated land purchases and habitat modifications. We support developing experiments for flows to

assess the ability to attract spawning adult pallid sturgeon during May-July to help us answer several critical questions regarding pallid sturgeon early life history during July-September, and to understand the resiliency of other native fishes and their roles as pallid sturgeon forage. In particular, for the Missouri River between Fort Peck Dam and Lake Sakakawea, understanding the relationship between flows, temperature, drift distance, and the survival of larval pallid sturgeon could be key in the recovery of the species. Additionally, any scenario that evaluates the modification of Fort Peck Dam operations to enhance pallid sturgeon reproductive opportunity and larval survival in this stretch of river must also concern itself with the potential impact of those operational changes on river-reservoir dynamics in the Missouri River above Fort Peck Dam and how pallid sturgeon and other fisheries might be affected.

We also recommend that the analysis of this alternative include the additional life history benefits to the sturgeon and other fisheries that a spring flow would provide; and that the description of this alternative reflect the larger role that flow plays in the life history of the pallid sturgeon and other aquatic organisms.

Invasive and Injurious Species - We recommend that the Corps coordinate with the states on best management practices for dealing with specific invasive species. Field crews that work within the range of these species should be trained to identify invasive species and be familiar with the best management practices to prevent the spread of these species. We recommend that the Corps contribute to the knowledge base of Missouri River bigheaded carps by assessing the impacts of river regulation on spawning behavior and success, evaluating habitat creation projects in the Missouri River as habitat for invasive carp and what can be done to avoid increasing carp populations. Consider the cumulative impacts of other invasive and injurious species in the MRRMP.

Sediment management and bed degradation - We recommend the Corps continue their efforts to address bed degradation along the river, or any habitats we try to restore will likely be ineffective and/or short-lived. As the river bed degrades, water becomes less available to flow into constructed habitats, provide floodplain connectivity, or human uses. River bed degradation underpins all other issues and it is one of great interest to the basin stakeholders.

Monitoring - We recommend that changes to the monitoring program also be in cooperation with the Service and State Fish and Game Agencies and include a holistic approach that includes not only threatened and endangered species, but other species of concern, native species, and aquatic invasive species to help understand the benefits or detriments of implemented management actions. The holistic monitoring approach should assess the status of physical drivers, physical conditions and ultimately ecosystem biotic conditions as outlined in Table 2.

Coordination with Partners - We recommend the Corps continue to coordinate with the Service and State Fish and Game Agencies as individual projects are developed. In particular, when habitat improvement projects are being planned by the Corps, if those site specific projects are coordinated with the relevant State Game and Fish Agency, it would give an opportunity to cooperate on actions that might provide additional conservation benefits to fish and wildlife resources. For instance, when a project has mobilized the necessary equipment to undertake a project, if there are adjacent or nearby projects that could benefit from those resources being in the area, coordination could magnify the conservation benefits accrued if additional projects could be addressed at the same time.

Summary of Findings and FWS Position

The Service commends the Corps for committing to an adaptive management process, commencing with the science based effects analysis, and engaging with the Missouri River Recovery Implementation Committee in developing this management plan for the three listed species. These are critical components in successfully sorting through the highly complex issues and great uncertainty that has confounded previous attempts to establish management paradigms. As the MRRMP and SAMP commence implementation, it will be imperative to maintain a similar level of focus on the science, transparent communication with stakeholders, and deliberative analysis of emerging information to ultimately address the species ecological needs, and determine the best tools and actions with which to meet those needs.

As noted in our February 5, 2014 letter, as part of the MRRP, the Service encourages, the Corps to continue to seek opportunities to accelerate the effort to fulfill their BSNP mitigation responsibilities and advance opportunities to maintain flexibility to meet the needs of all fish and wildlife species while simultaneously implementing the MRRMP.

Planning and Policy Division

AUG 24 2018

Michael Thabault
Assistant Regional Director, Ecological Services
U.S. Fish and Wildlife Service
Mountain-Prairie Region
134 Union Blvd.
Lakewood, Colorado 80228

Dear Mr. Thabault:

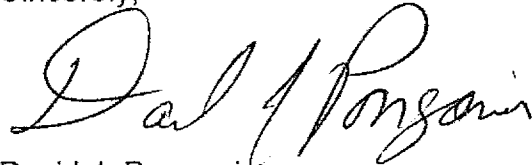

We have received your report entitled "Fish and Wildlife Coordination Act Report for the Missouri River Recovery Plan and Science and Adaptive Management Plan" (Report). Section 2(b) of the Fish and Wildlife Coordination Act (FWCA) requires reports and recommendations from the U.S. Fish and Wildlife Service (Service) and state fish and wildlife agencies on certain water resource projects to be given full consideration. The section also requires the recommendations to be included in project reports to Congress and any other relevant agency or person with approval authority over the project. The Report constitutes the Service's Section 2(b) report on the U.S. Army Corps of Engineers' (USACE) proposed Missouri River Recovery Management Plan Environmental Impact Statement (MRRMP-EIS) and Science and Adaptive Management Plan (SAMP).

As stated in the Report, the Service and state fish and wildlife agencies have worked with the USACE over the last 70 years to improve and conserve fish and wildlife resources in and along the Missouri River to benefit the public and ensure those resources receive equal consideration with the other project purposes of the Missouri River Mainstem Reservoir System (System) and the Bank Stabilization and Navigation Project (BSNP). The Service and state agencies have provided ongoing fish and wildlife recommendations throughout that time, including planning input to the BSNP Fish and Wildlife Mitigation Project and Missouri River Master Water Control Manual revisions and associated Biological Opinions under the Endangered Species Act (ESA), as well as regular coordination during project implementation. The USACE appreciates the continued participation and input from the Service and state agencies in Missouri River fish and wildlife issues, most recently, their participation in the MRRMP-EIS process. These efforts have resulted in important habitat improvements and other benefits to Missouri River fish and wildlife.

We appreciate the information and perspectives provided in the Report and look forward to continued cooperation between our agencies on Missouri River fish and wildlife issues. The Report provides information that has been shared previously through planning aid

letters and other communications through our continued coordination during the MRRMP-EIS process. The issues and information described in the Report have therefore been fully considered in the planning process. The Report, along with this response letter, will accompany the Final EIS (FEIS) that will be released to the public, and will thus be provided to the USACE Northwestern Division (NWD) Commander prior to a signing of a Record of Decision (ROD). Issues and recommendations provided in the Report and clarifications on the MRRMP-EIS and SAMP effort are included in the attachment to this letter. We look forward to continuing the long history of engagement with the Service and state fish and game agencies on Missouri River fish and wildlife management as we move forward.

Sincerely,

A handwritten signature in black ink, appearing to read "David J. Ponganis". The signature is fluid and cursive, with the first name "David" being more prominent and the last name "Ponganis" following in a similar style.

David J. Ponganis
Director of Programs Directorate
Northwestern Division
U.S. Army Corps of Engineers

USACE Responses to the final “Fish and Wildlife Coordination Act Report for the Missouri River Recovery Plan and Science and Adaptive Management Plan”- August 2018

Scope and Focus of the FWCA Report

The Report’s title and identified scope both indicate that the program being reviewed is the MRRMP-EIS and SAMP. While the Report does address the MRRMP-EIS and SAMP, the majority of the Report is focused on negative fish and wildlife impacts from construction of the System and BSNP rather than benefits to fish and wildlife from the alternatives identified in the MRRMP-EIS and SAMP. Because the scope and focus of the report is broader than the MRRMP-EIS and SAMP, we are concerned that the public, stakeholder groups, state and local governments, and Tribes may misunderstand or overlook the anticipated fish and wildlife benefits of the MRRMP-EIS alternatives and the SAMP. As a result of the Report, they may also be left with the impression that the MRRMP-EIS and SAMP falls short of its objectives and Purpose and Need. However, the MRRMP-EIS, the SAMP, the 2017 Biological Assessment (BA), and the 2018 Biological Opinion (BiOp) all conclude that the preferred alternative implemented through the SAMP will achieve the Purpose and Need and objectives. It is important to emphasize that the alternatives in the MRRMP-EIS and the SAMP are designed to benefit the least tern, piping plover, and pallid sturgeon. Furthermore, the MRRMP-EIS concludes that actions for the three listed species will not only achieve the listed species objectives, but will also have ancillary benefits to other Missouri River fish and wildlife. These benefits and impacts to fish and wildlife are presented in several sections of the MRRMP-EIS: Section 3.5 Fish and Wildlife Habitat, Section 3.6 Other Special Status Species, and Section 3.23 Ecosystem Services.

The Relationship of the BSNP Fish and Wildlife Mitigation Project and the MRRMP-EIS and SAMP

Several sections of the Report ask the USACE to further clarify and describe the role and intent of the MRRMP-EIS and SAMP in meeting the needs of the BSNP Mitigation Project. The USACE has been clear in the relationship between the BSNP Mitigation Project and the MRRMP-EIS. The focus of the MRRMP-EIS and SAMP and relationship to the BSNP Fish and Wildlife Mitigation Project are described in several sections of the FEIS and provided below:

Section 1.2 of the MRRMP-EIS presents the purpose of the MRRMP-EIS and SAMP:

“The purpose of this MRRMP-EIS is to develop a suite of actions that meets USACE ESA [Endangered Species Act] responsibilities for the pallid sturgeon, piping plover, and interior least tern. Authorities used to meet this purpose may include existing USACE authorities related to Missouri River System operations for listed species and acquisition and development of land needed for creation of habitat for listed species provided in Section 601(a) of WRDA [Water Resources Development Act] 1986, as modified by Section 334(a) of WRDA 1999, and further modified by Section 3176 of WRDA 2007 although alternatives formulation was not limited to these authorities.”

Section 1.4, presents the fundamental Objectives of the MRRMP-EIS and SAMP:

- Pallid sturgeon fundamental objective: avoid jeopardizing the continued existence of the pallid sturgeon from USACE actions on the Missouri River.
- Piping Plover fundamental objective: avoid jeopardizing the continued existence of the piping plover due to USACE actions on the Missouri River.

Section 1.5 further clarifies the scope of the MRRMP-EIS and SAMP in relation to the Mitigation Project:

"This document does not re-evaluate the entire BSNP Mitigation project but addresses the effects of land acquisition during the implementation timeframe of this EIS. The land acquisition authority and types of habitat development as described in the *Final Supplemental EIS for the Missouri River Fish and Wildlife Mitigation Project* (USACE 2003a), and the *Missouri River Bank Stabilization and Navigation Project Final Feasibility Report and Final EIS for the Fish and Wildlife Mitigation Plan* (USACE 1981) are still considered to be adequate and reasonable to mitigate the effects of the BSNP."

Section 1.8.2 of the EIS describes how the land acquisition authority from the Mitigation Project would be used to support the MRRMP-EIS and SAMP:

"The land acquisition authority used by the MRRP [Missouri River Recovery Program] for BiOp compliance is derived from Section 601 of WRDA 1986, as amended by Section 334 of WRDA 1999 and Section 3176 of WRDA 2007. This authority is limited to habitat mitigation for the effects of the BSNP and therefore cannot be separated from the requirement that lands acquired also serve to offset the impacts of the BSNP. USACE has no independent authority to acquire land for ESA compliance along the Missouri River, but USACE is able to acquire lands in areas that also constitute a necessary and proper expense under the WRDA land acquisition authority."

Section 2.5.4 describes habitat development and land management that will continue to occur on MRRP lands:

"USACE must typically purchase enough land to accommodate the habitat project and provide a buffer between the project and adjacent lands. Based on an assessment of past pallid sturgeon SWH projects implemented by USACE, it was determined that an average of 7.7 acres of land are acquired for every 1 acre of pallid sturgeon habitat needed. USACE would develop habitat on lands consistent with its authorizations under the WRDA 1986, 1999, and 2007. Habitat development has included chutes and side channels, shallow water habitat, backwater areas, slack water habitats, wetlands, bottomland forest, and native prairie. The WRDA land acquisition authority is a result of USACE mitigation recommendations under the Fish and Wildlife Coordination Act and therefore cannot be separated from the requirement that lands acquired for pallid sturgeon habitat construction also serve to mitigate for the BSNP impacts. The land acquisition authority for mitigation of the construction of the BSNP is not being reassessed through this Management Plan, and the total mitigation authority acres remain at 166,750 acres. USACE has acquired approximately 66,616 acres of the authorized 166,750 acres, nearly 40 percent. Land acquisition and habitat development under the BSNP mitigation authority is not limited to pallid sturgeon habitat and can include restoration of native vegetation, wetlands, bottomland forest, backwaters and other Missouri River habitats lost due to the BSNP. It is assumed real-estate purchases for the 15-year implementation timeframe would continue to prioritize land that contributes to jeopardy avoidance, while still constituting appropriate acquisition and development under the aforementioned WRDA authorities. Land acquisition itself does not necessarily equate to Fish and

Wildlife Coordination Act mitigation, rather, the determination of the appropriate land cover and habitat types for a parcel of land requires a site-specific analysis, which would be conducted in tandem with planning for site-specific aquatic habitat related specifically to jeopardy avoidance.

USACE has worked with USFWS and the natural resource or conservation agencies of the four lower basin states (Iowa, Kansas, Missouri, and Nebraska) to develop and implement fish and wildlife habitat restoration plans for MRRP lands acquired under WRDA authorities. Historically, USACE has established native vegetation, created wetlands, restored riparian buffers, and performed other restoration activities.

Acquired lands are managed by USACE, state fish and wildlife agencies, or USFWS."

The Section 7(a)(1) Plan (Appendix D of the Final BA) describes additional conservation strategies and measures that could be undertaken by the USACE to benefit listed species and fish and wildlife:

- Conservation Strategy 1: Identify opportunities to operate the System to benefit listed species
- Conservation Strategy 2: Support the Pallid Sturgeon Propagation and Augmentation Program
- Conservation Strategy 3: Identify opportunities to maintain the BSNP in a manner that could contribute beneficially to aquatic habitat
- Conservation Strategy 4: Prioritize land acquisition that contribute to meeting pallid sturgeon habitat requirements when consistent with BSNP Fish and Wildlife Mitigation Project authority
- Conservation Strategy 5: Consider Indiana bat and northern long-eared bat habitat needs in planning of site-specific habitat development for Mitigation Project lands
- Conservation Strategy 6: Evaluate potential for levee modifications at existing and future mitigation sites
- Conservation Strategy 7: Determine if there is potential to operate the Kansas River projects in a manner that would increase benefits to native species

Full Consideration of Fish and Wildlife Resources and Evaluation Methods

As explained in the MRRMP-EIS and SAMP, the fundamental objectives and purpose and need for the plan are focused on the three listed species. Therefore, the alternatives are focused on the three listed species. Impacts and benefits to fish and wildlife from implementation of the alternatives were given full consideration in the MRRMP-EIS effort. Three different sections describe impacts and benefits to Missouri River fish and wildlife from the MRRMP-EIS alternatives: Section 3.5 Fish and Wildlife; Section 3.6 Other Special Status Species; and Section 3.23 Ecosystem Services. The same level of effort was used to determine impacts and benefits to fish and wildlife as was used in determining impacts and benefits to the Missouri River authorized purposes and other river uses. This included using the same state-of-the-art hydrology and hydraulic modeling tools that were used to determine impacts and benefits to Flood Risk Management and other authorized purposes, in addition to other lines of evidence. The analyses in the MRRMP-EIS show that all of alternatives would have benefits to a variety of fish and wildlife species as described in those sections of the EIS.

The Report also states that the MRRMP-EIS did not analyze connectivity between habitats via water. It should be noted that habitat connectivity with river flows, and how the different alternatives might change those habitats given different flows, was the focus of our modeling efforts.

Recommended Fish and Wildlife Conservation Measures

The Report concludes by providing specific fish and wildlife conservation measures that the Service encourages to be incorporated wherever possible as implementation, assessment and adaptation of the MRRMP-EIS and SAMP move forward. We have fully considered these recommendations and provide our responses below:

BSNP Mitigation: The USACE will continue to acquire lands from willing sellers and construct habitat for listed species under the MRRMP and SAMP which will also benefit other species of fish and wildlife. The land acquisition authority and types of habitat development as described in the *Final Supplemental EIS for the Missouri River Fish and Wildlife Mitigation Project* (USACE 2003a), and the *Missouri River Bank Stabilization and Navigation Project Final Feasibility Report and Final EIS for the Fish and Wildlife Mitigation Plan* (USACE 1981) are still considered to be adequate and reasonable to mitigate the effects of the BSNP.

Ecosystem Management: While USACE understands the importance of a functional and resilient ecosystem for all species of Missouri River fish and wildlife, the USACE has been charged by Congress to meet the Missouri River authorized purposes, to meet responsibilities under the ESA, and to mitigate the effects of the BSNP through the BSNP Mitigation Project. The USACE has identified a preferred alternative that attempts to identify and correct limiting factors in the ecosystem that will allow the USACE to avoid jeopardy to the listed species and allows USACE to meet the authorized purposes.

Floodplain Connectivity: As described in the 7(a)(1) conservation plan, the USACE will evaluate potential for levee modifications at existing and future mitigation sites and continue to prioritize land acquisition that contributes to meeting pallid sturgeon habitat requirements when consistent with BSNP Fish and Wildlife Mitigation Project authority. These conservation measures will be a benefit to a variety of fish and wildlife species in addition to the pallid sturgeon.

Flows: First, The USACE has examined a full range of flows in the MRRMP-EIS process. Alternative 3 contains a one-time test of the spring pallid spawning cue pulse. Through proper implementation of Adaptive Management, if a spring pulse is found to be important to the pallid, the one-time spawning cue test will be scientifically designed to elicit meaningful results. Second, modifications at Fort Peck Dam were considered during alternatives formulation. Please see Section 2.5.21 of the Final EIS for a detailed discussion of the status of actions at Fort Peck Dam. Finally, in recognition of the scientific uncertainty surrounding Fort Peck flow adjustments, USACE agreed to formulate test flows from Fort Peck and an AM framework for their implementation during formal ESA Section 7 consultation on this plan, through an amendment to the BA. Studies under the framework may include additional drift studies, tracking of fish and documentation of spawning locations, telemetry evaluations and methodology improvements, risk analysis, and engineering studies. Implementation of an identified hydrograph to test hypotheses would be considered; however, depending on the specifics of the test hydrograph, may be outside the scope of the MRRMP-EIS.

Invasive and Injurious Species: The impacts from non-native/invasive species, including cumulative impacts, to fish and wildlife were described in Section 3.5.2.10 Invasive Species. Management actions would be performed in accordance with applicable guidance and regulation. For example, pursuant to Executive Order 13122 federal agencies may not authorize, fund, or carry out actions that are likely to cause or promote the introduction or spread of invasive species. Any management actions taken would be evaluated on a site-specific level to ensure that compliance with Executive Order 13122 is met. It is not expected that any invasive aquatic wildlife species would spread because of any of the management actions in the MRRMP-EIS.

Sediment Management and Bed Degradation: The USACE will continue to design habitat projects to function under a variety of flows in recognition of ongoing bed degradation issues. Sediment management and bed degradation and aggradation are the subject of several ongoing USACE efforts and information from these efforts will continue to be used where it overlaps with fish and wildlife issues.

Monitoring: The continued participation of the USFWS and state fish and wildlife agencies in the design and revision of monitoring programs is critical to their success. Ongoing progress on the Pallid Sturgeon Population Assessment Program (PSPAP) redesign (and opportunities for comment) can be accessed here: <https://mcolvin.github.io/PSPAP-Reboot/>. These suggestions will be considered as part of the revision of the PSPAP, as well as in development of monitoring plans to assess the effectiveness of actions.

Coordination with Partners: As stated in the MRRMP-EIS, USACE has worked with USFWS and the natural resource or conservation agencies to develop and implement fish and wildlife habitat restoration plans for MRRP lands acquired under WRDA authorities. Historically, USACE has established native vegetation, created wetlands, restored riparian buffers, and performed other restoration activities. Acquired lands are managed by USACE, state fish and wildlife agencies, or USFWS. The USACE intends to continue coordination and cooperation with partners on habitat creation efforts.

APPENDIX C: CUMULATIVE ACTIONS DESCRIPTIONS

Intentionally Left Blank

Appendix C: Cumulative Actions Descriptions

This section presents the cumulative actions that were identified and a description of each action.

Missouri River Mainstem Reservoir System Construction: The 1944 Flood Control Act (FCA) authorized the construction and operation of five large dams on the Missouri River mainstem. The projects authorized by the FCA, along with their reservoirs, are Garrison Dam (Lake Sakakawea) in North Dakota; and Oahe Dam (Lake Oahe), Big Bend Dam (Lake Sharpe), Fort Randall Dam (Lake Francis Case) and Gavins Point Dam (Lewis and Clark Lake) in South Dakota. The construction of Fort Peck Dam (Fort Peck Lake) in Montana was authorized in the Rivers and Harbors Act of 1935; however, the 1944 FCA incorporated the Fort Peck Dam along with the other five dams and reservoirs to form the System. Construction of the dams was completed in 1964.

Bank Stabilization and Navigation Project Construction: The BSNP consists mainly of rock pile structures and revetments along the outsides of bends and transverse dikes along the insides of bends to force the river into a single active channel that is self-maintaining. As authorized, the BSNP provides a 9-foot-deep channel with a minimum width of 300 feet during the navigation season from April 1 to November 30 between Sioux City, Iowa, and the mouth of the Missouri River near St. Louis, Missouri.

Missouri River Bed Degradation/Aggradation: Sediments carried by the upper Missouri River and its tributaries are deposited in the upper ends of the reservoirs. As a result, the river channel downstream of the dams deepens (degrades) as sediment that erodes from the channel floor is not replenished with sediment from upstream sources (USACE 2014d; USACE 2014e). Aside from degradation, the riverbed experiences progressive armoring. Armoring is the gradual loss of finer sediment particles and the buildup of progressively larger sediment grain sizes, such as gravel and cobbles. The channel bed at the mouths of tributaries entering a degraded reach of the mainstem Missouri River may also degrade (i.e., head cutting). In some stretches of the river, the degradation rates have decreased substantially since reservoir construction, while in other stretches degradation continues to shape the river as it seeks its dynamic equilibrium.

USACE (2017a) analyzed bed degradation in the lower Missouri River from St. Joseph to Waverly, Missouri. Within this study reach, it was concluded that commercial sand and gravel mining was the dominant cause of bed degradation observed in Kansas City since 1994 and that commercial sand and gravel mining is the dominant driver of projected bed degradation over the next 50 years.

Missouri River Depletions for Agriculture, Municipal, and Industrial Use: This action includes water withdrawals directly from the river channel and associated return flows (if any). Irrigation, agriculture, and municipal/industrial use take place on the floodplain or adjacent uplands, supplied by pumping directly from the river.

Oil and Natural Gas Production: This action includes water withdrawals for use in hydraulic fracturing technologies for oil and gas wells. Return flows of treated wastewater from these activities is possible. Hydraulic fracturing is a key element in the development of natural “shale gas” fields, of which several are under development or forecast for development in the basin. Oil

and Natural Gas Production also includes construction of infrastructure such as pipelines, roads, utilities, well pads, and staging areas.

Groundwater Withdrawal Practices: This action includes groundwater pumping for a wide range of uses, from both shallow and deep aquifers, both along the floodplain of the mainstem and tributaries and across the uplands of the basin.

Floodplain Animal Pasturing/Grazing: This action includes the use, alteration, or conversion of land in the floodplain of the mainstem Missouri River to grassland for pasturing animals.

Floodplain Development (Urban, Residential, Commercial, Industrial): This action includes a wide range of development that converts natural lands to a wide range of urban, residential, commercial, and industrial uses.

Crop Production: This action includes the conversion of land from native habitat to crop production. Extensive acreage within the floodplain of the Missouri River and its tributaries, as well as the surrounding uplands, has been converted for crop production (Bragg and Tatschl 1977; Hesse et al. 1988; National Research Council 2002).

Levee Construction (federal and private): This action includes the placement, design, and management of structures intended to prevent or control floodplain inundation.

Fishery Stocking and Management: This action includes the stocking and management of native or non-native fish that can alter the natural fish composition in an area. This includes stocking of sport-fish in reservoirs. This action also includes past, present, and reasonably foreseeable commercial fishing that has occurred on the Missouri and Mississippi Rivers.

Snag Removal: This action includes the historic removal of large woody debris from the river channel and banks. This includes removal of floating, stranded, and buried snags.

Transportation and Utility Corridor Development: This action includes the construction and maintenance of bridges, highways, local roads, railways and electrical and gas rights of way.

USACE Continuing Authority Programs (i.e., Section 514, 206, 1135): USACE has several Continuing Authority Program (CAP) ecosystem restoration authorities that have been used to restore fish and wildlife habitat in the Missouri River floodplain and could be used to fund the restoration of additional habitat in the future. These include Section 514 (Missouri and Middle Mississippi Rivers Enhancement Projects), Section 1135 (Environmental Restoration Projects), and Section 206 (Aquatic Ecosystem Restoration). The habitat created by these programs on the Missouri River has historically been minor in scope compared to the MRRP.

Management of USACE Project Properties: Missouri River project lands managed by the USACE represent a significant amount of designated fish and wildlife habitat in the study area. Project lands are divided into land classifications that govern the land uses, management activities, and level of development that are allowed. The Environmentally Sensitive, Wildlife Management, and Vegetation Management classifications are managed predominantly for fish and wildlife habitat; accordingly, the majority of restoration activities on project lands take place on these land classifications.

USACE Regulating Works Project: The USACE is responsible for providing a 9-foot-deep and not less than 300-feet-wide navigation channel on the Middle Mississippi River. This is achieved

through the Regulating Works Project. The Regulating Works Project consists of bank stabilization and sediment management to ensure adequate width and depth. Project improvements are achieved through the construction of river training structures, revetment, rock removal, and construction dredging. A record of decision was signed in August 2017 for a supplemental EIS (SEIS) prepared by the USACE to examine new circumstances and information on the potential impacts of the Regulating Works Project that were not considered in the original 1976 EIS. The Regulating Works Project is maintained through dredging and any needed maintenance to already constructed features. These present activities would continue into the future.

USFWS National Wildlife Refuge (NWR) System Lands Management: The mission of the National Wildlife Refuge System is to administer a national network of lands and waters for the conservation, management, and where appropriate, restoration of the fish, wildlife, and plant resources and their habitats. Seven national wildlife refuges are located along the mainstem Missouri River encompassing a total of 1,192,891 acres:

- Charles M. Russell NWR in north-central Montana;
- Audubon NWR in central North Dakota;
- Karl E. Mundt NWR in southeastern South Dakota;
- Desoto NWR and Boyer NWR on the Iowa/Nebraska border;
- Squaw Creek NWR in northwestern Missouri; and,
- Big Muddy NWR, which consists of several land units in the Missouri River floodplain between Kansas City and St. Louis, Missouri.

There are 40,319 acres remaining in acquisition authority for the Big Muddy NWR and 7,607 acres for Boyer Chute NWR (USACE, USFWS, 2010).

USFWS Aquatic Invasive Species Program: The USFWS Aquatic Invasive Species Program contributes to the conservation of federal trust species and their habitats by preventing the introduction and spread of aquatic invasive species, monitoring habitats to determine the distribution of invasive species, rapidly responding to new invasions, and controlling established populations. The Aquatic Invasive Species Program is made up of three elements: state plans / National Invasive Species Act of 1996 implementation, prevention, and control and management. Through the Aquatic Invasive Species Program, the USFWS provides grants for state and tribal aquatic nuisance species management plans. With approval of a state or Tribe's plan, matching funds for activities detailed in the management plan are available. Annual funding for the Aquatic Invasive Species Program nationwide is estimated at \$6.3 million.

NRCS Easement Programs (WRP and EWPP-FPE): As of 2010, a total of 67,707 acres of private lands, including Tribal lands, within the bluff-to-bluff Missouri River floodplain were enrolled in some form of NRCS easement program. These acres are primarily Wetland Reserve Program (WRP) acres (49,572 acres or 73 percent), but also include 6,527 acres enrolled in Emergency Watershed Protection Program - Floodplain Easements (EWPP-FPE), and 11,084 acres in the Emergency Wetland Reserve Program (EWRP). The EWRP was established in response to 1993 flooding in the upper Mississippi and lower Missouri River basins and is not currently active although current acreages remain in the program.

NRCS Technical and Financial Assistance Programs (e.g., CSP, EQIP, WHIP):

- **Conservation Stewardship Program (CSP):** The CSP is a conservation assistance program that supports stewardship of private agricultural lands by providing payments for maintaining and enhancing natural resources. The annual payment is based on the level of conservation stewardship achieved. The seven Missouri River basin states averaged a total of \$1 million in CSP funding annually from 2005 to 2010.
- **Environmental Quality Incentives Program (EQIP):** The EQIP program provides technical, financial, and educational assistance to farmers and other private landowners to help plan and implement conservation practices that address natural resources concerns and for opportunities to improve soil, water, plant, animal, air, and related resources on agricultural land and non-industrial private land. The seven Missouri River basin states averaged a total of \$199.7 million annually in EQIP funding from 2005 to 2010.
- **Wildlife Habitat Incentive Program (WHIP):** The WHIP is a voluntary program that assists private landowners in developing and improving wildlife habitat on agricultural land, nonindustrial private forest land, and Tribal lands. The seven Missouri River basin states averaged a total of \$17.5 million annually in WHIP funding from 2005 to 2010.

NPS Missouri National Recreational River Management Actions: The MNRR, located on the border between Nebraska and South Dakota, represents the majority of land managed by the NPS on the Missouri River. Although there has been development along the Missouri River within the national park, it is one of the few remaining segments that still exhibit some characteristics of a natural undammed and unchannelized river. To ensure this in the future, NPS staff continually monitor changes in environmental factors and implement plans and actions to preserve and protect natural resources. A general management plan and environmental impact statement for the lower 59-mile reach was issued in 1999, and for the upper 39-mile stretch was issued in 1997, which was meant to provide guidance for 10–15 years. Approximately 70,000 acres are included between the two reaches. MNRR management includes active preservation and restoration of native vegetation on roughly 300 acres. Habitat creation within the Missouri River floodplain includes two cottonwood regeneration projects near Bow Creek. Wetland creation along the MNRR is primarily through the NRCS Wetlands Reserve Enhancement Program and WRP. The MNRR includes management strategies to directly benefit both the endangered least tern and piping plover.

EPA Section 319 Non-Point Source Grant Program: The mission of the EPA is to protect human health and the environment. EPA administers regulatory and voluntary grant programs under the Clean Water Act (CWA) that contribute to mitigation, recovery, and restoration on the landscape/watershed scale. The passage and implementation of the CWA established a regulatory framework that resulted in considerable improvement in the nation's water quality. The Section 319 Non-Point Source Grant Program under the CWA provides grant money to states and Tribes to support nonpoint source control projects. A wide variety of support is provided under this program including technical assistance, financial assistance, education, training, technology transfer, demonstration projects, watershed planning, implementation of best management practices and monitoring. Specific project actions include:

- Total Maximum Daily Load establishment and monitoring
- Best Management Practice design and implementation
- Wetland restoration/protection

- Nutrient runoff management
- Water quality assessment and monitoring
- Stormwater discharge control
- Vegetation management
- Erosion control
- Streambank stabilization

From 2007 to 2011 the seven mainstem states received a total yearly average of \$14.1 million in Section 319(h) grant funding.

Tribal Programs and Actions: The Tribes along the Missouri River are involved with natural resources management and several tribes are involved with the management of federally listed species. As an example, the Cheyenne River Sioux Tribe is involved with the management of federally listed species through their involvement with monitoring terns and plovers on the Missouri and Cheyenne Rivers (USFWS 2000). The Cheyenne River Sioux Tribe and the Lower Brule Sioux Tribe have also developed terrestrial mitigation projects under Title VI – Cheyenne River Sioux Tribe, Lower Brule Sioux Tribe, and State of South Dakota Terrestrial Wildlife Habitat Restoration (PL 105-277) and WRDA of 1999 (PL 106-53). The Cheyenne River Sioux and Lower Brule Sioux Tribes have designed their mitigation efforts to restore riparian, ecological, and cultural significance to their land adjacent to the Missouri River. Example projects on the Cheyenne River reservation include planting cottonwood saplings along the shoreline to mitigate for loss of cottonwood forests due to the impoundment of Lake Oahe, wetland restoration along Medicine Creek, and construction of an island to protect a cultural site and to provide an area for native tree, shrub, and prairie grass plantings.

Comprehensive Wildlife Conservation Plans and Protected Natural Areas (all states): Each state along the Mainstem Missouri River implements a comprehensive fish and wildlife habitat management plan (CWMP) that, at a programmatic level, serves to synthesize information on wildlife species, habitats, threats, conservation priorities and opportunities (Storms et al. 2008). The plans emphasize ecosystems and species of greatest conservation need. In the majority of states, the CWMPs represent an increased emphasis on conserving non-game species. The CWMPs also serve to identify priority conservation areas; each mainstem state identifies portions of the Missouri River as a high priority for conservation.

Yellowstone Intake Diversion Dam Modification: The goal of the Yellowstone Intake Diversion Dam modification is to improve passage for the endangered pallid sturgeon and other native fish and to reduce entrainment of fish into the main channel of the Lower Yellowstone Project. The implementation timeline for this project is currently uncertain due to ongoing litigation.

Intentionally Left Blank

APPENDIX D: HYDROLOGIC PERIOD OF RECORD ANALYSIS OF ALTERNATIVES

Intentionally Left Blank

Appendix D: Hydrologic Period of Record Analysis of Alternatives

This appendix provides the graphics of the overall long-term hydrology in the river and reservoirs based on the period of record (POR). The POR consists of average measurements of stage (or elevation) and flow for each day over 82 years between 1931 and 2012¹. The analysis evaluates key locations along the Missouri River, as well as for St. Louis at the Mississippi River downstream of the confluence with the Missouri River (Figure D-1).

General hydrologic conditions in the river and its reservoirs were analyzed using the statistical 90th, 50th, and 10th percentiles simulated for flow conditions of the 82-year POR for the six alternatives. It is noted that flows and stages presented in this analysis are not observed data. All simulated results are corrected to reflect the 2012 level of water development, commonly referred to as depletions. Depletions to streamflow result from evaporation on System and tributary reservoirs, irrigation, implementation of Tribal water rights, conservation practices in the basin, and development of the multitude of stock and farm ponds. Reservoir stages and releases are from model simulations using the depletion corrected inflow. Therefore, while the flows and stages determined for alternatives can be compared to each other, it is not possible to compare to observed data.

A percentile is a statistical measure indicating the value below which a given percentage of observations in a group of observations falls. For example, the 90th percentile of a reservoir elevation reflects the elevation below which 90 percent of the elevations may be found; only 10 percent of the elevations would be higher. Thus, the 90th percentile may be indicative of “wet period” conditions. A “period” could be a year or several years long, affecting storage and flow conditions. Similarly, the 10th percentile is the reservoir elevation below which 10 percent of the elevations may be found; 90 percent of the elevations would be higher. Thus, the 10th percentile may be indicative of “dry period” conditions. Finally, the 50th percentile of the reservoir elevation may be indicative of “average” conditions, where 50 percent of the elevations are higher and 50 percent of the elevations are lower. Similar definitions also apply to percentiles used for flow and stage in the river.

Impacts under wet, average, and dry period conditions (90th, 50th, and 10th percentile, respectively) are presented together for the six alternatives to demonstrate similarities and differences. However, hydrological conditions during individual years can result in specific changes under individual alternatives. For example, during extreme droughts such as in the 1930s and during peak flow events such as the spring and summer of 2011, rules would prevent flow releases under Alternatives 1, 2, 4, 5, and 6 to avoid a potential worsening of the effects of these extreme conditions.

Presented figures with percentile summaries superimpose all six alternatives; these figures include the following:

- Percentiles of the elevations for the upper four reservoirs (Figures D-2 to D-5).

¹ It is noted that the analysis is limited to an 82-year period of record. Consequently, the number of years with flow conditions that would trigger releases under the various action alternatives is limited and statistically small. The limited data set necessitates monitoring of impacts and adaptive management under any implemented action alternative.

- Percentiles of stage and flow, as well as maximum flows, at Bismarck, North Dakota (Figures D-6 to D-8).
- Percentiles of flow at Gavins Point Dam, South Dakota; Sioux City, Iowa; Omaha, Nebraska; Nebraska City, Nebraska; and Kansas City, Missouri (Figures D-9 to D-13).
- Percentiles of stage at Sioux City, Iowa; Omaha, Nebraska; Nebraska City, Nebraska; and Kansas City, Missouri (Figures D-14 to D-17).
- Percentiles of flow, as well as maximum and minimum flow at St. Louis, Missouri, downstream of the confluence with the Missouri River.

For the Missouri River, the analysis of Figures D-2 to D-17 is provided in Section 3.2.2.3, Impacts on Hydrology from the Alternatives. For the Mississippi River (St. Louis Station), the analysis of Figure D-18 and D-19 is provided in Section 3.24, Mississippi River Impacts.

None of the proposed management actions would change the total volume of water transported through the river System over the long term. However, the timing of flow releases and flow rates would be altered and some dominant peak flows may be introduced by high releases, which would affect geomorphological processes in the river, groundwater elevations, and riverine infrastructure. Similarly, the overall fluctuations in elevation in the upper three reservoirs are dominated by natural precipitation and snow melt patterns. However, flow releases under the proposed action would add fluctuations in the reservoir elevations; these added fluctuations could increase shoreline erosion as a result of the wetting and drying cycle.

Future Conditions

The statistical analyses in Figures D-2 to D-17 pertain to “Year 0.” Year 0 reflects conditions based on (1) the current storage volume in the six reservoirs along the upper Missouri River and (2) the current geometry of the Missouri River riverbed. Over time, these two variables will continue to change as follows: Continued sediment supply over time will gradually reduce the storage volume in the reservoirs of the upper Missouri River, and continue to cause aggradation in the reservoir headwaters and delta. Sediment captured by the reservoirs will continue to degrade the riverbed in respective downstream reaches. In addition, sand and aggregate mining in the lower Missouri River is expected to continue degrading the riverbed.

In order to account for future reservoir sediment accumulation and riverbed degradation, flows and stage/elevation for the six alternatives were also modeled for “Year 15.” Year 15 reflects conditions that are expected to exist after 15 years of operating a specific alternative. These conditions integrate continued reservoir storage loss and aggradation in the reservoir deltas as well as degradation of the riverbed from sediment capture by the reservoirs and from sand and gravel mining at currently projected rates of extraction.

Inflows in Year 15 would be the same as in Year 0. However, some flow changes would occur because of the way HEC-ResSim operates the System with different storage volumes to meet the requirements specified in the Master Manual (USACE 2006a). The mean flow release at Gavins Point Dam in Year 15 are projected to decrease by less than 70 cfs (0.03 percent) under the six alternatives compared to flows in Year 0 (Figure D-20). However, elevations in the

reservoirs and stages in the river would change in Year 15. Figures D-21 to D-30 present a comparison of elevations and stages under Year 0 and Year 15 for select locations as follows:²

- Elevations in the upper three reservoirs along the Missouri River (Figures D-21 to D-23)
- Stages at Bismarck, North Dakota (Figure D-24)
- Stages at Sioux City, Iowa; Omaha, Nebraska; St. Joseph, Missouri; and Kansas City, Missouri (Figures D-25 to D-29).
- Stages in the Mississippi River at St. Louis, Missouri, downstream of the confluence with the Missouri River (Figure D-30).

For the Missouri River, the analysis of Figures D-21 to D-29 is provided in Section 3.2.2.3, Impacts on Hydrology from the Alternatives. For the Mississippi River (St. Louis Station), the analysis of Figure D-30 is provided in Section 3.24, Mississippi River Impacts. In summary, the elevations and stages are projected to change as follows between Year 0 and Year 15:

- **Upper three reservoirs:** Elevations in the upper three reservoirs (Fort Peck Lake, Lake Sakakawea, Lake Oahe) would increase slightly (Figures D-21 to D-23). The mean elevation in the three upper reservoirs would be 1 to 2 feet higher under the six alternatives throughout the year in Year 15 as compared to Year 0. This is reflected, for example, by average period (50th percentile) elevations for the three reservoirs under the No Action alternative (Figure 3-8 in the main report); 50th percentile elevations for the other five alternatives would be similar. However, reservoir releases prior to drought years could result in higher minimum elevations (up to 20 feet) in each of the three upper reservoirs in subsequent years due to drought conservation measures (e.g., reducing service levels) being triggered earlier.
- **Lower three reservoirs:** Changes in elevations in the lower three reservoirs (Lake Sharpe, Lake Francis Case, Lewis and Clark Lake) from Year 0 to Year 15 would be negligible.
- **Upper Missouri River, Bismarck, North Dakota:** The stages in Bismarck would be slightly lower (mean of approximately 4 inches) in Year 15 under the six alternatives due to minor degradation (Figure D-24).
- **Lower Missouri River, Gavins Point Dam to Rulo, Nebraska:** In the upper portion of the lower Missouri River (Gavins Point Dam to Rulo, Nebraska), continued degradation of the riverbed due to sediment captured by the reservoirs would lower the stages slightly in Year 15 compared to Year 0. For example, the mean decrease in Year 15 as compared to Year 0 would be approximately 0.5 foot both at Sioux City, Iowa, and at Omaha, Nebraska (Figures D-25 and D-26). This decrease in stage would typically be consistent throughout the year, as shown for example by the 50th percentile stages for Years 0 and 15 under the No Action alternative (Figure 3-9 in the main report); 50th percentile stages for the other five alternatives would be similar. However, flow release

² The data on these figures are shown as box plots. The diamond in the center of each box represents the mean; the horizontal line within each box represents the median; the colored range of each box represents the 5th and 95th percentiles; and the extreme endpoints of the lines outside of each box represent the minimum and maximum values.

alterations during drought year periods (such as 1930s) could result in larger decreases in stages of the lower river.

- **Lower Missouri River, Rulo, Nebraska, to St. Louis, Missouri:** The residual degradation effect of sediment captured by the reservoirs combines with degradation from sand and aggregate mining in the lower reach of the lower Missouri River between Rulo, Nebraska, and the confluence with the Mississippi River in St. Louis, Missouri. Rates of degradation in this reach are variable because of several factors, including projected amount of sediment to be mined, response of the river channel to changes in mining volumes over time, sediment contributions from larger tributaries such as the Kansas River, and responses of the riverbed due to peak flow events.

Using assumptions based on currently available information and reasonable forecasts, HEC-RAS modeling predicted a decrease in the mean stage at St. Joseph, Missouri, by approximately 2.5 feet for the six alternatives in Year 15 compared to Year 0 (Figure D-27). In Kansas City, just downstream of the confluence with the Kansas River, the projected mean stage in Year 15 would only be slightly lower (approximately one inch) compared to Year 0 (Figure D-28). The reason for the comparatively small decrease in Kansas City is contributed to reduced sand and aggregate mining rates in recent years that has led to some recovery of the riverbed elevations, and due to sediment carried into the Missouri River from degrading reaches upstream and by the Kansas River. Longer-term, however, if sand and aggregate mining continues at current rates in the vicinity of Kansas City, degradation rates of the riverbed in this reach could increase again.

As for the reach of the lower Missouri River between Gavins Point Dam to Rulo, Nebraska, the decrease in stage downstream of Rulo is typically consistent throughout the year, as shown for example by the 50th percentile stages for the No Action alternative (Figure 3-9 in the main report); 50th percentile stages for the other alternatives would be similar. Exceptions would also be drought-related flow reductions that could result in decreases in stage by up to 10 feet in St. Joseph, Missouri, and up to 6 feet in Kansas City for several months in Year 15 as compared to Year 0.

At Hermann, Missouri, the mean stage in Year 15 would be lower by approximately 0.5 foot for the six alternatives (Figure D-29). While the lower stage would be consistent throughout the year, drought-related reductions in flow could result in decreases in stage by up to 5 feet for several months in Year 15 as compared to Year 0.

Figure D-29. Comparison of Stages between Year 0 and Year 15 for Hermann, Missouri, under Alternatives 1 to 6 over the Period of Record (mean, median, and 5th and 95th percentiles)

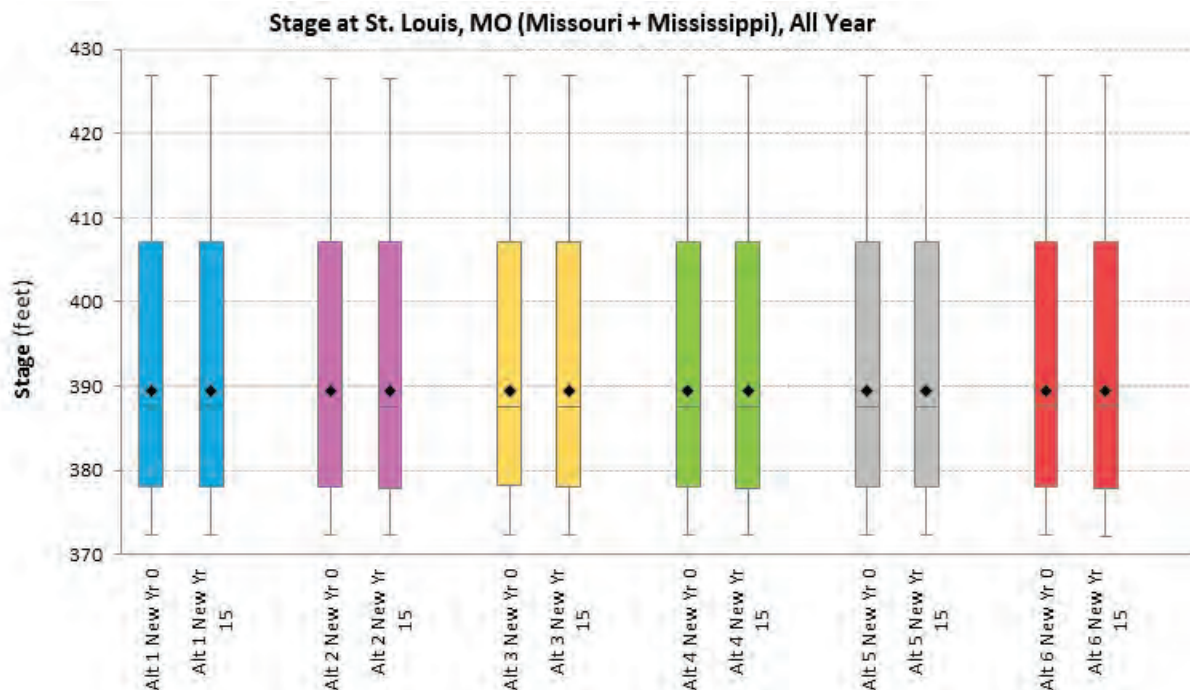

Figure D-30. Comparison of Stages between Year 0 and Year 15 for the Mississippi River (downstream of the confluence with the Missouri River) at St. Louis under Alternatives 1 to 6 over the Period of Record (mean, median, and 5th and 95th percentiles)

APPENDIX E: OTHER SPECIAL-STATUS SPECIES

Intentionally Left Blank

Appendix E: Other Special-Status Species

Table E-1 lists other special status species known to occur or may occur within the geographic scope of the EIS. Each species is listed by common name and scientific name along with their federal and state statuses. Habitat associations and river reaches in which each species holds a special status designation are provided along with anticipated impacts under each alternative. Impacts are not expected to differ significantly among alternatives. All of the alternatives are expected to have long-term beneficial impacts on fish and wildlife from the addition of lost terrestrial and aquatic habitat. Adverse impacts would primarily consist of short-term construction related impacts. Additional environmental analyses will be completed for site-specific management actions before they are implemented.

The criteria for identifying species and how these species are organized vary from state to state. A description of how each state designates and classifies special status species is provided below.

Montana

Montana does not have a state endangered or threatened species list. However, the Montana Natural Heritage Program maintains a list of Species of Concern for native animals and plants that are considered to be "at risk" due to declining population trends, threats to their habitats, and/or restricted distribution (MTNHP 2016a, 2016b). Designation as a Species of Concern is not a statutory or regulatory classification. Conservation measures for many Montana species of concern are outlined in the State Wildlife Action Plan (MDFWP 2015).

Montana uses a standardized ranking system employed by the international network of natural heritage programs to denote state status for Species of Concern. Species are assigned numeric ranks ranging from 1 (highest risk, greatest concern) to 5 (demonstrably secure, least concern), reflecting the relative degree of risk to the species viability, based upon available information (MTNHP 2016b). "S" indicates that the ranking is at the state level (as opposed to global rankings), "B" indicates that the ranking applies only to breeding populations, "M" indicates that the species is only present in Montana during migrations, and "H" denotes historical populations. One species (red knot) has a ranking of "SNA," which indicates that a state rank is not applicable, because of a lack of information on its migratory stopover use of Montana wetlands. However it is still considered a special status species in Montana due its federal status under ESA.

North Dakota

North Dakota does not have a state endangered or threatened species list. Only those species listed by the ESA are considered threatened or endangered in North Dakota. North Dakota has a Wildlife Action Plan that focuses on species that are considered species of conservation priority. Information relating to the distribution, abundance, habitat requirements, threats, management goals and monitoring techniques for each of these species is included in the Wildlife Action Plan (NDGF 2016). The species are categorized into three levels as described below.

- **Level I:** These species are in decline and receive little or no monetary support or conservation efforts. North Dakota Game and Fish Department has a clear obligation to use state wildlife grants funding to implement conservation actions that directly

benefit these species. Level I species have a high level of conservation priority because of declining status across their range or high rate of occurrence in North Dakota constituting the core of the species breeding range.

- **Level II:** North Dakota Game and Fish Department will use state wildlife grants to implement conservation actions to benefit these species if funding for Level I species is sufficient or conservation needs have been met. Level II species have a moderate level of conservation priority or high level of conservation priority but a substantial level of non-state funding available to them
- **Level III:** These are North Dakota species having a moderate level of conservation priority but are believed to be peripheral or nonbreeding in North Dakota (NDGF 2016).

South Dakota

The South Dakota Game, Fish and Parks maintains a list of state-designated threatened and endangered species which are separate from federally-listed species. This list is reviewed and updated biannually. State-level designations for threatened and endangered species are also used to identify species in need of state wildlife grants funding (SDFGP 2016). Conservation measures for South Dakota state-listed species are outlined in the state wildlife action plan (SDDGFP 2014).

Nebraska

Nebraska Game and Parks maintains a list of state-designated threatened and endangered species in accordance with the Nebraska Nongame and Endangered Species Conservation Act (NGPC 2015). These species are separate from federally-listed species and represent a subset of species determined to be “at-risk” in Nebraska. Animals and plants are designated as endangered or threatened when their continued existence in Nebraska is in jeopardy. The Nebraska Game and Parks Commission develops state recovery plans which set forth measures to restore populations of these animals and plants to a more secure status (NGPC 2015). Conservation measures for state-listed species are also outlined in the Nebraska state wildlife action plan, developed in partnership with the Nebraska Natural Legacy Program (Schneider et al. 2011).

Iowa

Iowa maintains a list of state-designated threatened and endangered species, which are separate from federally listed species. Species are designated by the Iowa Department of Natural Resources, in accordance with Chapter 481B of the Iowa Administrative Code: Endangered Plants and Wildlife. The designation of endangered is given to any species of fish, plant life, or wildlife in danger of extinction throughout all or a significant part of its range. The designation of threatened is given to any species which is likely to become an endangered species within the foreseeable future throughout all or a significant portion of its range, and both designations are protected by law (IAC 2009). Additionally, the Iowa Wildlife Action Plan is a 25-year proactive strategy designed to facilitate recovery of listed species and conserve other wildlife species in Iowa, before special status designations become necessary (IDNR 2015).

Kansas

The Kansas Department of Wildlife, Parks and Tourism maintains a list of state-level threatened and endangered species in accordance with the Kansas Nongame and Endangered Species Conservation Act of 1975 (KWPT 2015). State-designated threatened and endangered species statuses are reviewed on five-year intervals and recovery plans are developed to facilitate recovery of listed species. The Kansas Wildlife Action Plan also outlines measures to conserve state-listed species and is used to appropriately allocate conservation funding (Rohweder 2015).

Missouri

The Missouri Department of Conservation maintains a list of state-designated threatened and endangered species in accordance with the Missouri State Endangered Species Law 252.240 (MDC 2018). Conservation measures for state-listed species are also outlined in the Missouri State Wildlife Action Plan (MDC 2015).

Table E-1. Adverse Impacts of Alternatives 1–6 on Other Special Status Species

R1 = Fort Peck Lake to Garrison Dam; R2 = Garrison Dam to Oahe Lake; R3 = Fort Randall Dam to Gavins Point Dam; R4 = Gavins Point Dam to Rulo;
 R5 = Rulo to Kansas River; R6 = Kansas River to Grand River; R7 = Grand River to Osage River; R8 = Osage River to Mississippi River

Assumptions applicable to all Management Actions

- | | | |
|---|-----|---|
| 1. All costs and benefits are in FY2018 (1st Quarter 2018) dollars, are unescalated beyond that and are not discounted to generate a Net Present Value. | | |
| 2. Where cost data was dated before the 4th quarter of 2015, it was escalated using the Engineering Manual on the Civil Works Construction Cost Index System (CWCCIS). The indices for Line 06 Fish & Wildlife Facilities were used to escalate costs as necessary. | | |
| 3. Various "soft costs" have been added to the construction costs to arrive at a total project cost, where applicable. These are typically as follows: | | |
| a) Project Management (PM) | 5% | |
| b) Pre-construction Engineering & Design (PED) | 10% | |
| c) Supervision & Administration (S&A) | 6% | |
| d) Operations, Maintenance, Repair, Rehabilitation & Replacement (OMRRR) | 20% | Note - doesn't apply to sandbar projects. |
| e) Operations & Maintenance (O&M) - only applies to channel widening and backwater construction projects and was developed on a cost/acre basis from information provided by USACE. | | |
| f) Engineering during construction (EDC) | 5% | |
| g) Contingency | 20% | |
| 4. As construction durations are presently unknown, no allowance has been included for interest costs incurred during construction. | | |

Intentionally Left Blank

Alternative Summary		Alternative 1 - No Action	Assumptions for estimates
Management Actions		TOTAL	
Operations & Maintenance (O&M) Costs			
Early Life Stage Habitat O&M:			
Existing SWH operations & maintenance	392,653,049	O&M cost of \$4,903/acre (escalated to 1st Q 2018) for existing 1,509 acres (744 acres of chutes and 366 acres of backwaters for Omaha; 399 acres of chutes for Kansas City) - assumes same cost as top width O&M. Costs are escalated to 1st Q 2018.	
Channel Widening - total O&M	915,670,032	Total for Omaha & Kansas City	
- Omaha reaches O&M costs	378,081,431	O&M - cost for O&M spread over 50 years (at \$4,893/acre, escalated to 1st Q 2018).	
- Kansas City reaches O&M costs	537,588,601		
Backwater - OMRRR	80,735,837	OMRRR spread over 50 years (at \$3,184/acre for 480 acres, escalated to 1st Q 2018)	
Total Habitat O&M Cost	1,389,058,918		
Construction General (CG) Costs			
Program Management, Integration & Coordination	300,582,937	\$5,690,000 annually (per USACE), for 50 years, escalated to 1st Q, 2018.	
MRRIC	94,850,000	\$1,897,000 annually (per USACE), for 50 years.	
Lower River Pallid Sturgeon			
Propagation and Augmentation Program	23,977,588	Annual budget of \$455,167 for 50 years, escalated to 1st Q, 2018.	
Spawning Habitat Construction	N/A		
Early Life Stage Habitat Construction:			
- Omaha reaches construction	248,204,641	Construction - cost of 3,519 acres at \$115,800 for Omaha acreage; \$243,614 for Kansas City acreage (average cost data escalated to 10/15) plus applicable mark-ups, assuming 100% material removal, spread over 15 years. Costs/acre include PED, and are escalated to 1st Q 2018.	
- Kansas City reaches construction	742,450,531		
- Backwater - construction	66,901,575	Cost of 480 acres at \$86,844 plus applicable mark-ups (escalated to 1st Q, 2018), spread over 15 years	
Total Habitat Construction Cost	1,057,556,747		
Real Estate Acquisition	41,227,347	Acquisition cost of 915 acres x 7.7 = 7,046 acres. Acquisition cost based on a weighted average of costs of agricultural land and recreational land. For Omaha Reach, using ag. land price of \$6,000/acre and rec. land at \$2,000/acre, with a 60/40 split, resulting in an average of \$4,400/acre. For KC Reach ag. land at \$5,050 and rec. land at \$3,261, with an 80/20 split, resulting in an average cost of \$4,692/acre. Assumed to be purchased over a 10-year period, with a 20% contingency applied (all costs escalated to 1st Q, 2018)	
Habitat Development	8,177,861	5,267 acres of agricultural land developed over 15 years at a cost of \$1,500 per acre, escalated to 1st Q, 2018.	
Land Management	7,729,427	6,131 acres managed over a 50-year period at an annual cost of \$29/acre, escalated to 1st Q 2018.	
Spawning Cue Flow	No implementation cost		
Low Summer Flow	N/A		
Floodplain Connectivity	N/A

Alternative Summary		Alternative 3 - Pallid Habitat Construction & ESH Mechanical TOTAL	Assumptions for estimates
Management Actions			
Spawning Habitat OMRRR	1,252,696	Cost of OMRRR for 6.6 acres (3 sites at 2.2 acres each), at 20% of construction cost; annually for 50 years	
<u>Early Life Stage Habitat O&M:</u>			
Existing SWH operations & maintenance	392,653,049	O&M cost of \$4,903/acre (escalated to 1st Q 2018) for existing 1,509 acres (744 acres of chutes and 366 acres of backwaters for Omaha; 399 acres of chutes for Kansas City) - assumes same cost as top width O&M. Costs are escalated to 1st Q 2018.	
Channel Widening - total O&M	52,301,698	Total for Omaha & Kansas City	
- Omaha reaches O&M costs	52,301,698	O&M - cost for O&M spread over 50 years (at \$4,893/acre); for the 10 structure modifications projects in KC reaches, \$114,500 is included per year. Costs are escalated to 1st Q 2018.	
- Kansas City reaches O&M costs	151,180,967		
Total Habitat O&M Cost	444,954,747		
Construction General (CG) Costs			
Program Management, Integration & Coordination	300,582,937	\$5,690,000 annually (per USACE), for 50 years, escalated to 1st Q, 2018.	
MRRIC	94,850,000	\$1,897,000 annually (per USACE), for 50 years.	
Lower River Pallid Sturgeon			
Propagation and Augmentation Program	23,977,588	Annual budget of \$455,167 for 50 years, escalated to 1st Q, 2018.	
Spawning Habitat Construction	1,127,426	Cost of creation of 6.6 acres (3 sites at 2.2 acres each), starting in year 3 and spread over 9 years, using the Omaha cost/acre for channel widening of \$115,800 (escalated to 1st Q 2018).	
SWH Refurbishment - total	48,406,594		
- Omaha	24,203,297	Construction of 22 chute projects yielding 60 acres each, split evenly between Omaha & Kansas City. Cost is based on average of the estimated first cost of Baltimore and Searcy Bends, escalated to 1st Q 2018.	
- Kansas City	24,203,297		
<u>Early Life Stage Habitat Construction:</u>			
- Omaha reaches construction	34,335,260	Construction - cost of 201 acres at \$115,800 for Omaha acreage; 559 acres at \$243,614 for Kansas City acreage plus applicable mark-ups, assuming 100% material removal, spread over 15 years. Costs/acre include PED. Note 1,300 acres in KC reaches is for 10 structure modification projects, constructed in years 3 - 7. Costs included for that acreage are \$1,970,235 for construction, plus escalation to 1st Q 2018.	
- Kansas City reaches construction	222,888,693		
- Backwater - construction	Not required		
Total Habitat Construction Cost	257,223,953		
Real Estate Acquisition	10,541,078	Cost of acquisition of 230 acres x 7.7 = 1,772 acres. Acquisition cost based on a weighted average of costs of agricultural land and recreational land. For KC Reach ag. land at \$5,050 and rec. land at \$3,261, with an 80/20 split, resulting in an average cost of \$4,692/acre. Assumed to be purchased over a 10-year period, with a 20% contingency applied (all costs escalated to 1st Q, 2018).	
Habitat Development	2,199,725	1,417 acres of agricultural land developed over 15 years at a cost of \$1,500 per acre, escalated to 1st Q 2018.	
Land Management	1,942,758	1,541 acres managed over a 50-year period at an annual cost of \$29/acre, escalated to 1st Q, 2018.

Alternative Summary		Alternative 4 - Pallid Habitat Construction and ESH Spring Release TOTAL	Assumptions for estimates
Management Actions			
Operations & Maintenance (O&M) Costs			
Spawning Habitat OMRRR	1,252,696	Cost of OMRRR for 6.6 acres (3 sites at 2.2 acres each), at 20% of construction cost; annually for 50 years	
Early Life Stage Habitat O&M:			
Existing SWH operations & maintenance	392,653,049	O&M cost of \$4,903/acre (escalated to 1st Q 2018) for existing 1,509 acres (744 acres of chutes and 366 acres of backwaters for Omaha; 399 acres of chutes for Kansas City) - assumes same cost as top width O&M. Costs are escalated to 1st Q 2018.	
Channel Widening - total O&M	203,482,665	Total for Omaha & Kansas City	
- Omaha reaches O&M costs	52,301,698	O&M - cost for O&M spread over 50 years (at \$4,893/acre); for the 10 structure modifications projects in KC reaches, \$114,500 is included per year. Costs are escalated to 1st Q 2018.	
- Kansas City reaches O&M costs	151,180,967		
Total Habitat O&M Cost	596,135,714		
Construction General (CG) Costs			
Program Management, Integration & Coordination	300,582,937	\$5,690,000 annually (per USACE), for 50 years, escalated to 1st Q, 2018.	
MRRIC	94,850,000	\$1,897,000 annually (per USACE), for 50 years.	
Lower River Pallid Sturgeon			
Propagation and Augmentation Program	23,977,588	Annual budget of \$455,167 for 50 years, escalated to 1st Q, 2018.	
Spawning Habitat Construction	1,127,426	Cost of creation of 6.6 acres (3 sites at 2.2 acres each), starting in year 3 and spread over 9 years, using the Omaha cost/acre for channel widening of \$115,800 (escalated to 1st Q 2018).	
SWH Refurbishment - total	48,406,594		
- Omaha	24,203,297	Construction of 22 chute projects yielding 60 acres each, split evenly between Omaha & Kansas City. Cost is based on average of the estimated first cost of Baltimore and Searcy Bends, escalated to 1st Q 2018.	
- Kansas City	24,203,297		
Early Life Stage Habitat Construction:			
- Omaha reaches construction	34,335,260	Construction - cost of 201 acres at \$115,800 for Omaha acreage; 559 acres at \$243,614 for Kansas City acreage plus applicable mark-ups, assuming 100% material removal, spread over 15 years. Costs/acre include PED. Note 1,300 acres in KC reaches is for 10 structure modification projects, constructed in years 3 - 7. Costs included for that acreage are \$1,970,235 for construction, plus escalation to 1st Q 2018.	
- Kansas City reaches construction	222,888,693		
- Backwater - construction	Not required		
Total Habitat Construction Cost	257,223,953		
Real Estate Acquisition	10,541,078	Cost of acquisition of 230 acres x 7.7 = 1,772 acres. Acquisition cost based on a weighted average of costs of agricultural land and recreational land. For KC Reach ag. land at \$5,050 and rec. land at \$3,261, with an 80/20 split, resulting in an average cost of \$4,692/acre. Assumed to be purchased over a 10-year period, with a 20% contingency applied (all costs escalated to 1st Q, 2018).	
Habitat Development	2,199,725	1,417 acres of agricultural land developed over 15 years at a cost of \$1,500 per acre, escalated to 1st Q 2018.	
Land Management	1,942,758	1,541 acres managed over a 50-year period at an annual cost of \$29/acre, escalated to 1st Q, 2018.

Alternative 3 - Pallid Habitat Construction and ESH Fall Release TOTAL		Assumptions for estimates
Alternative Summary Management Actions		
Operations & Maintenance (O&M) Costs		
Spawning Habitat OMRRR	1,252,696	Cost of OMRRR for 6.6 acres (3 sites at 2.2 acres each), at 20% of construction cost; annually for 50 years
Early Life Stage Habitat O&M:		
Existing SWH operations & maintenance	392,653,049	O&M cost of \$4,903/acre (escalated to 1st Q 2018) for existing 1,509 acres (744 acres of chutes and 366 acres of backwaters for Omaha; 399 acres of chutes for Kansas City) - assumes same cost as top width O&M. Costs are escalated to 1st Q 2018.
Channel Widening - total O&M	203,482,665	Total for Omaha & Kansas City
- Omaha reaches O&M costs	52,301,698	O&M - cost for O&M spread over 50 years (at \$4,893/acre); for the 10 structure modifications projects in KC reaches, \$114,500 is included per year. Costs are escalated to 1st Q 2018.
- Kansas City reaches O&M costs	151,180,967	
Total Habitat O&M Cost	596,135,714	
Construction General (CG) Costs		
Program Management, Integration & Coordination	300,582,937	\$5,690,000 annually (per USACE), for 50 years, escalated to 1st Q, 2018.
MRRIC	94,850,000	\$1,897,000 annually (per USACE), for 50 years.
Lower River Pallid Sturgeon		
Propagation and Augmentation Program	23,977,588	Annual budget of \$455,167 for 50 years, escalated to 1st Q, 2018.
Spawning Habitat Construction	1,127,426	Cost of creation of 6.6 acres (3 sites at 2.2 acres each), starting in year 3 and spread over 9 years, using the Omaha cost/acre for channel widening of \$115,800 (escalated to 1st Q 2018).
SWH Refurbishment - total	48,406,594	
- Omaha	24,203,297	Construction of 22 chute projects yielding 60 acres each, split evenly between Omaha & Kansas City. Cost is based on average of the estimated first cost of Baltimore and Searcy Bends, escalated to 1st Q 2018.
- Kansas City	24,203,297	
Early Life Stage Habitat Construction:		
- Omaha reaches construction	34,335,260	Construction - cost of 201 acres at \$115,800 for Omaha acreage; 559 acres at \$243,614 for Kansas City acreage plus applicable mark-ups, assuming 100% material removal, spread over 15 years. Costs/acre include PED. Note 1,300 acres in KC reaches is for 10 structure modification projects, constructed in years 3 - 7. Costs included for that acreage are \$1,970,235 for construction, plus escalation to 1st Q 2018.
- Kansas City reaches construction	222,888,693	
- Backwater - construction	Not required	
Total Habitat Construction Cost	257,223,953	
Real Estate Acquisition	10,541,078	Cost of acquisition of 230 acres x 7.7 = 1,772 acres. Acquisition cost based on a weighted average of costs of agricultural land and recreational land. For KC Reach ag. land at \$5,050 and rec. land at \$3,261, with an 80/20 split, resulting in an average cost of \$4,692/acre. Assumed to be purchased over a 10-year period, with a 20% contingency applied (all costs escalated to 1st Q, 2018).
Habitat Development	2,199,725	1,417 acres of agricultural land developed over 15 years at a cost of \$1,500 per acre, escalated to 1st Q 2018.
Land Management	1,942,758	1,541 acres managed over a 50-year period at an annual cost of \$29/acre, escalated to 1st Q, 2018.
Spawning Cue Flow	N/A	
Low Summer Flow	N/A	
Floodplain Connectivity	N/A	
Monitoring, Evaluation and Research:		
PSPAP	129,383,439	\$2,500,000 annually for 50 years, escalated to 1st Q 2018.
HAMP	28,883,554	\$1,860,333 annually for 15 years, escalated to 1st Q 2018.
Focused Research	N/A	
Level 1 and 2 studies	28,468,865	Annual cost of \$1,422,171 for 19 years - based on total cost of \$27,021,250 for years 2014 - 2032, converted to an average annual cost (escalated to 1st Q 2018).

APPENDIX G: MRRIC RECOMMENDATIONS

Intentionally Left Blank

Approved February 7, 2012
Transmitted February 21, 2012

Mr. David Ponganis
Acting Director of Programs
US Army Corps of Engineers
Northwestern Division
P.O. Box 2870
Portland, OR 97208-2870

Mr. Stephen Guertin
Regional Director
U.S. Fish and Wildlife Service, Region 6
P.O. Box 25486 – DFC
Denver, CO 80225-0486

Dear Mr. Ponganis & Director Guertin

I am writing you on behalf of the Missouri River Recovery Implementation Committee (MRRIC or the Committee). The MRRIC has nearly 70 members comprised of States, Tribes, Federal Agencies, and Stakeholders associated with Missouri River resources. It was authorized by Congress in Section 5018 of the Water Resources Development Act of 2007 and established in 2008 by the Assistant Secretary of the Army for Civil Works (Secretary). The duties of this committee include providing guidance to the Secretary regarding the existing Missouri River recovery and mitigation plans, including recommendations on the annual work plan and budget.

I am pleased to provide you with MRRIC's initial recommendation on the Final Report provided by the Independent Science Advisory Panel (ISAP) on Spring Pulses and Adaptive Management reached by consensus of MRRIC members present during our meeting in Kansas City, MO, on February 7-9, 2012. The recommendation is as follows:

Following a collaborative effort, between the SAM Work Group and the lead agencies, to review the ISAP Final Report #1 and consider next steps – the Lead Agencies will provide a written response(s) to MRRIC regarding the findings/recommendations in the ISAP Final Report on Topic #1. The SAM Work Group will review the agency response(s) and ISAP Final Report on Topic #1, and assess whether to develop additional recommendations for MRRIC consideration.

Thank you for your consideration of this recommendation. Please contact me if you have any questions.

Sincerely,

A handwritten signature in black ink that reads "Michael J. Mac". The signature is fluid and cursive, with the first name "Michael" and last name "Mac" clearly legible.

Michael J. Mac

Northwestern Division
US Army Corps of Engineers

Subject: MRRIC Recommendations for Proposed Actions to Move Forward Fulfillment of the
ISAP Final Report on Spring Pulses and Adaptive Management

Dear Mr. Ponganis:

I am writing you on behalf of the Missouri River Recovery Implementation Committee (MRRIC or the Committee). The MRRIC has nearly 70 members comprised of States, Tribes, Federal Agencies, and Stakeholders associated with Missouri River. It was authorized by Congress in Section 5018 of the Water Resources Development Act of 2007 and established in 2008 by the Assistant Secretary of the Army for Civil Works (Secretary).

MRRIC recommends the USACE, in concert with the USFWS, proceed with a series of seven proposed actions (see below) for moving forward on fulfillment of the ISAP Final Report recommendations. These proposed actions are consistent with the ISAP recommendations; however they include some additional clarifications, based on MRRIC exchanges with the ISAP, which the Committee believes will be beneficial.

The Committee is providing these proposed actions based on: 1) review of the ISAP report;¹ 2) the clarifications from the ISAP in response to questions raised;² and 3) building on MRRIC's understanding of the conceptual process for moving forward as laid out by the agencies to the SAM Work Group in mid-April.³

As you consider the Committee's recommendations, please consider the following quote from the ISAP's Final Report, which provides useful context for MRRIC's role as efforts to move forward with the ISAP's recommendations are undertaken.

"The ISAP views our role as providing interpretations of available science and preparing scientific findings to inform the decision-making process of the MRRIC. Further, we identify

¹ ISAP Final Report on Spring Pulses and Adaptive Management, November 30, 2011

² See clarification communications from the ISAP (December 12, 2011; summary of January 26, 2012 SPA Task Group call with ISAP and follow-on clarification; April 9, 2012)

³ This conceptual framework will be shared with the full MRRIC in preparation for the May meeting and presented prior to MRRIC reaching closure on this recommendation.

gaps in information that, if filled, could enhance the knowledge upon which river management decisions can be made. We expect MRRIC to use the ISAP findings and interpretations to assess what actions are actually feasible, possible, and/or practicable given other constraints, including social constraints and existing Authorized Purposes, on the system.”

The Committee further supports the ISAP’s further definition of the term “social constraints” as intended to refer to non-scientific factors including social, cultural, economic, legal, or other considerations.⁴

Proposed Actions

1. An effects analysis should be developed that incorporates new knowledge that has accrued since the 2003 Amended Biological Opinion. As part of this analysis:
 - The effects of the Missouri and Kansas River Operations on the listed species should be reviewed and analyzed in the context of other stressors on the listed species;
 - The quantitative effects of potential management actions on the listed species should be documented to the extent possible; and
 - These potential management actions should be incorporated into the CEMs.
2. Conceptual ecological models should be developed for each of the three listed species and these models should articulate the effects of stressors and mitigative actions (including but not limited to flow management, habitat restoration actions, and artificial propagation) on species performance.
3. Other managed flow programs and adaptive management plans should be evaluated as guidance in development of the CEMs and AM strategy for the Missouri River Recovery Program.
4. An overarching adaptive management strategy should be developed that anticipates implementation of combined flow management actions and mechanical habitat construction, and this strategy should be used to guide future management actions, monitoring, research, and assessment activities within the context of regulatory and legal constraints.
5. Monitoring programs along the Missouri River should be designed so as to determine if hypothesized outcomes are occurring and the extent to which they are attributable to specific management actions.
6. The agencies should identify decision criteria (trigger points) that will lead to continuing a management action or selecting a different management action. A formal⁵ process should be designed and implemented to regularly compare incoming monitoring results with the decision criteria.

⁴ See April 9, 2012 ISAP Response to 3/22/12 SPA TG Clarification Questions

⁵ See April 9, 2012 ISAP Response to 3/22/12 SPA TG Clarification Questions

7. Aspects of how the entire hydrograph influences the three listed species should be evaluated when assessing the range of potential management actions.

We look forward to working with you on efforts to implement the proposed actions as defined in the SAM Work Group charge. The Committee thanks you for the opportunity to provide input on the efforts to implement the recommendations included in the ISAP's Final Report and hopes you thoughtfully consider our recommendations.

Respectfully,

A handwritten signature in black ink, appearing to read "Michael Mac". The signature is fluid and cursive, with the first name "Michael" written in a larger, more prominent script than the last name "Mac".

Dr. Michael Mac

Chair

Mr. David Ponganis
Director of Programs
U.S. Army Corps of Engineers

Subject: Transmittal of MRRIC Human Considerations Objectives and Metrics and accompanying Prologue

The attached file contains the MRRIC recommended set of Human Considerations objectives and metrics agreed upon by the Committee at the August 2014 plenary meeting. This document represents significant effort by MRRIC members and Agency staff which began in January 2013 and evolved into this consensus recommendation.

Although divided into two sections, the Prologue and the Objectives and Metrics, it is critical to point out that the recommendation package is the combination of the two. The Prologue sets out specific caveats by which the human considerations objectives and metrics can be used and interpreted.

Among the limitations set forward in the Prologue is that these objectives are only valid for alternatives that are within the sideboards articulated in the January 10, 2014 memorandum (attached to the Prologue). It is also important to understand that while each member does not endorse every objective and performance metric included, as a group MRRIC agrees that this set of objectives and metrics will assist efforts to evaluate Management Plan alternatives and future consideration of these alternatives.

Please feel free to contact me with any questions.

A handwritten signature in black ink that reads "Michael J Mac". The signature is fluid and cursive, with the first letters of each word being capitalized and prominent.

Michael J Mac, Ph.D.
Chair
Missouri River Recovery Implementation Committee

DEPARTMENT OF THE ARMY
CORPS OF ENGINEERS, NORTHWESTERN DIVISION
PO BOX 2870
PORTLAND OR 97208-2870

December 6, 2017

Gail Bingham
Chair, Missouri River Recovery Implementation Committee
c/o U.S. Army Corps of Engineers
601 East 12th Street
Kansas City, Missouri 64106-2896

Dear Ms. Bingham:

Thank you for your email dated November 7, 2017 transmitting the Missouri River Recovery Implementation Committee's (MRRIC) consensus recommendation on the Common Ground Recommendations for USACE listed as follows:

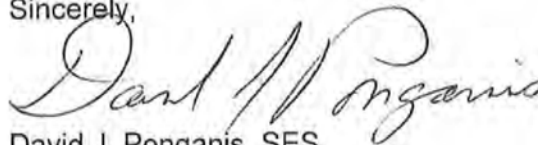

1. When using the word "channel" in the Final Environmental Impact Statement/Adaptive Management Plan, there should be clarification of its definition in the context that it was used.
2. MRRIC affirms and supports USACE's commitment to conduct the supplemental flood risk modeling recommended by the IEPR in Panel Comment 39.
3. USACE should develop criteria for use in the discussion of the Missouri River Recovery Program (MRRP) 5-year Strategic Plan to help inform discussion on how to prioritize the MRRP budget. These criteria should be shared at a MRRIC meeting.

The U.S. Army Corps of Engineers (Corps) appreciates the time and effort put forth by the Committee's members to develop these recommendations. This letter constitutes the Corps' response to MRRIC's recommendation, in accordance with the Committee's Charter.

1. We concur with the recommendation to define the word "channel" in more detail depending on the context in which it is used in the FEIS.
2. We appreciate affirmation from MRRIC, consistent with the Independent Social Economic technical Review Panel (ISETR) comment 39 on the Draft EIS, that if a spawning cue is determined to be necessary, conducting supplemental flood risk modeling would be conducted.
3. We concur with the recommendation and will develop and share criteria that assists us in prioritizing the MRRP budgets in light of the 5-year Strategic Plan.

We look forward to continuing to work with MRRIC and receive recommendations that allow us to collectively be strategic in the implementation of the Missouri River Recovery Program. If you have additional questions, please contact Mark Harberg at 402-995-2554 or Lisa Rabbe at 816-389-3837.

Sincerely,

A handwritten signature in cursive script, reading "David J. Ponganis".

Gail Bingham
Chair, Missouri River Recovery Implementation Committee
c/o U.S. Army Corps of Engineers
601 East 12th Street
Kansas City, Missouri 64106-2896

Dear Ms. Bingham:

Thank you for your email dated November 7, 2017 transmitting the Missouri River Recovery Implementation Committee's (MRRIC) consensus recommendation on the Missouri River Recovery Program (MRRP) draft Science and Adaptive Management Plan (AM Plan). The U.S. Army Corps of Engineers (Corps) appreciates the time and effort put forth by the Committee's members to thoughtfully consider MRRIC's interaction with the MRRP when implementing under Adaptive Management (AM). This letter constitutes a joint response from the Corps' and USFWS to MRRIC's recommendation in accordance with the Committee's Charter.

The Corps and Service concur and will conduct ongoing discussions with MRRIC explaining rationales for funding research, monitoring and evaluation to appropriately support the Integrated Science Program and will further describe or elaborate this interaction in the AM Plan.

The Corps and Service concur and will endeavor to provide additional clarification in the Adaptive Management Plan about the information and criteria to be used in deciding either to:

1. Continue with, but modify, a hypothesis or management strategy, or
2. Put aside a hypothesis and focus on a different hypothesis or management strategy.

We look forward to continuing to mutually work together as we develop the 5-year Strategic Plan. If you have additional questions, please contact Mark Harberg at 402-995-2554 or Lisa Rabbe at 816-389-3837.

Sincerely,

David J. Ponganis, SES

APPENDIX H: TRIBAL ENGAGEMENT

Intentionally Left Blank

APPENDIX H

Missouri River Recovery Management Plan-EIS (MRRMP-EIS) Tribal Correspondence

Table of Contents:

- **List of the 29 Missouri River Tribes:** List of the 29 federally recognized Tribes in the Missouri River Basin.
- **Example Tribal Scoping Letter for the MRRMP-EIS:** Scoping letters were sent to the identified 29 Tribes in July, 2013 informing Tribes of the MRRMP-EIS and requesting input. Additionally, the letter offered formal Government-to-Government Consultation at any time it is requested by Tribal leaders.
- **Example MRRMP-EIS Tribal Input Meeting Invite Letters:** Meetings were conducted during the summer of 2015 to share information and gather Tribal input on the in-progress MRRMP-EIS. These meetings were requested by MRRIC Tribal representatives for further explanation of the MRRMP-EIS and to gather additional information.
- **Example Draft EIS release letter:** In October 2016, a letter from Major General Spellmon was sent to the 29 identified Tribes, informing leaders of the release of the Draft EIS in December 2016 and plans for Consultation upon its release.
- **Example Final EIS and Biological Opinion Consultation Letter:** In December of 2017, a letter from Major General Spellmon was sent to the 29 identified Tribes, informing leaders of the release of the Draft Biological Opinion and efforts to finalize the MRRMP-EIS. The letter offered consultation on the Biological Opinion and on the EIS prior to their finalization.
- **National Historic Preservation Act Section 106 Programmatic Agreement Letters:** In December of 2016, the USACE sent a letter to the 29 identified Tribes announcing the availability of the Draft EIS and an invitation to participate in Section 106 consultation for the MRRMP-EIS. In October of 2017 a Draft Lower Missouri River NHPA Section 106 Programmatic Agreement was circulated to Tribes in the lower Missouri River Basin for review and comment.
- **Final Tribal Consultation Plan:** This plan outlines the consultation process for the MRRMP-EIS including process, guidelines, and communications and includes a summary table of Tribal engagement that occurred during the MRRMP-EIS process.

Missouri River Basin Tribes

Apsaalooke (Crow) Nation	Omaha Tribe of Nebraska
Assiniboine and Sioux Tribe of Fort Peck	Osage Nation
Blackfeet Tribe	Ponca Tribe of Nebraska
Cheyenne River Sioux Tribe	Prairie Band Potawatomi Nation
Chippewa Cree Tribe of Rocky Boy's	Rosebud Sioux Tribe
Crow Creek Sioux Tribe	Sac and Fox Nation of Missouri in Kansas
Eastern Shoshone Tribe	Santee Sioux Tribe of Nebraska
Flandreau Santee Sioux Tribe	Sisseton-Wahpeton Oyate
Gros Ventre and Assiniboine Tribes of Fort Belknap	Spirit Lake Sioux Tribe
Iowa Tribe of Kansas and Nebraska	Standing Rock Sioux Tribe
Kickapoo Tribe of Kansas	Three Affiliated Tribes
Lower Brule Sioux Tribe	Turtle Mountain Band of Chippewa Indians
Northern Arapaho Tribe	Winnebago Tribe of Nebraska
Northern Cheyenne Tribe	Yankton Sioux Tribe
Oglala Sioux Tribe

Planning, Environmental Resources,
Fish Policy and Support Division

The U.S. Army Corps of Engineers (Corps) is committed to working closely with sovereign tribal nations, along with other governmental and non-governmental stakeholders in the Missouri River Basin (Basin), to develop a Missouri River Recovery Management Plan and Environmental Impact Statement (Management Plan/EIS). The Management Plan/EIS will identify a set of actions for the Corps to implement to ensure that our operation of the Missouri River mainstem reservoirs and the Bank Stabilization and Navigation Project does not jeopardize the continued existence of three Federally-listed species: the pallid sturgeon, the interior least tern, and the piping plover.

The Management Plan/EIS is being developed collaboratively with the Missouri River Recovery Implementation Committee (MRRIC). I strongly encourage you and your tribe to participate in MRRIC to improve your understanding of the effort and to take advantage of every opportunity to ensure your voice is heard as the plan comes together. All Basin tribes are members of MRRIC and my staff will be happy to provide more information to you about MRRIC.

The Corps understands and respects the unique relationship the tribes have with the Missouri River and wants to ensure that you have the opportunity outside of MRRIC to communicate directly with the Corps and provide input to the Management Plan. The Corps will hold a special, day-long meeting for the Basin tribes on May 6, 2015, 0800-1600, at the Oglala Sioux Rural Water Supply System (OSRWSS) Mni Wiconi - Water Treatment Plant at 28542 Trails End Road, Ft. Pierre, SD (Conference Room). All tribes within or connected to the Basin are invited to attend and participate. A draft agenda for the meeting is enclosed to this letter and we welcome your feedback on that, as well.

The Corps recognizes its responsibilities and reiterates its commitment to conduct formal government-to-government consultation with the tribes in the Basin as outlined in Executive Order 13084. Participation in MRRIC and at the tribes-only meeting is not

meant to replace this government-to-government consultation. Government-to-government consultation can be requested at any time.

Again, we want to ensure that Basin tribes are knowledgeable about the Management Plan and are aware of the various ways they can participate. Ms. Cathi Warren, Native American Consultation Specialist, will be contacting you in the next two weeks to follow up on this letter. You may also contact Ms. Warren directly at 402-995-2684 or by email at catherine.j.warren@usace.army.mil for questions or clarifications. Your input and participation are important and we look forward to working with you.

Sincerely,

A handwritten signature in black ink, appearing to read 'J. Kem', is positioned above the printed name.

John S. Kem
Brigadier General, US Army
Division Commander

Enclosure

Missouri River Management Plan Tribal Meeting

May 6th Pierre, SD 8:00-4:00

8:00-8:30	Prayer and Introductions - Cathi Warren
8:30-9:00	Overview of Management Plan and Proact. Probably want to briefly cover MRRIC here and the connection with the Management Plan and why the Management Plan is "going" through MRRIC - Mark Harberg
9:00-10:00	Overview of Effects Analysis and results, i.e. management hypotheses and actions - Joe Bonneau
10:00-10:45	Status of "Alternative plans" - Mark Harberg
10:45-12:00	Overview of Hydrologic and Hydraulic Modeling, explain what this is- Use visualization tool to show "Existing Operation" and example of a Round 1 alternative - Jeff Tripe
12:00-1:00	LUNCH
1:00-2:30	Human Considerations and Human Consideration Proxy Measures, what are they and how they work - Use visualization tool to show HC proxy results for "Existing Operation" and example Round 1 alternative - Thomas Topi
2:30-3:00	Adaptive Management, how does/will this work - Joe Bonneau
3:00-3:30	What is happening next? At what point will we engage the tribes outside of MRRIC again - Mark Harberg
3:30-4:00	Wrap up and additional questions -- Cathi Warren

Dear «Salutation» «Last_Name»:

The U.S. Army Corps of Engineers (Corps) is committed to working closely with sovereign tribal nations, along with other governmental and non-governmental stakeholders in the Missouri River Basin (Basin), to develop a Missouri River Recovery Management Plan (Management Plan). The Management Plan will identify a set of actions for the Corps to implement to ensure that our operation of the Missouri River mainstem reservoirs and the Bank Stabilization and Navigation Project does not jeopardize the continued existence of three Federally-listed species: the pallid sturgeon, the interior least tern, and the piping plover.

The Corps understands and respects the unique relationship the tribes have with the Missouri River and is holding a second meeting the first of which was held on May 6th, to provide input to the Management Plan. The Corps will hold a day-long meeting for the Basin tribes on July 14th, 2015, 8:00 a.m. to 4:00 p.m., at the Royal River Casino and Hotel, 607 Veterans St, Flandreau, SD. All tribes within or connected to the Basin are invited to attend and participate. A draft agenda for the meeting is attached to this letter and we welcome your feedback on it, as well. A block of rooms are being held under the name Great Plains Tribal Water Alliance, please call (877) 912-5825 for reservations.

The Management Plan is being developed collaboratively with the Missouri River Recovery Implementation Committee (MRRIC). I strongly encourage you and your tribe to participate in MRRIC to improve your understanding of the effort and to take advantage of every opportunity to ensure your voice is heard as the plan comes together. All Basin tribes are members of MRRIC and my staff will be happy to provide you with more information about MRRIC.

The Corps recognizes its responsibilities and reiterates its commitment to conduct formal government-to-government consultation with the tribes in the Basin as outlined in Executive Order 13084. Participation in MRRIC and the tribes-only meeting is not meant to replace this government-to-government consultation. Government-to-government consultation can be requested at any time.

Again, we want to ensure that Basin tribes are knowledgeable about the Management Plan and are aware of the various ways they can participate. Ms. Cathi Warren, Native American Consultation Specialist, will be contacting you in the next two weeks to follow up on this letter. You may also contact Ms. Warren directly at (402) 995-2684 or by email at catherine.j.warren@usace.army.mil for questions or clarifications. Your input and participation are important and we look forward to working with you.

PORTLAND OR 97208-2870

OCT 20 2016

Chairman Dave Archambault, II
Standing Rock Sioux Tribe
P.O. Box D
Fort Yates, ND 58538

Dear Chairman Archambault:

The Missouri River Recovery Management Plan, Draft Environmental Impact Statement (MRRMP-DEIS) is an effort that will evaluate the effectiveness of current Missouri River Recovery Program management activities and recommend any needed modifications to more effectively create habitat and avoid jeopardy to the following threatened and endangered species: the least tern, piping plover and pallid sturgeon.

This effort is led by the U.S. Army Corps of Engineers' (USACE) Kansas City (NWK) and Omaha (NWO) Districts in partnership with the U.S. Fish and Wildlife Service (USFWS). The geographic scope of the federal action includes the Missouri River within its meander belt from the headwaters of Fort Peck Lake in Montana to its confluence with the Mississippi River near St. Louis, Missouri.

At this time, we would like to offer you the opportunity to meet and discuss the DEIS development and review process and share your thoughts and concerns with regard to the project. The MRRMP-DEIS will be released in December 2016 and a copy of the document will be sent for your review. At that time we will invite you to meet or consult on the DEIS and the preferred alternative.

We appreciate your attention regarding this matter and we look forward to working with you on this important effort. In closing, Ms. Cathi Warren, Missouri River Programs Tribal Consultation Specialist, will be contacting you to identify appropriate tribal points of contact, and schedule meetings as requested. In the interim, should you have any questions, please feel free to contact Mr. Mark Harberg, Program Manager, at (402-995-2554), or Ms. Warren at (402-995-2684).

Sincerely,

Scott A. Spellmon

PO BOX 2870
PORTLAND OR 97208-2870

December 18, 2017

Chairman Floyd Azure
Assiniboine and Sioux Tribes of Fort Peck
P.O. Box 1027
510 Medicine Bear Road
Poplar, Montana 59255

Dear Chairman Azure:

The Missouri River Recovery Management Plan, Environmental Impact Statement (MRRMP-EIS) is an effort that evaluates the effectiveness of current Missouri River Recovery Program (MRRP) management activities and alternatives to more effectively create habitat and avoid jeopardy to the following threatened and endangered species: the least tern, piping plover and pallid sturgeon.

This effort is led by the U.S. Army Corps of Engineers' (USACE) Kansas City and Omaha Districts in partnership with the U.S. Fish and Wildlife Service (USFWS). The geographic scope of the federal action includes the Missouri River within its meander belt from the headwaters of Fort Peck Lake in Montana to its confluence with the Mississippi River near St. Louis, Missouri.

On December 15, 2016 USACE and USFWS made the Draft MRRMP-EIS (DEIS) available for review and offered consultation to Tribes in the basin and with historic ties to the Missouri River. USACE is in the process of revising the DEIS to address comments received and a Final EIS is expected to be released in the fall of 2018. USACE re-initiated formal Endangered Species Act (ESA) consultation with USFWS on October 30, 2017 with submittal of a Biological Assessment (BA). A link to the BA and its Appendices can be found on the MRRP website at <http://morriverecovery.usace.army.mil/mrrp/f?p=136:70:0::NO>. The USFWS will provide a draft Biological Opinion (BO) in early February 2018 and we will provide a link for your review at that time.

At the present time we would like to offer you the opportunity to begin planning and scheduling meetings for continued consultation following release of the draft BO. At these meetings we will be able to share with you any potential changes to the preferred alternative identified in the DEIS. To ensure that we have adequate time to properly consider the results of our consultation meetings as we prepare the Final EIS, we would like to complete consultation by early July 2018.

As we move forward with this engagement, please reference previous letters on this topic, sent October 20, 2016 and December 16, 2016 on behalf of myself and Ms.

Noreen Walsh, USFWS Mountain-Prairie Regional Director. We appreciate your attention regarding this matter and we look forward to working with you on this important effort. In closing, Ms. Cathi Warren, Missouri River Programs Tribal Consultation Specialist, will be contacting you to identify appropriate tribal points of contact, and schedule meetings as requested. In the interim, should you have any questions, please feel free to contact Ms. Tiffany Vanosdall, MRRMP-EIS Project Manager, at (402)995-2695, or Ms. Warren at (402)995-2684.

Sincerely,

A handwritten signature in black ink, appearing to read "Scott A. Spellmon". The signature is fluid and cursive, with a long horizontal stroke extending to the right.

REPLY TO
ATTENTION OF

DEPARTMENT OF THE ARMY
CORPS OF ENGINEERS, OMAHA DISTRICT
1616 CAPITOL AVENUE
OMAHA NE 68102-4901

December 16, 2016

District Commander

Mr. Floyd Azure, Chairman
Assiniboine and Sioux Tribes of Fort Peck
P.O. Box 1027
510 Medicine Bear Road
Poplar, Montana 59255

Dear Chairman Azure:

The Kansas City and Omaha Districts of the U.S. Army Corps of Engineers (USACE), in cooperation with the U.S. Fish and Wildlife Service (USFWS) have developed a draft Missouri River Recovery Management Plan and Environmental Impact Statement (MRRMP-EIS). This document is a programmatic assessment of (1) major federal actions necessary to avoid a finding of jeopardy to the pallid sturgeon, interior least tern, and the Northern Great Plains piping plover caused by operation of the Missouri River Mainstem and Kansas River Reservoir System and operation and maintenance of the Missouri River Bank Stabilization and Navigation Project (BSNP) in accordance with the Endangered Species Act (ESA) of 1973, as amended; and (2) the Missouri River BSNP fish and wildlife mitigation plan described in the 2003 Record of Decision (ROD) and authorized by the Water Resources Development Acts (WRDA) of 1986, 1999, and 2007. The geographic scope of the federal action includes the Missouri River within its meander belt from the headwaters of Fort Peck Lake in Montana to its confluence with the Mississippi River near St. Louis, Missouri. The draft MRRMP-EIS will be available in December 2016 for public review and comment.

Section 106 of the National Historic Preservation Act (NHPA) requires USACE to consult with interested parties on its undertakings, including the MRRMP-EIS. The scope and programmatic nature of the MRRMP-EIS, make it unreasonable to determine the effects of site-specific projects, or undertakings, at this time. USACE will consult with interested parties prior to implementation of each site specific action in addition to this consultation on the draft MRRMP-EIS.

In compliance with Section 110 of NHPA, USACE plans to use programmatic agreements (PA) to fulfil its NHPA responsibilities for consultation on the MRRMP-EIS. The Omaha District will follow the 2004 Programmatic Agreement on the Operation and Management of the Missouri River Main Stem System for compliance with the NHPA. Non-signatories to this PA can request an alternative process at any time throughout the consultation process. In addition, the Kansas City District is planning to develop a new PA for NHPA compliance for use in the lower basin of the Missouri River from Rulo, Nebraska to the mouth of the Missouri River near St. Louis, Missouri. If your party does

not wish to participate in either PA, consultation will still occur for the MRRMP-EIS and after for site specific projects, as required by Section 106.

I invite interested parties to participate in Section 106 consultation for the MRRMP-EIS. We also ask you to identify a representative to serve as an NHPA point of contact for this effort.

My staff will be contacting you in the near future regarding the MRRMP-EIS. If you have any questions please contact:

- MRRP Tribal Consultation Specialist - Ms. Cathi Warren at (402) 995-2684 or catherine.j.warren@usace.army.mil.
- Omaha District - Ms. Julie Price at 402-995-2706 or julie.a.price@usace.army.mil
- Kansas City District - Mr. Timothy Meade at (816) 389-3138 or timothy.m.meade@usace.army.mil,

We appreciate your consideration regarding the matter and look forward to working with you on this important matter.

Sincerely,

John W. Henderson, P.E.
Colonel, Corps of Engineers
District Commander

Planning Branch

Chairwoman Jacque Secondine Hensley
Kaw Nation
P.O. Box 50
Kaw City, OK 74641

Dear Chairwoman Hensley:

This letter is a follow up to a December 16, 2016, letter informing your tribe of the U.S. Army Corps of Engineers (Corps) development of a draft Missouri River Recovery Management Plan and Environmental Impact Statement (MRRMP-EIS) being undertaken in cooperation with the U.S. Fish and Wildlife Service. That letter also informed you of the Corps' plans to comply with Section 106 of the National Historic Preservation Act (NHPA) through the use of cultural resource programmatic agreements (PA) for the upper and lower Missouri River basin. The Corps' Omaha District will follow the 2004 Programmatic Agreement on the Operation and Management of the Missouri River Main Stem System for compliance with the NHPA. The Kansas City District is now in the process of developing a PA for the MRRMP-EIS for the lower basin of the Missouri River from Rulo, Nebraska to the mouth of the Missouri River near St. Louis, Missouri. Attached for your review and comment is a draft copy of the Kansas City District PA for the lower Missouri River basin. The draft PA includes comments and edits provided by the Osage Nation. You are being provided two copies including a clean copy and a copy showing the Osage Nation's edits.

The Corps is using PAs to comply with Section 106 as the scope and programmatic nature of the MRRMP-EIS make it unreasonable to determine the effects of site-specific projects or undertakings prior to completion of the MRRMP-EIS. At this time we invite the Kaw Nation to participate in development of the PA and to be an invited signatory or concurring party to the PA. If your Tribe does not wish to participate in the PA, consultation will still occur for the MRRMP-EIS and after for site specific projects, as required by Section 106.

As you review the draft PA, I encourage you to contact me with any questions or concerns you may have regarding the document at (816) 389-3138 or by e-mail at timothy.m.meade@usace.army.mil. A copy of this letter is also being provided to Ms. Crystal Douglas of your staff. We appreciate your consideration regarding participation in the PA and look forward to working with you on this important matter.

Sincerely,

Timothy Meade
Senior District Archeologist and
Tribal Liaison

Enclosure

TRIBAL CONSULTATION PROCESS FRAMEWORK FOR THE
Missouri River Recovery Management Plan Environmental Impact Statement

I. Identification of Parties for Consultation

All Federally Recognized Tribes geographically located within the Missouri River Basin or that have historical ties within the basin have been identified as potential consulting parties. For this process, the term “Tribe(s)” refers to Federally Recognized Tribes. These Tribes are acknowledged to have all the immunities and privileges available to all Federally Recognized Tribes, as well as, the responsibilities, powers, limitations and obligations by virtue of their Government-to-Government relationship with the United States. The Department of Interior, Bureau of Indian Affairs (BIA), maintains a list of all Federally Recognized Tribes. Updates to this list are posted in the Federal Register (81 FR 26826).

Tribal points of contact will be asked to identify other potentially interested Tribes, Tribal affiliates and Tribal grassroots organizations that may have an interest in the Missouri River Recovery Management Plan (MRRMP) via letter, phone, and/or in person. If additional interested parties are identified during Consultation with Federally Recognized Tribes, they will be brought into the Consultation Process.

The U.S. Fish and Wildlife Service (Service) Native American Liaison will assist as the interface for logistics, communication, scheduling, tracking actions items relevant to the and attendance decisions for Service Region 6 leadership. The Service will jointly offer Consultation in conjunction with the USACE. This strategy will help to efficiently engage Tribal and agency leaderships’ time and reduce confusion that could be created with multiple agencies engaging separately.

Regional Director, Noreen Walsh will delegate Consultation authority for the MRRP EIS to Michael Thabault, Assistant Regional Director for Ecological Services and Missouri River Coordinator Casey Kruse. The letters offering consultation should be signed jointly by agency Regional Directors. The Service will be responsible for Endangered Species Act Section 7 during the Consultations.

II. Communications

Coordination and communication with the Tribes will occur and continue throughout the Consultation Process. Open and honest communication is the foundation of Government-to-Government Consultation. Consulting parties are encouraged to take advantage of opportunities to exchange information and discuss issues during both informal forums and the formal Consultation Process. Forms of communication to be used during the Consultation Process include face-to-face meetings when possible, letters, email and telephone. It is important to remember that informal meetings/forums are not considered “Government-to-Government Consultation” and should be made clear to all that attend. A list of formal and informal Tribal engagement that occurred leading up to the Final MRRMP-EIS is included in Appendix A.

III. Consultation Process

Any time a Tribal leader and/or their designee requests formal Consultation, the Missouri River Recovery Programs Tribal Consultation Specialist (MRRP Consultation Specialist) will be the lead. The Consultation will take place with the appropriate District, NWK or NWO, based upon the Tribe's location and/or area of interest. The appropriate District Tribal Liaison and Program and Project Managers will support the MRRP Consultation Specialist with planning and executing the Consultation to ensure compliance with the requirements of all applicable statutes, executive orders, or other applicable laws.

The Corps' MRRP Consultation Specialist will ensure that the Service Regional Native American Liaison is aware of all meeting times, locations, agendas, correspondence, and other pertinent information. It is the responsibility of the Service Region Leadership to participate according to their requirements. The Service Native American Liaison will ensure their agency is aware of those requirements and pertinent Consultation meeting information.

The guidelines below are not intended to replace specifically mandated Consultation requirements, such as those identified in the National Historic Preservation Act (NHPA) or the Native American Graves Protection and Repatriation Act (NAGPRA) implementing regulations. Rather, they would provide a framework for implementation of these and any other requirements.

IV. Consultation Guidelines

The steps in the Government-to-Government Consultation Process for the MRRMP-EIS are:

- Initiation of Government-to-Government Consultation is the responsibility of the both the Corps and Service as required by statute. By written correspondence, the appropriate District Commander will offer to engage in Government-to-Government Consultation with all Federally Recognized Tribes, geographically located within the Missouri River Basin or that have historical ties within the basin, on the MRRMP EIS. This letter will be sent as early in the Process as is reasonable. The purpose of this letter will be to define the MRRMP-EIS and to indicate that this letter is the first step in the formal Government-to-Government Consultation Process.
- After the initial letter is mailed the MRRP Consultation Specialist will follow up by telephone. Information from these telephone calls will be documented and follow-up actions requested by the Tribe will be noted, incorporated as appropriate, and reported to appropriate Corps staff for any necessary follow up. If a Tribe elects not to respond to the initial Consultation letter or the subsequent telephone call, the MRRP Consultation Specialist will periodically, throughout the Consultation Process, attempt to initiate Consultation with the Tribes in the manner described above.
- Tribes may accept the Corps' offer of Government-to-Government Consultation by any form of communication. It is incumbent on the MRRP Consultation Specialist to verify that the decision to consult reflects the wishes of the Tribal Leader or their designee. Though written confirmation is not required, it is preferred.

TRIBAL CONSULTATION PROCESS FRAMEWORK FOR THE
Missouri River Recovery Management Plan Environmental Impact Statement

- In cooperation with the Tribal Leader or their designee, arrangements for an initial Consultation meeting will be made as soon as possible after the Tribe accepts the Corps' offer of Consultation. Consultation meetings will take place at mutually agreed upon intervals and locations. Agendas for the Consultation meetings will be mutually developed by the Consulting Parties and should reflect Consultation issues that are of primary importance to all parties. Some Consultation discussions may also focus on Tribal participation during official National Environmental Policy Act (NEPA) efforts.
- In addition to the Consultation meetings described above, to ensure that there is meaningful Government-to-Government Consultation occurring at critical points during the Study process, the Corps will offer face-to-face meetings with both Consulting and non-Consulting Tribal Leaders or their designees and the appropriate District Commander or his designee. These meetings will be offered at a minimum during the following points in the process:
 - Following the release of the Draft EIS (December 2016)
 - Following the identification of a Preferred Alternative/Proposed Action for initiation of Section 7, ESA consultation, if one is not included in the DEIS
 - Prior to a Record of Decision (ROD)

V. Resolution of Issues

The intent of Government-to-Government Consultation is to provide for identification and resolution of issues related to the management actions being evaluated by the Corps' for ESA compliance regarding the Corps' operation of the Missouri River Mainstem Reservoir System, operation and maintenance of the Bank Stabilization and Navigation Project, and operation of the Kansas River Reservoir System with the respective Corps District; however, resolutions of some issues may be beyond the scope and authority of the District Commanders. Unresolved issues identified in formal Government-to-Government Consultation may be elevated to higher levels within the Corps beginning with the Northwestern Division, Headquarters USACE, and then to the Office of the Assistant Secretary of the Army for Civil Works. Consulting parties will develop joint procedures for elevation and ultimate disposition of unresolved issues. This may include annual meetings to maintain relationships and provide relevant information. Tribal resolutions or other Tribal procedures may also serve as tools for unresolved Tribal issues.

The Service will work with Tribes to elevate an ultimate disposition of unresolved issues using Consultation options such as: putting an emphasis on co-management and collaborative management of natural and cultural resources, in which the Service and tribes share decision-making to the extent permitted by law. These actions can include placing an added emphasis on implementation and accountability, engage tribal knowledge in the Service's decision-making, and provide a consistent national framework flexible enough to accommodate regional and local variations in culture and perspectives.

David Ponganis, Director of Programs
U.S. Army Corps of Engineers
1125 NW Couch Street, Suite 500
Portland, Oregon 97209

Dear Mr. Ponganis:

The U.S. Fish and Wildlife Service (USFWS) has received and reviewed the Missouri River Recovery Program Independent Science Advisory Panel's (ISAP) *Final Report on Spring Pulses and Adaptive Management*, dated November 30, 2011. This report, commissioned by the Missouri River Recovery Implementation Committee (MRRIC), evaluated the pulses that have been implemented to date and how they have achieved the biological outcomes the USFWS sought in the 2003 Amendment to the 2000 Biological Opinion (2003 Amended BiOp), dated December 23, 2003. The ISAP confirmed that spring pulses, as currently implemented, are not accomplishing their intended outcomes and provided recommendations towards achieving a new management paradigm for the Missouri River.

Based on the final report, we have determined that aggressive pursuit of completing the recommendations laid out by the ISAP is the best path forward to ensure we are using the available scientific data to achieve the intent of the 2003 Amended BiOp and species recovery. Accordingly, while completion of the ISAP recommendations is being pursued, the USFWS believes it is appropriate to forego a spring pulse, under the currently established criteria, during the 2013 Missouri River operating season and that not providing a spring pulse is not likely to have an adverse effect on the listed species addressed in the 2003 Amended BiOp.

To ensure timely implementation of the ISAP recommendations, it will be imperative that the U.S. Army Corps of Engineers (USACE) continue its collaboration with the USFWS to quickly develop a schedule, process, and check in points, to ensure the agencies are on track to fully evaluate the needs of Missouri River endangered species and the role hydrology may play in their recovery and long-term sustainability. This process needs to evaluate the complete hydrograph, consider a full range of alternatives to meet species requirements, and result in a sustainable and adaptable management strategy for the Missouri River.

We should all turn our efforts to quickly and efficiently implementing the ISAP recommendations. We also hope that our two agencies will continue working together with Missouri River stakeholders to fully implement all these recommendations. It is possible, even likely, that as the ISAP recommendations are implemented, a new management strategy for flows and habitat restoration will develop, leading to more effective species recovery actions on the Missouri River. We envision that a new management strategy coming off the ISAP effort could be implemented by spring 2014, or during 2015 at the latest, thus replacing the current spring pulse operation with a more comprehensive management plan. We look forward to our first two planned USFWS – USACE check-in points (November 2012 and February 2013) on the progress of implementing the ISAP recommendations.

My staff stands ready to assist in any way they can. If you have any questions, please feel free to contact Casey Kruse, Missouri River Coordinator at (605) 760-7471.

Sincerely,

Regional Director

Draft Pallid Sturgeon Objectives (Upper and Lower Basin) for the Missouri River Recovery Program

As part of the effort to develop a comprehensive adaptive management plan for implementation of the U.S. Army Corps of Engineers (USACE) Missouri River Recovery Program (MRRP), the U.S. Fish and Wildlife Service (USFWS) provides the following species objective for the endangered pallid sturgeon.

While this objective is consistent with USFWS established recovery goals for the pallid sturgeon, it is prepared specifically as a fundamental objective to avoid and prevent jeopardy to the species from the USACE action of operating and maintaining the Missouri River System. This fundamental objective and subsequent sub-objectives describe the desired outcomes from the USACE actions as part of the MRRP.

These objectives are prepared with the following tenants. They should:

- Be consistent with Endangered Species Act required Pallid Sturgeon Recovery Plan recovery goals and strategies,
- Reflect the latest knowledge of the species life history needs and their current status relative to the form and function of the contemporary Missouri River System,
- Have a direct relationship with the USACE's effect on the species from their operations of the Missouri River System, and
- Be sensitive to actionable threat remediation.

Fundamental Objective: Avoid jeopardizing the continued existence of the pallid sturgeon from the US Army Corps of Engineers actions on the Missouri River.

Sub-objective 1: Increase pallid sturgeon recruitment to age 1.

Sub-objective 2: Maintain or increase numbers of pallid sturgeon as an interim measure until sufficient and sustained natural recruitment occurs.

Sub-objectives track progress towards achieving the fundamental objective. They can also help determine which factors contribute most to achieving the fundamental objective. Note that the fundamental and sub-objectives are not independent of each other, and should be considered **together** rather than separately when assessing the state of the system and choosing management actions.

The following sub-objectives are those objectives which must be attained to ultimately allow us to achieve the stated “fundamental objective”. The intent of the sub-objectives is to provide direction in the short term, provide objectives meaningful for adaptive management, and focus efforts on the desired short term outcomes while keeping the fundamental objective in mind. Although attaining a self sustaining population is ultimately the desired outcome, we are likely decades away from such an objective being very meaningful. Even if we achieved natural recruitment in the next 10 years, it would be another 20 to 30 years before we could assess progress toward the self-sustaining population objective.

Sub-objective 1: Increase pallid sturgeon recruitment to age 1.

Metric: catch rates of naturally-produced age 2 and 3 pallid sturgeon

This metric is used because pallid sturgeons are susceptible to sampling gears at these ages AND are still young enough to be accurately aged. If older fish can be accurately aged, their catch rates should be used as well. Close coordination will need to occur with scientists on the Mississippi River to determine if Missouri River fish are recruiting in the Mississippi and eventually returning to Missouri River to spawn. This will require cooperative microchemistry work on young fish.

Target: TBD. Short-term measurable recruitment, long-term informed by the effects analysis and population models. Target values for recruitment (i.e. necessary levels and frequency of recruitment over time) will be informed by population models as part of the effects analysis. Defining this target is not critical right now given that we are not currently concerned with levels or frequency of recruitment given we first need to see measurable recruitment.

Sub-objective 2: Maintain or increase numbers of pallid sturgeon as an interim measure until sufficient and sustained natural recruitment occurs.

This sub-objective really focuses on artificial propagation since it is the only means to achieve this intermediate objective. Monitoring and assessment will be directed at refining the artificial propagation approach and maximizing the utility of the artificial propagation program.

Metric: catch rates of all pallid sturgeon by size class. This metric is in accordance with the recovery guidance provided in the Pallid Sturgeon Recovery Plan and Genetics Plans for the Upper Basin and Lower Basin.

Target: TBD. The target values, by reach, will be informed by the effect analysis.

Means Objectives specify the way and degree to which the fundamental and sub-objectives can be achieved. The MRRP Means Objectives will be defined at a later date after the Effect Analysis is completed.

Note: Following are explanations regarding the above objectives:

These refinements to the objectives are consistent with the discussions at the workshops and incorporate many of the points made at the workshops.

- It is suggested that refining the strategic objective wording to focus on jeopardy avoidance (while including the ‘contributing to recovery’) will avoid ambiguity and confusion. The role of the USACE is to address the impacts of the USACE actions on the species (i.e., jeopardy avoidance). This is the manner in which the USACE contributes to the broader recovery efforts.
- The “Sub-objectives” as previously drafted contained redundancy (e.g., Increase self-sustaining population with a metric of length frequency and Improve population size structure with a metric of length frequency) and are basically synonymous with the stated fundamental objective. Some rewording of these objectives was done to help distinguish between sub-objectives and the fundamental objective.
- The sub-objectives should be viewed in terms of timeframes or immediate relevancy. The sub-objectives in sum ultimately allow us to achieve the fundamental objective in the long-term.
- The objectives as previously stated weren’t particularly responsive to management actions or of utility for adaptive management (i.e., it would take many years to decades to link success back to a management action if our objectives and metrics relate to overall population size or desired population size structure). Adaptive management will require the opportunity to observe responses to management actions in a shorter time frame and an ability to link the response to an action or suite of actions.
- It is clear from the Conceptual Ecological Models (CEMs) and current understanding that without attaining some level of natural recruitment to age 1, it will not be possible to meet other objectives. Lack of recruitment is currently limiting pallid population growth. This is where attention must focus. Doing so shows that we have broken down and understand the problem and will provide some meaning to plan formulation exercises. It may be decades before anything else matters to us (or the pallid population).
- **There are several hypotheses regarding the lack of recruitment to age 1 (especially in the lower basin). These are partially identified in the CEMs, will be further evaluated in the Effects Analysis, and can be addressed in the formulation of alternatives and active adaptive management to come. For example, it could be that we have too few adults to successfully spawn, it could be that there is high egg mortality, it could be that drifting embryos suffer high mortality, it could be that habitat and food availability are limiting, etc., so the problem may actually be occurring prior to recruitment of larval sturgeon to age 1. Although there are multiple hypotheses, the bottom line is that we know fish survive well once they reach age 1 and an objective of getting fish to that point (i.e., recruitment to age 1) is the objective we need to achieve regardless of the early life history problem which is most limiting. In addition,**

the performance metric which can actually be measured is catch of fish once they get to age 2, 3, and 4.

- The CEMs make the link between USACE operation of the river and the loss of recruitment and place high importance on that linkage in both the Upper and Lower Basins. It is important to make that connection between the CEMs and our objectives. We need to show how our objectives are linked to addressing the effects of USACE operations on the species.
- It is important for future reviewers and contributors to understand the origin of and our needs for these objectives, for example:
 - o The objectives stem from the effect of USACE actions and operations on the species and the legal mandate to avoid jeopardizing continued existence of the species;
 - o The objectives will be used in an Effects Analysis;
 - o Assessments of progress toward achieving objectives will be the basis for Adaptive Management efforts moving forward; and
 - o For Adaptive Management purposes, objectives must be responsive within a reasonable time frame (i.e., we can't use monitoring results to affect management change if we must wait 30 to 40 year to interpret the results).

Draft Piping Plover Objective for the Missouri River Recovery Program

As part of the effort to develop a comprehensive adaptive management plan for implementation of the U.S. Army Corps of Engineers (USACE) Missouri River Recovery Program (MRRP), the U.S. Fish and Wildlife Service (USFWS) provides the following species objective for the threatened piping plover.

While this objective is consistent with USFWS established recovery goals for the piping plover, it is prepared specifically as a fundamental objective to avoid and prevent jeopardy to the species from the USACE action of operating and maintaining the Missouri River System. This fundamental objective and subsequent sub-objectives describe the desired outcomes from the USACE actions as part of the MRRP.

These objectives are prepared with the following tenants. They should:

- Be consistent with Endangered Species Act required Piping Plover Recovery Plan recovery goals and strategies,
- Reflect the latest knowledge of the plover's life history needs and their current status relative to the form and function of the contemporary Missouri River System,
- Have a direct relationship with the USACE's effect on the species from their operations of the Missouri River System, and
- Be sensitive to actionable threat remediation.

Fundamental Objective: Avoid jeopardizing the continued existence of the piping plover from the US Army Corps of Engineers actions on the Missouri River.

Sub-objective 1: Maintain a total population number of Missouri River birds that keep the population resilient on the Missouri River in the long term.

Sub-objective 2: Maintain a long-term trend in population growth that is at least stable.

Sub-objective 3: Increase and maintain the success of breeding pairs on Missouri River.

Sub-objective 4: Maintain a geographic distribution of plovers in the river and reservoirs in which they currently occur.

Sub-objectives track progress towards achieving the fundamental objective. They can also help determine which factors are contributing to an inability to reach the fundamental objective. Note that the fundamental and sub-objectives are not independent of each other, and should be considered **together** rather than separately when assessing the state of the system and choosing management actions.

The following sub-objectives are those objectives which must be attained to ultimately allow us to achieve the stated “fundamental objective”. The intent of the sub-objectives is to provide direction in the short term, provide objectives meaningful for adaptive management, and focus efforts on the desired short term outcomes while keeping the fundamental objective in mind.

Sub-objective 1: Maintain a total population number of Missouri River birds that keep the population resilient on the Missouri River in the long term.

Metric: Total Missouri River population size, frequency of years that population size is above target.

Target: TBD and informed by Effects Analysis.

Resilient can be defined by a population size that is large enough to withstand and recover from system shocks. Resiliency of the Missouri River population is interdependent of the population range-wide considering that the birds are known to sometimes use habitat elsewhere. Targets can be estimated with population viability analysis (PVA) models once an acceptable level of risk is specified, e.g. a 5% risk of extirpation over the next 50 years.

Population targets may also be specified as frequencies (e.g. populations should be above target 2 years out of 3; a 3-year running average of the population should be above target) to reflect the natural variability of plover habitat and population sizes. While this does not support the resiliency of the population, it can be used as part of adaptive management to determine when actions should be triggered in response to population sizes falling below the target.

Sub-objective 2: Maintain a long-term trend in population growth that is at least stable.

Metric: population growth rate (λ).

Target: $\lambda \geq 1$.

Population growth rate is nothing more than the change in population size over time. In other words, it is the trend in the fundamental objective. Growth rates (λ) larger than one lead to an increase in population size, while growth rates less than one lead to a decrease in population size. This metric is used to determine whether population sizes below target are on track to reach the target, and whether population sizes above target are likely to remain there.

This metric is also important because there are biological constraints on population growth, and thus time lags before small populations can respond to improved conditions and reach the target. This metric allows for determination of whether management is successful in the short term.

Sub-objective 3: Increase and maintain the success of breeding pairs on Missouri River.

Metric: number of fledglings/breeding pair, or survival to fledge.

Target: TBD, informed by Effects Analysis.

An assessment of productivity is critical to determining the extent to which plover population trends are dependent upon conditions on the Missouri River rather than to conditions at wintering habitat outside of the basin, and therefore whether they can be affected by the MRRP. A decrease in population growth rate and size may be due to reduced productivity or decreased overwinter survival. Conversely, decreases in productivity may be masked in the short term if overwinter survival improves. Rates of fledgling production alone do not determine the health of the population (a very small population may have high fledge ratios), but instead must be considered together with population size and growth rate. Reduced productivity can be tolerated and, for plovers, expected when population sizes are large; however, small populations with low productivity will not recover in the absence of sufficient immigration from other populations. One downside of using fledglings/breeding pair is that the calculation amplifies the error inherent in survey data. Another issue with fledge ratio is the ability to accurately count fledglings without marking them, fledglings fly and can therefore easily be counted multiple times if they are not uniquely marked. Survival to fledge will require bird banding but will provide more accurate tracking of fledglings.

Sub-objective 4: Maintain a geographic distribution of plovers in the river and reservoirs in which they currently occur.

Metric: population size by reach, or proportion of population within each reach.

Target: TBD, informed by Effects Analysis

This sub-objective could be considered separately rather than as part of the fundamental objective, depending on emphasis desired. The geographic distribution of birds throughout the river supports population resilience by reducing the likelihood of local disturbances having catastrophic effects on the population. It will also likely support a larger population of plovers, as there is potential for more habitat when larger parts of the river are considered, and increased habitat supports increases in population sizes.

Means Objectives specify the way and degree to which the fundamental and sub-objectives can be achieved. The MRRP Means Objectives will be defined at a later date after the Effect Analysis is completed.

Note: Following are explanations regarding the above objectives:

These objectives are consistent with the discussions at the workshops and incorporate many of the points made at the workshops.

- It is suggested that refining the strategic objective wording to focus on jeopardy avoidance (while including the ‘contributing to recovery’) will avoid ambiguity and confusion. The role of the USACE is to address the impacts of the USACE’s actions on the species (i.e., jeopardy avoidance). This is the manner in which the USACE contributes to the broader recovery efforts, but that point is regularly confused or lost as this debate has consumed many hours over the past two years. The wording should be as concise and unambiguous as possible.
- The “Sub-objectives” as previously drafted contained redundancy and were basically synonymous with the stated fundamental objective. Some rewording of these objectives was done to help distinguish between sub-objectives and the fundamental objective.
- The sub-objectives should be viewed in terms of timeframes or immediate relevancy. The sub-objectives in sum ultimately allow us to achieve the fundamental objective in the long-term.
- The objectives as previously stated weren’t particularly responsive to management actions or of utility for adaptive management (i.e., it would take many years to decades to link success back to a management action if our objectives and metrics relate to overall population size or desired population size structure). Adaptive management will require the opportunity to observe responses to management actions in a shorter time frame and an ability to link the response to an action.
- The Conceptual Ecological Models (CEM) makes the link between USACE operations of the river and meeting the Fundamental Piping Plover Objectives. We need to show how our objectives are linked to addressing the effects of USACE operations on the species.
- It is important for future reviewers and contributors to understand the origin of and our needs for these objectives, for example:
 - o The objectives stem from the effect of USACE actions and operations on the species and the legal mandate to avoid jeopardizing continued existence of the species;
 - o The objectives will be used in an Effects Analysis;
 - o Assessments of progress toward achieving objectives will be the basis for Adaptive Management efforts moving forward; and
 - o For Adaptive Management purposes, objectives must be responsive within a reasonable time frame (i.e., we can’t use monitoring results to affect management change if we must wait 30 to 40 year to interpret the results).

Draft Least Tern Objective for the Missouri River Recovery Program

As part of the effort to develop a comprehensive adaptive management plan for implementation of the U.S. Army Corps of Engineers (USACE) Missouri River Recovery Program (MRRP), the U.S. Fish and Wildlife Service (USFWS) provides the following species objective for the endangered least tern.

While this objective is consistent with USFWS established recovery goals for the least tern, it is prepared specifically as a fundamental objective to avoid and prevent jeopardy to the species from the USACE action of operating and maintaining the Missouri River System. This fundamental objective and subsequent sub-objectives describe the desired outcomes from the USACE actions as part of the MRRP.

These objectives are prepared with the following tenants. They should:

- Be consistent with Endangered Species Act required Least Tern Recovery Plan recovery goals and strategies,
- Reflect the latest knowledge of the species life history needs and their current status relative to the form and function of the contemporary Missouri River System,
- Have a direct relationship with the USACE's effect on the tern from their operations of the Missouri River System, and
- Be sensitive to actionable threat remediation.

Fundamental Objective: Avoid jeopardizing the continued existence of the least tern from the US Army Corps of Engineers actions on the Missouri River.

Sub-objective 1: Maintain a total population number of Missouri River birds that keep the population resilient on the Missouri River in the long term.

Sub-objective 2: Maintain a long-term trend in population growth that is at least stable.

Sub-objective 3: Increase and maintain the success of breeding pairs on Missouri River.

Sub-objective 4: Maintain a geographic distribution of terns in the river and reservoirs in which they currently occur.

Sub-objectives track progress towards achieving the fundamental objective. They can also help determine which factors are contributing to an inability to reach the fundamental objective. Note that the fundamental and sub-objectives are not independent of each other, and should be considered **together** rather than separately when assessing the state of the system and choosing management actions.

The following sub-objectives are those objectives which must be attained to ultimately allow us to achieve the stated “fundamental objective”. The intent of the sub-objectives is to provide direction in the short term, provide objectives meaningful for adaptive management, and focus efforts on the desired short term outcomes while keeping the fundamental objective in mind.

Sub-objective 1: Maintain a total population number of Missouri River birds that keep the population resilient on the Missouri River in the long term.

Metric: Total Missouri River population size, frequency of years that population size is above target.

Target: TBD and informed by Effects Analysis.

Resilient can be defined by a population size that is large enough to withstand and recover from system shocks. Resiliency of the Missouri River population is interdependent of the population range-wide considering that the birds are known to sometimes use habitat elsewhere. Targets can be estimated with population viability analysis (PVA) models once an acceptable level of risk is specified, e.g. a 5% risk of extirpation over the next 50 years.

Population targets may also be specified as frequencies (e.g. populations should be above target 2 years out of 3; a 3-year running average of the population should be above target) to reflect the natural variability of tern habitat and population sizes. While this does not support the resiliency of the population, it can be used as part of adaptive management to determine when actions should be triggered in response to population sizes falling below the target.

Sub-objective 2: Maintain a long-term trend in population growth that is at least stable.

Metric: population growth rate (λ).

Target: $\lambda \geq 1$.

Population growth rate is nothing more than the change in population size over time. In other words, it is the trend in the fundamental objective. Growth rates (λ) larger than one lead to an increase in population size, while growth rates less than one lead to a decrease in population size. This metric is used to determine whether population sizes below target are on track to reach the target, and whether population sizes above target are likely to remain there.

This metric is also important because there are biological constraints on population growth, and thus time lags before small populations can respond to improved conditions and reach the target. This metric allows for determination of whether management is successful in the short term.

Sub-objective 3: Increase and maintain the success of breeding pairs on Missouri River.

Metric: number of fledglings/breeding pair, or survival to fledge.

Target: TBD, informed by Effects Analysis.

An assessment of productivity is critical to determining the extent to which tern population trends are dependent upon conditions on the Missouri River rather than to conditions at wintering habitat outside of the basin, and therefore whether they can be affected by the MRRP. A decrease in population growth rate and size may be due to reduced productivity or decreased overwinter survival. Conversely, decreases in productivity may be masked in the short term if overwinter survival improves. Rates of fledgling production alone do not determine the health of the population (a very small population may have high fledge ratios), but instead must be considered together with population size and growth rate. Reduced productivity can be tolerated and, for terns, expected when population sizes are large; however, small populations with low productivity will not recover in the absence of sufficient immigration from other populations. One downside of using fledglings/breeding pair is that the calculation amplifies the error inherent in survey data. Another issue with fledge ratio is the ability to accurately count fledglings without marking them, fledglings fly and can therefore easily be counted multiple times if they are not uniquely marked. Survival to fledge will require bird banding but will provide more accurate tracking of fledglings.

Sub-objective 4: Maintain a geographic distribution of terns in the river and reservoirs in which they currently occur.

Metric: population size by reach, or proportion of population within each reach.

Target: TBD, informed by Effects Analysis

This sub-objective could be considered separately rather than as part of the fundamental objective, depending on emphasis desired. The geographic distribution of birds throughout the river supports population resilience by reducing the likelihood of local disturbances having catastrophic effects on the population. It will also likely support a larger population of terns, as there is potential for more habitat when larger parts of the river are considered, and increased habitat supports increases in population sizes.

Means Objectives specify the way and degree to which the fundamental and sub-objectives can be achieved. The MRRP Means Objectives will be defined at a later date after the Effect Analysis is completed.

Note: Following are explanations regarding the above objectives:

These objectives are consistent with the discussions at the workshops and incorporate many of the points made at the workshops.

- It is suggested that refining the strategic objective wording to focus on jeopardy avoidance (while including the ‘contributing to recovery’) will avoid ambiguity and confusion. The role of the USACE is to address the impacts of the USACE actions on the species (i.e., jeopardy avoidance). This is the manner in which the USACE contributes to the broader recovery efforts, but that point is regularly confused or lost as this debate has consumed many hours over the past two years. The wording should be as concise and unambiguous as possible.
- The “Sub-objectives” as previously drafted contained redundancy and were basically synonymous with the stated fundamental objective. Some rewording of these objectives was done to help distinguish between sub-objectives and the fundamental objective.
- The sub-objectives should be viewed in terms of timeframes or immediate relevancy. The sub-objectives in sum ultimately allow us to achieve the fundamental objective in the long-term.
- The objectives as previously stated weren’t particularly responsive to management actions or of utility for adaptive management (i.e., it would take many years to decades to link success back to a management action if our objectives and metrics relate to overall population size or desired population size structure). Adaptive management will require the opportunity to observe responses to management actions in a shorter time frame and an ability to link the response to an action.
- The CEMs makes the link between USACE’s operation of the river and meeting the Fundamental Least tern Objectives. We need to show how our objectives are linked to addressing the effects of USACE operations on the species.
- It is important for future reviewers and contributors to understand the origin of and our needs for these objectives, for example:
 - o The objectives stem from the effect of USACE actions and operations on the species and the legal mandate to avoid jeopardizing continued existence of the species;
 - o The objectives will be used in an Effects Analysis;
 - o Assessments of progress toward achieving objectives will be the basis for Adaptive Management efforts moving forward; and
 - o For Adaptive Management purposes, objectives must be responsive within a reasonable time frame (i.e., we can’t use monitoring results to affect management change if we must wait 30 to 40 year to interpret the results).

Noreen Walsh
U.S. Fish and Wildlife Services
134 Union Blvd
Lakewood, CO 80228

Dear Noreen:

As we have discussed, this letter confirms our mutual understanding that the U.S. Army Corps of Engineers (Corps) and the U.S. Fish and Wildlife Service (Service) are engaged in consultation on the 2003 Amended Biological Opinion on the Operation and Maintenance of the Mainstem Missouri River Reservoir System, the Missouri River Bank Stabilization and Navigation Project, and the Kansas Reservoir System (2003 Amended BiOp). The Missouri River Recovery Management Plan and Environmental Impact Statement (MRRMP/EIS), which is currently being developed jointly by our agencies in collaboration with the Missouri River Recovery Implementation Committee (MRRIC), serves as the on-going medium for this consultation. Following release of the draft MRRMP/EIS for public review and comment in 2016, this document will provide the foundation for a revised Biological Assessment (BA) and proposed action for our operation of the Missouri River System. Subject to the conclusions of the revised BA, we anticipate the Service may amend the current BiOp or issue a new BiOp pursuant to regulations governing section 7 of the Endangered Species Act (ESA). Based on this process and public input, the Corps will then be poised to make any appropriate revisions to the draft MRRMP/EIS, issue a final decision, and begin implementation.

The Missouri River Recovery Program's Independent Science Advisory Panel (ISAP), tasked by MRRIC, released a report (Final Report on Spring Pulses and Adaptive Management) on November 30, 2011 that analyzed the efficacy of the managed spring pulse releases from Gavins Point Dam as implemented by the Corps in response to the 2003 Amended BiOp. The ISAP's report identified the need to review the current management actions being taken to benefit the listed species in light of the current state of the science, concluding that there was "substantial new knowledge regarding pallid sturgeon, least tern, and piping plover, their habitats, and management opportunities on the lower Missouri River" since the 2003 Amended BiOp was published (pg 57). The ISAP recommended a "new management agenda using hydrological manipulations and habitat construction activities, implemented in an adaptive management framework" to replace the current action plan (pg 4). To achieve that goal, the panel provided a set of specific guidance and suggestions for the agencies to pursue (pg 4-5). The report also provided recommendations for developing an overarching Adaptive Management (AM) program to systematically address uncertainties involved with implementation of the management actions. As you know, development of an AM plan is also a component of the 2003 Amended BiOp.

On February 21, 2012, the MRRIC supported that guidance and provided our agencies with a formal consensus recommendation, in accordance with their Charter, proposing seven specific actions for the agencies to implement to fulfill the ISAP recommendations. On May 8, 2012, the Corps and Service provided a joint response to the MRRIC's recommendation, endorsing the ISAP's report and expressing our agencies' joint commitment to working closely with the MRRIC to implement the recommended actions.

To implement the ISAP report's recommendations, and in coordination with and building on the corresponding set of recommendations from the MRRIC, our two agencies have been applying a structured scientific process, employing teams of nationally recognized experts, to:

- Complete an Effects Analysis (EA) that includes review and compilation of the best available scientific information,
- Develop Conceptual Ecological Models (CEMs) for the three listed species to articulate the stressors and mitigative actions on species performance ,
- Identify the factors that might be limiting species' success,
- Evaluate a suite of management actions with the potential to remove those limiting factors, including any impacts that may accrue to human considerations,
- Design an overarching AM plan with clear decision criteria and robust and integrated research, monitoring and assessment activities,
- Assess and make appropriate changes to management actions through a management plan for continued compliance with ESA requirements, and
- Demonstrate commitment to implementing that management plan by completing all necessary components to its development, including National Environmental Policy Act (NEPA), Corps' Independent External Peer Review (IEPR), and Fish and Wildlife Coordination Act (FWCA).

Over the past three years, our agencies have invested significant time and resources toward implementing the recommendations and have made tremendous progress.

- The Notice of Intent for the MRRMP/EIS was published in January 2013 following extensive collaboration between our agencies on the study's Purpose and Need.
- The Request for Proposals for the Effects Analyses work was developed jointly by our agencies, reviewed by the ISAP and the MRRIC, and issued in March 2013. Nationally respected experts from the U.S. Geological Survey (pallid sturgeon), Pacific Northwest National Laboratories (least tern and piping plover), and the Corps' Engineer Research

and Development Center (river geomorphology) were selected to lead the EA teams and began work immediately.

- At the suggestion of the Service, a group of key team members, including the Corps, Service, and the Chair of the MRRIC, attended a Structured Decision Making Workshop at the National Conservation Training Center in June 2013 to strengthen our ability to conduct such a complex undertaking as the MRRMP/EIS with such a large and diverse group as the MRRIC.
- Evolving through a series of interim products that were guided by ISAP reviews and feedback, the CEMs for the three species were completed in February 2014.
- At the MRRIC's request, and with our agencies' concurrence, an independent socio-economic panel of experts was selected in April 2014 to provide review and feedback on the economic evaluation of potential MRRMP/EIS alternatives. The three-member Independent Social Economic Technical Review (ISETR) panel supplements the scientific expertise of the ISAP.
- Draft EAs for the species were completed in October 2014; the documents are currently undergoing pre-publication quality reviews.

Key elements that have been developed as part of the EA process include predictive species models, comprehensive hypotheses sets, evidence-based assessments of those hypotheses, and identification of potential management actions. It is safe to say that the breathtaking amount of state-of-the-science information that has been produced as part of this effort is unprecedented.

We appreciate the Service's continued efforts to utilize the EA results to identify objectives and metrics for the species. As you are aware, the species objectives and metrics are critical to development of appropriate management actions. The clear connection of species objectives and metrics to the rigorous scientific processes being followed by the EA teams (and reviewed by the ISAP and the MRRIC) will ensure success in reaching the goals described above.

Our agencies have been working with stakeholders to evaluate potential management action alternatives that achieve species objectives. This includes analyzing the potential impacts of those management actions on a suite of socioeconomic and other human considerations. We are also working with the EA team leads to draft the AM strategies that will systematically address uncertainties involved with implementation of management actions. And all of this has been accomplished with and improved by continuous review and feedback from the ISAP, ISETR, and the MRRIC.

While there is no doubt that our two agencies, working with the MRRIC, EA teams, and review panels, have accomplished much, there is still work to be done. As our agencies continue to refine management actions, assemble and evaluate alternative plans and potential

impacts, develop AM strategies, and select a new management plan, we are committed to maintaining continuous engagement with the Service.

As we jointly work to complete the MRRMP/EIS, the Corps continues to implement the Reasonable and Prudent Alternative (RPA) provisions in the 2003 Amended BiOp, working closely with the Service to adaptively manage the RPA elements as appropriate, and as envisioned by the 2003 Amended BiOp. For example, over the past several years, based on new information or changing environmental conditions, our agencies have convened a plenary process with basin stakeholders to develop technical criteria for the spring pulse, worked collaboratively to modify the definition and parameters of Shallow Water Habitat (SWH), and explored modifications to criteria for unbalancing the upper three reservoirs that will benefit the species without adversely affecting the flood control purpose. All of these adjustments to management actions are based on evaluation of habitat, flow, climate, species response and other information as it becomes available, as contemplated in the 2003 Amended BiOp (pg 221).

Our agencies continue to meet regularly through the established Agency Coordination Team (now known as the CORE team) which allows us to evaluate implementation of management actions alongside the status of the species to ensure sufficient progress is always being made toward avoiding jeopardy and that course corrections are made as needed (pg 223). This is nowhere more evident than in the continuous improvements being made in the design, location, and construction of SWH to benefit the pallid sturgeon. The Corps' implementation teams are incorporating the best available pallid sturgeon science into engineering designs to address the factors thought to be limiting sturgeon success. We will also continue to make use of the quarterly MRRMP/EIS In-Progress Review meetings to jointly resolve management decisions as needed.

As we have agreed, and shared publicly on many occasions, the Corps fully recognizes the need to expeditiously complete the path to a new management plan as agreed to above in order to continue fulfilling our obligations under the ESA.

We look forward to our continued collaboration over the next year to achieve that goal.

David J. Ponganis, Director
Department of the Army
Corps of Engineers, Northwest Division
P.O. Box 2870
Portland, Oregon 97208-2870

Dear Mr. Ponganis:

Thank you for your July 31, 2015 letter concerning the status of consultation regarding the U.S. Army Corps of Engineers (Corps) operation and maintenance of the mainstem Missouri River reservoir system, the Missouri River Bank Stabilization and Navigation Project, and the Kansas Reservoir System. As you point out, our two agencies have been working very closely on a path forward. That path includes the development of a Missouri River Recovery Management Plan and Environmental Impact Statement (MRRMP/EIS). This is being conducted in a highly transparent and public forum through the Missouri River Recovery Implementation Committee (MRRIC). Your letter goes into great detail about the level of scientific and policy involvement that has been ongoing between our agencies and the MRRIC for the last several years. I will not reiterate those efforts here.

It is reasonable to expect that a logical outcome of all of our work will be a Biological Assessment and a new, revised, or amended biological opinion based on the Service's current 2003 Amended Biological Opinion. I concur in your understanding of the status of consultation described in your letter. We will continue to assist the Corps in implementing the current biological opinion, and will continue to support the current process on the MRRMP/EIS. Your letter accurately reflects our understanding about the sequencing or scheduling of these steps. It is imperative that we coordinate the MRRMP/EIS and section 7 consultation obligations, as this coordination is critical to the success of our respective obligations under NEPA and the ESA.

Lastly, I agree with you that time is of the essence. Both from a conservation perspective for the species, as well as administratively, it is in our collective best interest to have a scientifically sound and legally defensible strategy to meet our agency challenges. The work at hand is extensive, requiring both human capital and financial resources from both of our agencies. You have my commitment to assist the Corps in finding efficiencies that do not sacrifice quality as we move forward.

I appreciate all the excellent working relationship that the U.S. Fish and Wildlife Service has with the Corps on the Missouri River. If you have additional questions, please feel free to contact Michael Thabault, Assistant Regional Director at (303) 236-4210.

Sincerely,

Regional Director

October 30, 2017

Michael Thabault
Assistant Regional Director, Ecological Services
U.S. Fish and Wildlife Service
Mountain-Prairie Region
134 Union Blvd.
Lakewood, Colorado 80228

Dear Mr. Thabault:

In accordance with the ongoing Section 7 consultation efforts between our agencies pursuant to the Endangered Species Act (ESA), I am submitting our 2017 Biological Assessment (BA) for the Operation of the Missouri River Mainstem Reservoir System, the Operation and Maintenance of the Bank Stabilization and Navigation Project, the Operation of Kansas River Reservoir System, and the Implementation of the Missouri River Recovery Management Plan. This BA provides the information pursuant to 50 CFR §402.14, documents and incorporates new and additional information not previously provided by the U.S. Army Corps of Engineers (USACE), and describes all of the current and proposed actions of USACE to comply with the ESA.

The 2003 Amended Missouri River Biological Opinion (BiOp) provided a Reasonable and Prudent Alternative (RPA) with management actions to avoid jeopardy to the pallid sturgeon, interior least tern, and piping plover. USACE has diligently dedicated resources to implementing most aspects of the RPA since 2003 and established the Missouri River Recovery Program (MRRP) to enable USACE to meet its congressionally authorized purposes and ESA requirements. The Missouri River Recovery Implementation Committee (MRRIC) was also convened pursuant to Section 5018 of the Water Resources Development Act of 2007 to provide recommendations to USACE and the U.S. Fish and Wildlife Service (USFWS) on these efforts.

Since the issuance of the 2003 Amended BiOp, significant uncertainty remains regarding the science and effectiveness of certain actions, and additional information has become available that supports preparation of this BA.

In accordance with ESA regulations, USACE is reinitiating consultation based on the following new information concerning effects of the proposed action on the aforementioned three species.

- Since the 2000 BiOp and 2003 Amended BiOp were published, a substantial amount of research has generated new knowledge regarding pallid sturgeon lifecycle needs.
- In 2011, the Independent Science Advisory Panel (ISAP), established collaboratively with MRRIC, USACE, and USFWS, published a report concluding that managed spring pulses, as currently designed and implemented, appear to be unnecessary to serve as a spawning cue for pallid sturgeon, do not result in floodplain-channel connectivity, and have not been

successful in scouring emergent sandbar habitat to provide suitable nest sites for least terns and piping plovers.

- The ISAP report also called for an analysis of the effects of USACE management actions on pallid sturgeon including further examination of various flow management actions and their relationship to habitat creation. Based on this report, MRRIC recommended seven actions to USACE and USFWS in August 2012, which are included in the BA.
- An Effects Analysis was initiated in 2013 to synthesize new scientific information specific to these three species and concluded that considerable uncertainty remains regarding the type and extent of management actions ultimately needed to lead to population growth for each of the three species.
- As of 2014, USACE had implemented multiple construction actions for the purposes of providing Shallow Water Habitat (SWH). Including construction of 39 side-channel chutes and 14 backwaters, approximately 11,325 acres of SWH were available from Ponca, Nebraska, to the mouth.
- Development of the Draft Missouri River Recovery Management Plan and Environmental Impact Statement (MRRMP-EIS) was undertaken. The Draft MRRMP-EIS evaluates a range of management actions and alternatives to achieve the purpose of fulfilling USACE responsibilities under ESA. A Final MRRMP-EIS will be published following completion of Section 7 consultation that this BA initiates.
- Development of a Draft Adaptive Management (AM) Plan was initiated. Uncertainty of the science and the effectiveness of the proposed management actions, especially those targeting pallid sturgeon, necessitates they be undertaken within an AM framework that allows flexibility and modifications as new information becomes available. The AM Plan also includes a mechanism for collaboration with states, Tribes, and other stakeholders via MRRIC (this engagement is supplemental to and does not replace existing statutory requirements).
- A Section 7(a)(1) Conservation Plan has been developed that identifies discretionary actions that may be implemented complementary to the other identified by USACE as part of the BA Proposed Action. The Section (a)(1) plan is included as Appendix D to the BA.

The proposed action includes implementation of management actions for the benefit of the pallid sturgeon, least tern, and piping plover within an AM framework, that USACE is committed to follow, and is consistent with all applicable Federal and state laws, Tribal trust responsibilities, and interstate compacts and decrees.

In summary, there is significant new information that USACE has obtained since the issuance of the 2003 Amended BiOp. The proposed action in this BA is the result of careful consideration and evaluation of this new information by USACE, in partnership with the USFWS Mountain-Prairie Region and the MRRIC.

I look forward to engaging in formal consultation with your agency and the timely completion of the consultation process.

David J. Ponganis
Director of Programs Directorate

APR 13 2018

Mr. David J. Ponganis
Director of Programs Directorate
U.S. Army Corps of Engineers, Northwest Division
P.O. Box 2870
Portland, Oregon 97208-2870

Dear Mr. Ponganis:

Please find enclosed the Final Biological Opinion concerning the Operation of the Missouri River Mainstem Reservoir System, the Operation and Maintenance of the Bank Stabilization and Navigation Project, the Operation of Kansas River Reservoir System, and the Implementation of the Missouri River Recovery Management Plan. The U.S. Fish and Wildlife Service (Service) transmitted the draft to the USACE on February 8, 2018 and the USACE subsequently transmitted the draft BiOp to the Independent Science Advisory Panel (ISAP) of the Missouri River Recovery Implementation Committee (MRRIC). The ISAP presented the results of their review to the MRRIC plenary session March 27, 2018 and the USACE formally transmitted the ISAP response along with USACE supporting information to the Service on April 3, 2018. The Service wants to thank the USACE for their continued collaborative approach to what is a ground breaking process of evaluating a highly complex adaptive management process through section 7 of the Endangered Species Act.

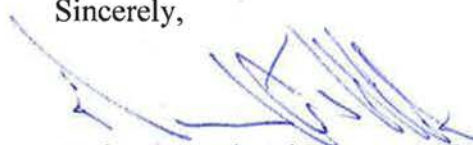

The Service has taken the ISAP and USACE comments under advisement and have made numerous improvements to the document as a result. As you are aware the draft BiOp did not have a fully developed Incidental Take Statement (ITS). The Service provided concept papers to the USACE and MRRIC at the MRRIC plenary session mentioned above. While there was not an explicit charge to the ISAP to review and comment on the ITS both the USACE and the Service received review comments on the ITS on April 4, 2018. In summary the ISAP expressed concern over using survival of pallid sturgeon as the metric for the ITS, particularly in the lower river. Service and USACE staff have been working very closely on addressing ISAP concerns. The Service also continued to engage our fisheries professionals on how to address the ISAP concerns. At the end of the day the Service has concluded to continue to utilize survival estimates of pallid sturgeon as a metric in both the upper and lower Missouri River. However, in light of the ISAP comments the Service has developed a second metric in the lower Missouri river that relies on catch per unit effort as was suggested by the ISAP. Further explanation of the rationale can be found in the Final BiOp. The Service anticipates that as a result of monitoring and evaluation through the adaptive management process refinements to one or both of those metrics is likely.

There remains two process documents that will need to be completed prior to completion of the Record of Decision. The first is a process and procedures document that will describe how subsequent step down consultations will be addressed in the future. The second is a process mechanism for the Service to provide to the USACE a periodic progress review regarding overall implementation of the Final BiOp. Both our staffs are aware of these and will be turning to develop those shortly.

In closing, I would like to thank you and USACE staff for working so closely with the Service on developing a very complex and cutting edge program to further conservation of threatened and endangered species within the Missouri River Basin. The Service firmly believes that this approach will improve conditions for protected species through time while ensuring the USACE's ability to meet the authorized purposes on the Missouri River and allowing better opportunities to address human considerations throughout the basin.

If you have any questions please feel free to contact me at 303-236-4210 or Ms. Kimberly Smith at 303-236-4347.

Sincerely,

Assistant Regional Director – Ecological Services

PREAMBLE¹

BACKGROUND

The Missouri River corridor is approximately 2,315 miles long. Over the course of thousands of years of occupation, Indigenous Peoples have established and maintained cultures and traditions that revolve around the natural resources of, and wildlife attracted by, the Missouri River ecosystem. This ecosystem and its well being continue to be crucial to the worship practices and life ways of contemporary Indigenous Peoples. There is a direct relationship between the environment, traditional worship practices, and the continued survival of diverse indigenous groups. Animals such as the buffalo, eagle, wolf, turtle, migratory and non-migratory birds, a variety of fish and aquatic plants and animals, as well as several species of trees, shrubs, and plants are central to traditional worship beliefs and practices. Within the Missouri River corridor, important natural springs exist which are sacred to Indigenous Peoples and have been considered so for thousands of years.

For Indigenous Tribal Peoples, the Missouri River is characterized as “The Water of Life” and the very water that created the corridor is considered sacred. When the Army Corps of Engineers built six main-stem dams on the Missouri River, life for the Indigenous Peoples who called the River home changed immediately and dramatically. Gone are many of our ancient, river-bottom homes, our medicines, our sacred places, the earthlodge and tipi village and hunting camp sites created by our beloved ancestors. Gone also are many places intrinsic to our origin stories and to events in our oral histories that are alive in our Peoples’ minds and hearts and in stories which are still related today. The loss of our river homes affected every aspect of the quality of our lives: spiritual, mental, physical, emotional, and socio-economic lifeways, all of which make up our very identity as Native Peoples. Altering the flow of the River altered the face of our Mother Earth, and we are still reeling from and dealing with the consequences of these man-made changes.

As a result of the creation of the Missouri River main stem and attendant dams, there are severe threats to many of the remaining sacred places and important resources that traditional Indigenous Cultures require for continuance. These threats include but are not limited to:

- Impacts caused by increasing development expanding out from urban areas (both on and off the water), which has historically been fueled by inadequate planning and management, as well as poor enforcement of applicable laws and regulations.
- The cultural resources, including traditional and sacred places, within the corridor are routinely raided and looted by pot hunters, at night and often from boats, and by ‘vacation archaeologists’ and pothunters who don’t acquire federally required permits.

¹ This Preamble was authored by the Tribes that consulted on this PA. It is not intended to and does not reflect the views of the U.S. Army, Corps of Engineers and may not reflect the views of the consulting parties.

- The waters of the lakes created by the Missouri River dams are constantly eroding the shoreline by ice in winter and wind generated waves in summer, or the raising and lowering of lake levels, in places removing shoreline by up to 30 or more feet per year. This erosion is not only an environmental problem, it also erodes indigenous tribal burial sites, ceremonial sites, and occupation sites. The eroding shoreline is causing the disappearance of many wild gathering and harvesting areas crucial to the continuance of traditional ways of life.
- An increasingly serious siltation problem is forming deltas at the mouths of all drainages flowing into the corridor caused by the lack of free flowing water in the corridor itself.
- The dams have adversely impacted the fish populations, as well as nesting birds, river otters, migratory birds, and many other animal species that relied on the natural rhythms of the river, which directly result in several species being identified as listed, threatened, or endangered. Studies have yet to be completed which identify plant (medicines) species that have been impacted by the dams.
- Investments of cooperative initiatives (Tribal, State and Federal) in the reintroduction of habitat along the riverbanks are seriously impacted by rapid erosion, even those plantings designed to slow or halt erosion.
- Increasing concentrations of chemicals and other pollutants are having an adverse impact on the use of water in all areas of life, including ceremonial activities.

For Indigenous Nations, Cultural Resources include animals, plants, and natural resources, as well as burial, occupation, prayer/worship, gathering, and gardening sites. Cultural Resources from the perspective of land-based worshippers also include important viewsheds, buttes, mountains, high ridges, and other natural formations that do not fit any Federal concepts or definitions. This has been problematic for Tribes and Tribal Peoples who see these resources holistically. In contrast, Federal and State law often segment these resources and assign their well being and management to diverse and, at times, competing Federal or State agencies. Under the National Historic Preservation Act (NHPA), an area that is inhabited by a unique community of plants or animals can be recognized as eligible for the National Register of Historic Places because of its ongoing importance for the culture of a living human community as a traditional cultural property (TCP), but in the implementation of the NHPA, much more attention has been given to sites that contain archaeologically important components. In addition, the importance of these relationships is subject to the interpretation of people and agencies that have no connection to either the archaeological/historic component or the plant/animal component and little understanding of their perceived sacredness by Indigenous Peoples.

This Programmatic Agreement is an attempt to address all problems associated with cultural and historic resource impacts involved with the ongoing operation and maintenance of the Missouri River system of main stem dams. It is by design an initiative that will facilitate the development of processes and strategies to minimize, avoid, or mitigate the ongoing adverse impacts the system causes. It is an attempt to overcome barriers keeping worshippers from areas and resources that are essential to their continuing ability to carry out traditional worship pursuits. Furthermore, through the collective establishment and implementation of principles of Consultation, and Collaboration, and Shared Stewardship, this document will lay the groundwork for Tribes to achieve parity with the Corps of Engineers on issues directly affecting important historic, cultural, and natural resources. Though this document is limited in its scope to the application and enforcement of historic preservation and protection laws, it provides

the opportunity to develop a dialogue and forum for the various Indigenous Nations and Federal agencies to begin addressing all resources considered sacred or important by Indigenous Peoples.

PARADIGM SHIFT

Historically, the Army Corps and the Tribes have experienced difficulties in addressing these issues in a manner that produces positive change and benefits for Tribes. It is time now to affect a shift in the paradigm that has driven the “management” of tribal sacred and cultural places; a substantial change is, in fact, long overdue. Since the 1970s, according to an Army Corps document issued during the Master Manual comment period, a total of \$1.9 million has been spent by the Omaha District Army Corps to stabilize shoreline for a total of 19 archaeological sites on the Missouri River. Recently, the Northwestern Division announced that \$3 million would be available annually to support the Cultural Resources Office of the Omaha District, all of which should be spent to stabilize the shoreline of the most endangered sacred and cultural places. Recently, the Army Corps staff issued a comprehensive list of the most endangered sites on the Missouri River, which comes with a price tag of \$77 million for shoreline stabilization. There is a tremendous disparity between available funds and what is still needed to preserve and protect our remaining cultural resources, and this disparity can only be addressed by an immediate and drastic change in the way our sacred places are cared for and maintained.

The Tribes expect the Corps to manage lands under its jurisdiction in a manner consistent with the Federal trust responsibility to Indian Tribes. The Corps acknowledges that the trust responsibility includes legal responsibilities and obligations to provide the highest standards of fiduciary care with respect to Federal and other activities that may affect the lands, other trust resources, and the exercise of the powers and rights of Indian nations.

All Corps actions, in the Missouri River Basin, directly or indirectly affect trust land, and some of the lands managed by the Corps are within reservation boundaries established by treaties where the Tribes and their members continue to have treaty-based rights even though lands have been taken out of trust status. Federal lands managed by the Corps (both within and outside reservation boundaries) include places that hold religious and cultural importance of the Tribes, and some of these places are crucial for the cultural identities of the Tribes and, as such, for the survival of the Tribes as distinct Peoples. Some of these places contain the graves of ancestors and funerary objects, in which Federal law recognizes the right of lineal descendants and culturally affiliated Tribes to take custody in the event that they are removed from the Earth. The Tribes expect the Corps to treat these sacred and cultural significant places as subject to the Federal trust responsibility.

This means that the Tribes must be engaged in consultation before decisions are made and that the Tribes expect to be equal participants in making decisions and in carrying out decisions. Consultation shall be both specific to individual Tribes and with as many comprehensive consultations attended by all affected Tribes as are necessary, with real efforts to reach consensus. Consultations shall be conducted in a positive manner, on a government-to-government basis, honoring all treaties and the trust doctrine which entail a fiduciary and fiscal responsibility of the Corps. Decisions will be made on a government-to-government basis. Finally, the Corps shall include, as consulting parties, affected Tribes in any review or update of the Master Manual.

The Tribes expect the Corps to exercise genuine stewardship with respect to places that hold religious and cultural importance for the Tribes and to share the stewardship of these special places with the Tribes. Whether this is called “shared stewardship” or “cooperative management” or some other term, the Tribes expect the relationship that develops between the Corps and the Tribes to be respectful and cooperative, with the ultimate objective of protecting these sacred and culturally importance places and assuring access for religious and cultural activities.

Finally, the Tribes anticipate that this shared stewardship document will ensure that our sacred and cultural places are regarded and understood from a native viewpoint with our values and customs applied to their protection, and not necessarily those of archaeology. For decades, the perceived archaeological value of our sacred places has been the only viewpoint considered, and that method of assigning value to our holy places has contributed to a recipe for their destruction: mix equal parts erosion, neglect and development; let this mixture ‘rest’ for fifty years, add a measure of ‘salvage archaeology,’ destroying the sites to extract data; let the rest fall into the water. And you have a meal that is unfit to eat for Native peoples, a meal which we have been force-fed since the 1930’s, when construction of the first dam near the Ft. Peck Reservation was begun.

The Tribes expect that in the new paradigm, the fundamental value will be respect: respect for the River and for our sacred and cultural places; respect for our values, our culture, our beliefs; respect for Native Peoples and our contributions to the upper Missouri River environment; as well as respect for the tremendous sacrifices we made so that newcomers to our homelands could have flood control and electricity. We want to be taken seriously when we talk about our cultures, our needs, and our issues—and we want to be taken as seriously as archeologists are when they talk about our ancestors, our cultures, and our interests. And that is the second half of the paradigm shift our Nations are all working toward: to bring our interests and issues, articulated from our value system and from our point of view, to a ‘key issue’ priority level with the Omaha District of the Army Corps so that they receive the same attention and resources as other issues for which the Corps has responsibility. We know that what we want is not unreasonable. We also know that the Programmatic Agreement holds great potential to improve relations between the Missouri River Tribes and the Army Corps, and can be the tool we use to create a success story of which we can all be proud.

**PROGRAMMATIC AGREEMENT
FOR THE
OPERATION AND MANAGEMENT OF THE MISSOURI RIVER
MAIN STEM SYSTEM
FOR
COMPLIANCE WITH THE NATIONAL HISTORIC PRESERVATION ACT**

WHEREAS, the Omaha District and the Northwestern Division of the U.S. Army Corps of Engineers, (hereinafter the Corps) operate and manage the integrated system of multi-purpose reservoir projects and associated structures and lands on the Main Stem of the Missouri River for flood control, navigation, irrigation, municipal and industrial use, recreation, fish and wildlife protection, and other purposes as authorized by the Flood Control Act of 1944 (P.L. 78-543, as amended) and other relevant authorities; and

WHEREAS, the Corps' authorized operation and management of impounded waters of the Main Stem System results in adverse effects to properties included in or eligible for the National Register of Historic Places (hereinafter, historic properties) through inundation, erosion, exposure, and other factors; and

WHEREAS, the Corps' authorized management of project lands that are not routinely inundated or periodically inundated, including land-based support facilities for water control, facilities and measures for recreation, general public use, access, and the enhancement of the environment, fish and wildlife, and other authorized purposes may result in direct and indirect effects to historic properties such as damage or destruction from construction, burning, erosion, sedimentation, theft, looting, vandalism, and other factors; and

WHEREAS, the Corps is responsible for complying with the National Historic Preservation Act, as amended (hereinafter, NHPA) (P.L. 89-665, as amended; 16 U.S.C. 470f), including Section 110 that requires federal agencies 1) to establish a program to preserve, protect, identify, evaluate, and nominate historic properties under their jurisdiction or control (including traditional cultural properties (TCPs) and historic properties to which Tribes attach religious and cultural significance) in consultation with others and 2) to give full consideration to the preservation of historic properties not under their jurisdiction or control but affected by federal agency undertakings; and

WHEREAS, the Corps' Main Stem System operations and management actions meet the definition of undertakings for the purposes of Section 106 of the NHPA (16 U.S.C. 470f) (hereinafter Section 106) and, therefore, the Corps is responsible for complying with Section 106 for these actions; and

WHEREAS, in compliance with Section 106, the Corps, Indian Tribes (hereinafter Affected Tribes), Tribal Historic Preservation Officers (hereinafter, THPOs) and State Historic Preservation Officers (hereinafter, SHPOs), the Advisory Council on Historic Preservation (hereinafter, ACHP) and other consulting parties have developed and the Corps will implement this Programmatic Agreement (PA) in accordance with 36 CFR Section 800.14(b) for certain of the Corps' operation and management actions as outlined in this PA; and

STIPULATIONS

Final Programmatic Agreement
March 19, 2004

WHEREAS, the Corps is required by Section 101(d)(6) of the NHPA to consult with any Indian tribe that attaches religious and cultural significance to historic properties that may be affected by a proposed federal undertaking subject to Section 106; and

WHEREAS, the United States Department of Defense recognizes its trust responsibilities to federally recognized Indian Tribes and has established an American Indian and Native Alaskan Trust policy that directs Department of Defense agencies, including the U.S Army Corps of Engineers, to work with Tribes in a manner that incorporates tribal needs, traditional resources, stewardship practices, and the development of viable working relationships; and

WHEREAS, the ACHP recognizes its trust responsibility to federally recognized Tribes and has described this trust responsibility in its, "ACHP Policy Statement Regarding ACHPs Relationship with Indian Tribes", issued November 17, 2000 and updated on April 4, 2003; and

WHEREAS, the Corps recognizes that sacred and cultural resources, many of which are historic properties, are critically important to the Affected Tribes for the continuity and revitalization of cultural and spiritual life-ways, making avoidance of adverse effects to these resources and the preservation of remaining sacred and cultural places a matter of the highest priority regardless of their eligibility to the National Register of Historic Places; and

WHEREAS, in addition to the NHPA, the Corps is responsible for compliance with other applicable legal authorities outlined in Attachment 1 to this PA that may overlap with or be supportive of the goals and purview of the NHPA and,

WHEREAS, the Corps has provided the opportunity to consult on the development of and to become a signatory to this PA to the ACHP; SHPOs of Montana, North Dakota, South Dakota, and Nebraska; Standing Rock Sioux Tribe and its Tribal Historic Preservation Officer (THPO); Cheyenne River Sioux Tribe and its THPO; Santee Sioux Tribe; Yankton Sioux Tribe; Crow Creek Sioux Tribe; Lower Brule Sioux Indian Tribe; Three Affiliated Tribes; the Assiniboine and Sioux Tribe of Fort Peck; Turtle Mountain Band of the Chippewa Tribe and its THPO; Blackfeet Tribe; Chippewa Cree Tribe; Crow Nation; Flandreau Santee Sioux Tribe; Gros Ventre and Assiniboine Tribe; Northern Arapaho Tribe; Northern Cheyenne Tribe; Oglala Sioux Tribe; Omaha Tribe of Nebraska; Ponca Tribe of Nebraska; Rosebud Sioux Tribe; Sisseton-Wahpeton Sioux Tribe; Spirit Lake Sioux Tribe; Sac and Fox of Missouri in Kansas and Nebraska; South Dakota Department of Game Fish and Parks (SDGFP); Bureau of Indian Affairs (BIA); and the National Trust for Historic Preservation (NTHP) (hereinafter consulting parties).

NOW, THEREFORE, the above parties agree that the Missouri River Main Stem System shall be administered in accordance with the following stipulations to avoid, minimize, or mitigate adverse effects and satisfy the Corps' Section 106 responsibilities for those actions outlined within this PA.

STIPULATIONS

The Corps shall ensure the following measures are implemented:

1. Definitions.

The list of definitions used in this Programmatic Agreement is provided in Attachment 2.

2. 1993 Programmatic Agreement

The Programmatic Agreement for the Missouri River Main Stem System previously executed by the ACHP, Corps and SHPOs from Nebraska, South Dakota, North Dakota and Montana on October 18, 1993 is null and void.

3. Scope of this Programmatic Agreement

A) The geographical scope of this PA, based on the Corps' concept of the Area of Potential Effects, is as follows:

- i) federal lands, owned by the Corps, beginning at the headwaters of Fort Peck Lake, approximately 3 miles northwest of the Fred Robinson Bridge, Phillips County, Montana to Gavins Point Dam, Yankton County, South Dakota, including but not limited to Fort Peck Lake and Fort Peck Dam; Lake Sakakawea and Garrison Dam; Lake Oahe and Oahe Dam; Lake Sharpe and Big Bend Dam; Lake Francis Case and Fort Randall Dam; and Lewis and Clark Lake and Gavins Point Dam with project lands and related structures, generally known as the Missouri River Main Stem System; and
- ii) areas downstream of and adjacent to the six Main Stem dams (which are affected by the operation of the system) are within the geographical scope of this PA, even though these areas are not under the authority or ownership of the Corps and may not be in federal ownership. It is recognized that the Corps has restrictions on its use of Main Stem operations monies and other authorities on non-Corps lands.

B) The Corps shall comply with Section 106 in accordance with 36 CFR part 800 for the following activities:

- i) Projects, activities, policies by or authorized by the state of South Dakota and/or the Corps on so-called Title VI lands, e.g., lands transferred to the SDGFP pursuant to Title VI of the Water Resources Development Act of 1999, as amended (Title VI hereinafter), as the Corps will begin consultation on the development and implementation of a separate PA for these actions in accordance with 36 CFR Section 800.14(b) by December 2004.
- ii) Corps lands or exchanges, including those pursuant to Title VI;
- iii) Corps regulatory actions pursuant to Section 404 of the Clean Water Act.

4. Relationship to Treaties, Statutes, Regulations, Executive Orders, Court Orders, and Other Authorities

A) In general, nothing in this PA diminishes or affects any treaty right of an Indian tribe, any water right of an Indian tribe, or any other right of an Indian Tribe, any external boundary of an Indian reservation of an Indian Tribe; any authority of the States that are a party to this PA; any authority of the Corps or the head of any other federal agency under a law in effect on the date of signing of this PA; any treaty or water right, or any other right of an entity that is not a party to the PA.

B) No provision of this section or of the PA shall limit any right of an Affected Tribe or other consulting party to bring an action against the Corps or any other party once final agency action is complete; shall alter existing law regarding the sovereign immunity of the Tribes, the other consulting parties, or the Corps, or any other entity that is not a part of this PA; or shall be construed to alter existing law regarding the trust duty of the United States or the Corps to the Tribes (either to limit or expand that trust duty).

C) All court orders, including settlement agreements (present and future), shall be implemented and their terms be incorporated into documents and measures or revisions to them called for in this PA. In any case of difference or ambiguity, a court order shall take precedence over the terms of this PA.

5. Programmatic Agreement Coordination.

A) Designated PA Representative(s). Within 60 days of signing this PA, each Affected Tribe and THPO, ACHP, SHPO, and other consulting party shall designate a point of contact for carrying out this PA (hereinafter, PA representative). If more than one person is designated as PA representatives, the party also shall indicate the responsibilities of each such person for carrying out this PA.

B) Government/Personnel Changes. Affected Tribes and THPOs, SHPOs, ACHP, and other consulting parties shall provide timely written notification to the Corps and the other parties to this PA of changes in their tribal or agency leadership (tribal Chairman or President; head of agency, etc.), persons holding cultural and historic preservation positions, and PA representatives.

6. Consultation.

All consultation and coordination required under this PA shall be conducted in accordance with the following:

A) General. The Corps shall plan consultations to coordinate with the requirements of all applicable statutes and executive orders. Affected Tribes and THPOs, SHPOs, ACHP and other consulting parties shall be provided the opportunity to participate in the development and implementation of agreements, management plans, and activities developed or required under this PA. The Corps, Affected Tribes and THPOs, SHPOs, and other consulting parties shall facilitate and cooperate in the consultation process toward the mutual goal of information sharing and promotion of respect.

B) Review and Response Requirements. Unless otherwise provided for in this PA, the Corps shall afford the Affected Tribes and THPOs, SHPOs, ACHP, and other consulting parties no less than 30 calendar days from receipt of a complete consultation request to respond to a Corps communication required under this PA. A complete consultation request shall include information that the party determines is needed to make an informed decision on the matter. Should any Affected Tribe or THPO, SHPO, or other consulting party not respond within this time limit or other limit specified elsewhere in the PA, the Corps will document in its records when consultation was requested and the non-response. Unless an Affected Tribe or THPO, SHPO, or other consulting party responds in writing that it does not wish to consult at all on the proposed undertaking or matter, the Corps shall assume that the party wishes to continue consulting on subsequent requests related to that initial undertaking or matter. Failure to respond will not be construed as either concurrence or non-concurrence.

C) Pre-Consultation Actions. To promote effective and meaningful consultation, the Corps shall notify the Affected Tribes and THPOs, SHPOs, ACHP, and other consulting parties of the need to consult on the various matters called for in this PA as soon as possible and pre-decisionally as follows:

- i) provide a notification letter with information about the proposed undertaking or matter to each PA representative, with a copy to the head of the agency or tribal government, as early as possible and prior to making any decisions about the proposed undertaking or matter;
- ii) follow-up via telephone with the PA representative after distributing the notification letter to establish a person-to-person contact;
- iii) provide further information as the PA representative may need for informed input and judgment;
- iv) provide draft agendas, request input from the PA representative, and finalize the agenda based on this input;
- v) coordinate consultation for this PA with consultation requirements for other legal bases to the extent possible and inform the PA representative of all pertinent legal bases for consultation.

D) Consultation Guidelines. For meaningful and effective consultation with the Affected Tribes and THPOs, SHPOs, ACHP, and other consulting parties, the Corps shall

- i) Listen carefully before any decisions are made so as to understand the needs and perspectives of the Affected Tribes and THPOs, SHPOs, ACHP, and other consulting parties;
- ii) Work as equal partners with the Affected Tribes and THPOs, SHPOs, ACHP, and other consulting parties to consider and devise means to identify and preserve cultural resource sites and avoid effects to them, consistent with tribal viewpoints and values. If avoidance is not possible, the Corps shall work with the Affected Tribes and THPOs, SHPOs, ACHP, and other consulting parties as equal partners to minimize effects to such sites to the greatest extent possible;
- iii) Provide all pertinent documents and other information, consistent with Federal law, to the Affected Tribes and THPOs, SHPOs, ACHP,

and other consulting parties to enable fully informed decisions and meaningful consultation;

- iv) Plan consultations jointly with the Affected Tribes and THPOs, SHPOs, ACHP, and other consulting parties, including meetings (when and where), conference calls, agendas based on requested input from all involved.
- v) Engage in consultation to discuss, dialogue, and make agreements, and do so through face-to-face consultation meetings to the greatest extent possible;
- vi) Make and provide written accurate records of all consultations and make copies available to Affected Tribes and THPOs, SHPOs, ACHP and other consulting parties within 30 days of the consultation. Written verbatim records will be made utilizing a court reporter, on a case-by-case basis when requested by a signatory for a face-to-face consultation. When requested by a signatory, verbatim records of telephone conference calls may be made by using a tape recorder, and copies of the tape provided to the requesting signatory. Affected Tribes and THPOs, SHPOs, ACHP and other consulting parties shall have the opportunity to review, offer corrections, and add alternative views to the record;
- vii) the federal agencies, affected tribes, THPOs, SHPOs, and other consulting parties shall facilitate and cooperate in the consultation process toward the mutual goal of information sharing, promotion, and respect for the unique relationship of each party and the trust doctrine and trust responsibility of the federal parties.

E) Input from Tribal Elders. An Affected Tribe or THPO, SHPO, or other consulting party may respond to a request by informing the Corps that special efforts should be made to seek input from tribal elders and other persons with traditional and cultural knowledge. If the Corps is so notified or if persons with traditional or cultural knowledge notify the Corps that they wish to be consulted regarding a matter, the Corps shall consult with the Tribe and/or THPO regarding appropriate ways to seek input from such persons, and the Corps shall seek such input. Efforts may include (but need not be limited to) conducting special meetings, scheduling meetings at locations to reduce the need for such persons to travel, ensuring that translation services are available, and adjusting the schedule to accommodate input from such persons.

F) Protocol Agreements. The Corps recognizes that an Affected Tribe, THPO, SHPO, or other consulting party may have particular issues of concern, ways of conducting business, or protocols that should be considered during consultations. When requested by an officially designated representative or PA representative, the Corps and that party shall cooperatively develop a Protocol Agreement (PRAG) to document that agreed-upon protocol. A PRAG shall be supplemental to the general procedure(s) in this PA and not modify the roles of other parties to this PA without their prior written consent.

G) Efficient Consultations. The Corps and the Affected Tribes and THPOs, SHPOs, ACHP, and other consulting parties shall work together to develop ways to communicate and transmit information in an effective yet efficient manner. Possible means include (but are not limited to) development of a secure website to which the Affected Tribes and THPOs, SHPOs, ACHP and other consulting

parties have access, electronic transmission of documents, and/or an email broadcast system.

7. Non-National Historic Preservation Act Commitments.

In consultation with the Affected Tribes and THPOs, the Corps agrees to carry out the actions outlined in Attachment 3 of this PA, all of which are beyond the requirements of the NHPA and the authority of the ACHP and are under the authority of the laws and legal requirements cited therein.

8. Undertakings Review Provisions; Tribal or SHPO Non-Signature, Withdrawal, or Termination; and Exempt Undertakings.

A) Undertakings Review. For Corps undertakings that are planned or anticipated (for example, but not limited to, recreational and other development, silt or sediment removal, habitat creation or restoration, etc.), the Corps shall consult on and address effects to historic properties through the Five-Year Plan, CRMPs, and attendant Treatment Plans as outlined in stipulations 6, 8, 9, and 11 and the other provisions of this PA. However, for those planned or anticipated undertakings not addressed through the Five-Year Plan, CRMPs, and Treatment Plans, the Corps shall comply with section 106, NHPA in accordance with 36 CFR part 800, subpart B. For Main Stem System operations and their indirect adverse effects (including, but not limited to, erosion, exposure, susceptibility to looting or vandalism, etc.), the Corps shall consult regarding and address such effects to historic properties through the terms of this PA.

B) Tribal or SHPO Non-Signature, Withdrawal, or Termination. The Corps shall comply with Section 106 in accordance with 36 CFR part 800, subpart B for Corps undertakings that may affect lands, or historic properties, many of which are cultural resources sacred to Tribes, located within the exterior boundaries of an Indian reservation, including Corps lands, if that tribe is not a signatory to this PA or if that tribe has withdrawn from this PA or terminated this PA on its tribal lands (refer to Stipulation 4). Similarly, the Corps shall comply with 36 CFR part 800, subpart B for actions or undertakings within a SHPO's area of jurisdiction, if that SHPO has withdrawn from this PA or terminated this PA within its area of jurisdiction.

C) Exempt Undertakings. The Corps, Affected Tribes and THPOs, SHPOs, ACHP, and other consulting parties shall consult to determine if there are certain types of undertakings and actions that should be exempted from review and consultation under this PA because they have little or no potential to affect historic properties. In consulting on this list of exempt undertakings and actions, the Corps shall follow the consultation provisions of stipulation 6 of this PA. The exempt actions and undertakings in such a list shall not go into effect until agreed to, in writing, by the Corps, tribal signatories, SHPOs, and ACHP. The resulting list of exempt undertakings shall be provided to all Affected Tribes and THPOs, SHPOs, ACHP, and other consulting parties as an amendment to this PA.

9. Main Stem Reservoir Cultural Resource Management Plans.

A) Status. The Corps has completed the Lewis and Clark Lake, Lake Sharpe and Lake Francis Case Cultural Resources Management Plans (CRMP), and is in the process of completing the Lake Oahe, Fort Peck Lake and Lake Sakakawea CRMPs. The Corps shall ensure that CRMPs for all Main Stem reservoirs are completed by May 2005 and are developed in consultation with the Affected Tribes and THPOs, SHPOs, ACHP and other consulting parties to this PA.

B) Requirements. The CRMPs will partially fulfill the requirements of the NHPA, this PA, and the requirements of Engineer Regulation 1130-2-540. The CRMPs will provide baseline information about cultural resource sites (including historic properties) at each reservoir and a list of actions to address the goals, objective, and program areas set forth in the Five-Year Plan. The CRMPs will utilize the Lake Sharpe CRMP as a template or any revision to that template developed in consultation with the Affected Tribes, THPOs, SHPOs, ACHP, and other consulting parties. Recommended actions (i.e., TCP surveys, archeological surveys, testing and evaluations, etc.) from CRMP shall be completed in accordance with applicable federal laws governing such actions.

C) Review. The Corps and the Affected Tribes and THPOs, SHPOs, ACHP and other consulting parties shall work together to develop and implement a process by which the Affected Tribes and THPOs, SHPOs, ACHP and other consulting parties will be involved in the development and review of draft and final CRMPs and updates to them. Until completion of this process, drafts of the CRMPs and updates of them shall be provided for review and consultation according to the procedures outlined in stipulation 6, except that parties shall have no less than 60 days for review and comment. To facilitate review, the Corps shall provide Affected Tribes and THPOs, SHPOs, ACHP and other consulting parties with related historic property and management information, such as future management actions, needs, and policies; project maps and information showing historic properties, management/use areas, cultural resources survey coverage, leased areas, recreation areas, boundaries of Corps lands, Title VI lands, and so forth. The Corps shall incorporate comments from the Affected Tribes and THPOs, SHPOs, ACHP and other consulting parties in finalizing the draft or final CRMPs. After review and comment by the appropriate Affected Tribes and THPOs, SHPOs, ACHP and other consulting parties, the Corps shall ensure that the CRMPs are finalized and implemented.

D) Revision. The Corps agrees to update the completed CRMPs every two years. The intent is to monitor progress, incorporate new information, correct information, and allow for additional input into the implementation of the cultural resources program at the reservoir for which the CRMP is written. The review process outlined in stipulation 9.C., above will be used for revising CRMPs.

10. Five-Year Cultural Resources Implementation Plan.

The Corps, working cooperatively and in consultation with the Affected Tribes and THPOs, SHPOs, ACHP and other consulting parties, shall develop and carry out a plan that outlines how the Corps will conduct its Main Stem System Cultural Resources Program and its various program components individually called for in this PA for the coming five years (hereinafter, Five-Year Plan) and following five year periods

thereafter. The intent of the Corps is to incorporate the final Five-Year Plan into the Corps' Strategic Plan.

A) The Five-Year Plan shall describe the following:

- i) actions to identify Mainstem System cultural resource sites (including historic properties) and evaluate them for the National Register of Historic Places that may be affected by Corps undertakings and operations of the Main Stem System and to comply with Section 110, NHPA. Acreage estimates and locations, prioritization of these locations, and tasks (e.g., oral histories, documentary research, etc.) should be described. (See also stipulation 11);
- ii) Corps management and operational actions that may adversely affect historic properties (for example, operations, recreational development, habitat restoration/creation, susceptibility to erosion, looting and vandalism, etc.) and their locations; and
- iii) actions to avoid, minimize, or mitigate adverse effects on historic properties, including identification of specific sites and proposed treatment (subject to consultation with Affected Tribes and THPOs, SHPOs, ACHP, and other consulting parties). (See also stipulation 11);
- iv) actions to address potential effects of Corps operations to historic properties located off Corps lands in compliance with Section 110(a)(2)(c), NHPA, recognizing that the Corps may need to seek alternative funding approaches, special authorizations, appropriations, and/or resolution of property permission issues. (See also stipulation 11);
- v) actions to address unexpected discoveries of historic properties or unexpected effects to known historic properties. (See also stipulation 11);
- vi) actions for the management, analysis, and sharing of cultural resource data, including development of protocol to protect sensitive information (See also stipulations 10 and 17);
- vii) actions to support the cultural resources law enforcement program. (See also stipulation 14);
- viii) actions to monitor cultural resources sites, how site-monitoring information will be used for management purposes, and sites selected to be monitored. (See also stipulation 13);
- ix) actions to develop and update CRMPs, Five-Year Plans, and Annual Reports. (See also stipulations 9, 10, 22);
- x) actions to promote public education and interpretive initiatives and the use of historic properties. (See also stipulation 15); and

xi) other actions and program needs that the Affected Tribes or THPOs, SHPOs, ACHP, or other consulting parties have requested in the Five-Year Plan.

B) Development, Review, and Revision of Five-Year Plan. Within 180 days of the execution of this PA, the Corps shall provide a preliminary draft version of the Five-Year Plan to the Affected Tribes and THPOs, SHPOs, ACHP, and other consulting parties. Then, the Corps and these parties shall work together as outlined in stipulation 6 to develop a draft version of the Five-Year Plan for review. The Corps, in consultation with the Affected Tribes and THPOs, SHPOs, ACHP, and other consulting parties, shall develop a final Five-Year Plan within 120 days of submission of comments on the draft Five-Year Plan. The Affected Tribes and THPOs, SHPOs, ACHP, and other consulting parties shall be given a 60-day review and comment period for each version. The Corps shall incorporate comments received in developing, finalizing, and implementing the Five-Year Plan. Every five years, the Corps shall revise and update the Five-Year Plan using this same development, review, and consultation procedure.

11. Identification of Historic Properties.

A) Identification Activities. The Corps shall identify historic properties (including historic properties to which an Affected Tribe attaches religious and cultural significance, traditional cultural properties (TCPs), and other types of cultural resources), in compliance with Section 110 of the NHPA and the Corps' ER and EP 1130-2-540. Additionally, the Corps shall ensure that historic properties are identified prior to making decisions about undertakings, following the review process outlined in stipulation 8.A. Identification methods to be used include (but are not limited to) pedestrian surveys and other field investigations; background and documentary research; oral histories; tribal consultation and consultation with tribal elders; and other means. The Corps shall evaluate whether properties are eligible for the National Register of Historic Places using the eligibility criteria and National Park Service guidance (including Bulletin 38), in consultation with the SHPO and/or THPO with jurisdiction and Affected Tribes that may attach religious and cultural significance.

B) Location and Recordation of Sites. The Corps shall locate sites by global positioning system (GPS), complete site visit forms, and add site information to the Corps cultural resources site GIS system. Additionally, the condition and threats to sites will be recorded through the site-monitoring program and added to the GIS system. All site identification and monitoring information shall be included in next update of the applicable CRMP.

C) Sharing of Data. Within 120 days of the execution this PA and regularly thereafter, the Corps shall provide existing and updated cultural resource site information in accepted formats or access to the Corps' cultural resources site GIS system to federal, state, and tribal offices charged with maintaining such information.

D) Traditional Cultural Property (TCP) Surveys. The Corps shall ensure that surveys and related efforts (e.g., oral history, etc.) for TCPs and other historic properties to which Affected Tribes may attach religious and cultural or

other significance are carried out for project areas identified in the CRMPs and Five-Year Plan. The results of the surveys and other efforts shall be documented using National Park Service Bulletin 38, as well as other pertinent tribal and state requirements, with sensitive information protected pursuant to stipulation 17.

12. Measures to Avoid, Minimize, or Mitigate Adverse Effects to Historic Properties.

Prior to carrying out measures to avoid, minimize, or mitigate adverse effects to a historic property as set forth in the Five-Year Plan and CRMPs, the Corps shall provide a draft Treatment Plan to the Affected Tribes and THPOs, SHPOs, ACHP, and other consulting parties for review and consultation as outlined in stipulation 6. Alternatively, a draft Treatment Plan may be included in a draft CRMP or draft Five-Year Plan and be reviewed as part of those draft documents. The draft Treatment Plans shall describe the historic property and the adverse effects to it, alternatives measures considered, treatment proposed and why it was chosen, details of how treatment will be implemented, schedule and cost of proposed treatment, and how the treatment meets the pertinent standards and guidelines of the *Secretary of the Interior's Standards and Guidelines for Historic Preservation Projects*, and applicable state and tribal requirements.

13. Site Monitoring Program

A) Site Monitoring. The Corps shall develop and implement a monitoring program to provide continued oversight of historic properties located on federal land managed by the Corps and to collect information on site conditions and effects or threats to them (including but not limited to, erosion, recreational, agricultural and other encroachment, and looting and vandalism). The Corps shall use this information to plan and implement law enforcement and other preventive or corrective management actions.

B) Site Monitoring Plan. The Corps shall develop a Monitoring Plan to describe the conduct of the monitoring program. The Plan shall discuss the types and location of sites to be monitored, field methodology of monitoring and conditions recordation (including forms, data dictionary); data storage, retrieval and analysis; schedule; staffing and qualifications; and other details. The Corps shall produce a preliminary draft and then the Corps, Affected Tribes and THPOs, SHPOs, ACHP, and other consulting parties shall work together to develop a draft version of the Monitoring Plan, in accordance with stipulation 6. The Corps, in consultation with the Affected Tribes and THPOs, SHPOs, ACHP, and other consulting parties shall develop a final monitoring plan within 180 days of submission of comments on the draft Monitoring Plan. The Corps shall implement the final monitoring plan according to the schedule in the monitoring plan, CRMPs, and in response to recent information about potential threats to sites.

14. Enforcement Program.

A) Enforcement Memorandum of Agreement(s) (MOA(s)).

The Corps, in cooperation with the local, state, tribal and federal law enforcement officials, shall develop an Enforcement MOA(s) that provides for a cultural resources enforcement program to address looting, vandalism, and other

illegal activity involving cultural resource sites, including TCPs, archeological resources, graves, and human remains. Specifically, the Enforcement MOA(s) shall address laws, authorities, potential cross-authorities, delegations and deputization of authorities, fine distribution, field deployment, access, sharing of equipment, public education, information reporting, gathering and exchange, and other issues. The Corps shall provide a draft Enforcement MOA for review to all interested parties, including law enforcement officials and Affected Tribes, THPOs, SHPOs, ACHP, and other consulting parties, within 60 days of the signing of this PA. The Corps shall work with the interested parties to revise the draft Enforcement MOA to address their comments. The Enforcement MOA shall be finalized only after the consultation process has been completed as stated in stipulation 6.

B) Hotline. Within 120 days of the signing of this PA, the Corps shall establish and promote a hotline for reporting of looting, vandalism, and other illegal activities and a specific protocol for documentation, verification, and tracking of information, for the purpose of prosecution of offenders.

C) ARPA Training. Every three years the Corps shall host an ARPA training class for law enforcement, cultural preservation personnel (tribal, state and federal), and others who may be involved in enforcement activities.

15. Cultural Resource Education Program.

A) Educational Program. Engineer Regulation No. 1130-2-540 authorizes the preparation of brochures, slide shows, or other media documentation for public presentation relative to historic preservation activities that may be of particular interest to the Affected Tribes and general public.

i) The Corps shall create educational displays, media shows, interpretive programs, pamphlets, and brochures to enhance public education concerning cultural resources. The parties to this PA will be involved in the development and finalization of these items. The Five-Year Plan and CRMPs will describe how the Corps will carry out this educational and interpretive program.

ii) The Corps, in consultation with the Affected Tribes and THPOs, SHPOs, and as outlined in the CRMPs and Five-Year Plan, will develop an educational program concerning the need to avoid cultural areas and to leave archaeological sites and their material remains undisturbed. The public is generally uninformed about the significance of cultural resources and unaware of the significance of these cultural areas or sites for Affected Tribes whose ancestors lived in these areas and created what are often referred to as archaeological sites.

B) Signage. The public must be made aware that cultural sites are being monitored for unauthorized activities and severe criminal penalties could result from illegal activity of looting, artifact collecting, and vandalism. The Corps, in consultation with Affected Tribes and THPOs, SHPOs, ACHP, and other consulting parties, shall develop and place signs at agreed upon points of public access to the Missouri River.

C) Press Release. In consultation with Affected Tribes and THPOs and SHPOs, the Corps shall issue press releases and conduct press conferences bi-annually (Spring and Fall) to remind the public about the penalties associated with looting, artifact collecting, and vandalizing. A list of local, regional, and multi-state media will be developed in consultation with Affected Tribes and THPOs, and SHPOs.

16. Curation of Artifact Collections, Material, Records, and Data.

The Corps shall ensure that artifacts are collected on a minimal basis only in those situations that require the collection to support a requirement of the NHPA.

The Corps shall curate artifact collections, material, records, and data according to 36 CFR Part 79.1-Curation of Federally-owned and Administered Archeological Collections and Corps Engineer Regulation 1130-2-433, except that resources meeting NAGPRA definitions will be handled according to the requirements and procedures in the NAGPRA regulations or other memoranda of agreement entered into between the Corps and tribal governments. The Corps shall curate paleontology resources as addressed in Attachment 3. The Corps will continue to carry out its current practice of reburying artifacts on or near the area where they were found during monitoring or other field actions, and their discovery and subsequent reburial will be reported to the Affected Tribes

17. Protection of Sensitive Information.

A) Legal Background. Section 9 of ARPA provides for information concerning the nature and location of archaeological resources on federal land and Indian land to be protected from disclosure under the Freedom of Information Act (FOIA), unless excepted under ARPA. Section 304, NHPA provides that information about the location, character, or ownership of a historic property shall be withheld from disclosure under FOIA if the Corps, in consultation with the National Park Service, determines that disclosure may 1) cause a significant invasion of privacy; 2) risk harm to the historic resource; or 3) impede the use of a traditional religious site by practitioners. The Corps, to the maximum degree possible, shall respect section 9 of ARPA and section 304 of the NHPA in determining *the* release or disclosure of information under FOIA. For the purposes of protection of sensitive information, the Corps shall consider properties or locations that have not been evaluated for their National Register eligibility, including TCPs and properties of religious and cultural significance, as eligible for the National Register in making this determination.

B) Confidentiality Protocol. The Corps and Affected Tribes, THPOs, SHPOs, ACHP, and other consulting parties recognize the need to treat certain kinds of sensitive or proprietary information with confidentiality, including but not limited to information about the location of places that hold sacred significance for Affected Tribes and THPOs. The Corps and Affected Tribes, THPOs, SHPOs, ACHP, and other consulting parties shall, working in close consultation as outlined in stipulation 6, and assuring compliance with Federal and other applicable law, develop a protocol for the confidentiality of such sensitive information within one-year of signing of this document.

C) Interim Confidentiality Provisions. Until such a protocol is adopted, the Corps and Affected Tribes, THPOs, SHPOs, ACHP, and other consulting parties shall protect information concerning the nature, character, ownership, or location of archaeological resources or historic properties and withhold such information from disclosure to the public as outlined in subsection A) above of this stipulation. Also, the Corps shall ensure that each document that includes information about any historic property, archaeological resource, or unevaluated location shall be accompanied with a prominent notice that the document and information are to be treated for official use only.

18. Corps Main Stem System Operations Decision Documents.

The Corps shall consult with Affected Tribes and THPOs, SHPOs, ACHP, and the other consulting parties on draft Annual Operating Plans and other decision documents to determine whether operational changes are likely to cause changes to the nature, location, or severity of adverse effects to historic properties or to the types of historic properties affected and whether amendments to the Corps' CRMP(s) and Five-Year Plan are warranted in order to better address such effects to historic properties.

19. Tribal Partnerships.

The Corps and the Affected Tribes, THPOs, SHPOs, ACHP shall work together to develop and implement partnerships so that Affected Tribes, THPOs, SHPOs, ACHP are involved in the development and implementation of the Main Stem System cultural resources program and this PA and that promote tribal historic preservation goals. Training, access to cultural resource site information (subject to provisions for protection of such information), historic preservation services, sharing of and/of access to equipment, etc. may be the basis of such partnerships. It is acknowledged that some or all these partnerships may need to be supported by cooperative agreements or other instruments to be negotiated independent of this PA. Additionally, if requested by an Affected Tribe, the Corps shall consult regarding the possibility of tribal access to historic properties that are sacred to the Affected Tribe and THPOs on Corps lands, in fulfillment of Executive Order 13007 and the Corps' EP 1165-2-1, section 3-2. Further, the Corps shall consult with Affected Tribes, THPOs, SHPOs, ACHP regarding the Corps' Tribal Partnership Program established pursuant to Section 203, Water Resources Development Act of 2000.

20. National Historic Preservation Act/Native American Graves Protection and Repatriation Act Overlap.

The Corps shall comply with Sections 106 and Section 101(d)(6) of the NHPA and the Native American Graves Protection and Repatriation Act (NAGPRA) in circumstances in which both authorities apply, such as the discovery of human remains that may be associated with a historic property. In addition to complying with NAGPRA, the Corps shall take steps to identify if human remains and other types of items meeting the definitions outlined in NAGPRA are associated with a property that may meet the National Register criteria and for which Section 106 and Section 101(d)(6) also apply. In such case, the Corps shall comply with the provisions of this PA and 36 CFR part 800, in addition to NAGPRA and any applicable NAGPRA Memoranda of Agreement (see Attachment 3).

21. Performance Standards and Qualifications.

A) Standards. The Corps shall ensure that all work required under this PA is carried out in accordance with the professional standards and guidelines outlined in the *Secretary of the Interior's Standards and Guidelines for Historic Preservation Projects* and applicable state and tribal authorities.

B) Qualifications. The Corps shall ensure that all work conducted pursuant to this PA is carried out by or under the supervision of persons meeting qualifications set forth in the *Secretary of the Interior's Professional Qualifications Standards*, as amended, for the pertinent discipline (see 48 F.R. 44739). The Corps acknowledges that Affected Tribes possess special knowledge and expertise regarding their tribal values, history, and culture, and properties that may possess traditional religious and cultural significance to them.

22. Annual Report.

The Corps shall prepare a report and distribute it to the Affected Tribes and THPOs, SHPOs, ACHP, and other consulting parties not less than 60 days prior to the date of the annual review. At a minimum, the report shall discuss the topics outlined in Attachment 4 for the past year and the coming year.

23. Semi-Annual Consultation Meetings and PA Annual Review.

A) Semi-Annual Consultation Meetings. The Corps shall host, at a minimum, semi-annual consultation meetings among the affected Tribes, THPOs, SHPOs, ACHP and other consulting parties to discuss the cultural resource program, Annual report, CRMPs and Action Plan status, activity prioritization, budget planning and other budget matters as necessary, PA implementation and the Corps' Section 106 responsibilities, and other topics of concern to the affected Tribes, THPOs, SHPOs, ACHP, and other consulting parties. The Corps, Affected Tribes, THPOs, SHPOs, ACHP, and other consulting parties together shall set the agenda for each meeting by the Corps distributing a call for agenda items at least 30 days prior to the meeting. It is anticipated that one meeting will be during the month of November and the other meeting will be held during the month of April. In order to address new budget issues, a review and planning for the budgetary process shall have priority at the April meeting. The Corps and these parties working together shall develop a schedule for the involvement of the Affected Tribes, THPOs, SHPOs, ACHP, and other consulting parties in the cultural resources activities for the coming year.

B) PA Annual Review. Annually, the Corps, Affected Tribes and THPOs, SHPOs, ACHP, and other consulting parties shall review this PA and progress in carrying out its provisions to determine whether the PA should be amended or terminated. Review of the PA shall occur at one of the semi-annual consultation meetings and be based, in part, on the annual report prepared by the Corps and submitted to parties not less than 60 days prior to the date of the review. Interim review of this PA may occur due to unsatisfactory performance, based on exercise of the dispute resolution clause, by the Corps or signatory party.

24. Funding and Budget Planning.

A) General. The Anti-Deficiency Act, 31 U.S.C. 1341, et seq., applies to this PA and must be followed by the Corps as it accomplishes the tasks that it has agreed to perform in this PA. This means that no action, plan, study, task, or the like shall be construed to require the Corps to obligate or expend funds in excess or in advance of an appropriation authorized by law. In addition, the Federal Acquisition Regulations (FAR) apply to the acquisition of goods and services by the Corps as a result of tasks or actions that must be performed pursuant to this PA.

B) Additional Funding. The Affected Tribes and THPOs, SHPOs, ACHP, and other consulting parties are encouraged to look for other potential funding sources to assist in the implementation of this program. Where applicable, they are encouraged to consider participating in the funding of cultural site preservation through the use of Corps cost sharing programs or other authorities. The Corps agrees that its intent is that all appropriated funds designated for carrying out this PA and attachment 3 will be spent for these purposes. Similarly, the Corps agrees that its intent is that the availability of non-Corps funds for cultural resource purposes will not result in a reduction of Corps appropriated funds for those same purposes.

C) Budget Planning. Annually, the Corps shall provide the Affected Tribes and THPOs, SHPOs, ACHP, and other consulting parties with a 60-day period to review and consult on the Corps' draft list of proposed projects for budget consideration to ensure that they are consistent with the Five-Year Plan and CRMPs and other considerations. Signatory parties may elect to enact a prioritization system.

25. Dispute Resolution.

A) Should a dispute or objection arise regarding any aspect of this agreement or an undertaking subject to review under this agreement, the Corps shall consult with the disputing or objecting party as soon as possible to try to resolve the objection. The disputing or objecting party and the Corps are encouraged to pursue alternative dispute resolution processes including traditional tribal approaches and to consult with the other affected Tribes, THPOs, SHPOs, ACHP and consulting parties.

B) If the disputing or objecting party believes that the consultation has failed to resolve the objection or dispute and wishes to pursue the issue, the party shall notify the Corps in writing within 60 days of the initial notification of the dispute. The Corps shall, within 30 days of the receipt of the disputing party notification, submit all relevant documentation pertaining to the dispute or objection with the Corps written proposal for its resolution to the ACHP with a copy to the disputing party.

C) Within 30 calendar days of receipt of such written submittal, the ACHP shall either:

- i) Notify the Corps that it shall consider the dispute pertinent to the applicable provisions of 36 CFR 800.7 (b) and respond in accordance with that subsection; or
- ii) Provide the Corps with recommendations, which the Corps shall take into account in reaching a final decision; or
- iii) Respond to the Corps that it will not consider the dispute or provide recommendations, in which case the Corps may proceed with the proposed resolution.

D) In the case of a ACHP response of (C)(ii) or (C)(iii), the Corps shall provide a decision to the objecting or disputing party that takes into account the ACHP's response

26. Additional Signatories.

The Corps will consult with the parties to this PA pursuant to stipulation 6 regarding parties who wish to be additional signatories. If the Corps approves the request to become an additional signatory, the party must be a state or Federal governmental agency or an affected tribe or THPO, must sign the Additional Signatory Form in Attachment 5 and submit it to the Omaha District, Army Corps of Engineers. In the annual report or sooner, the Corps shall inform the Affected Tribes, THPOs, SHPOs, ACHP and other consulting parties of additional parties who have signed the PA.

27. Amendments.

The Corps, Affected Tribe, THPO, ACHP, SHPO, or other consulting party to this PA may request that the PA be amended whereupon the parties will consult in accordance with stipulation 6 to consider such amendment(s). Any proposed amendment must be provided to the consulting parties as part of the agenda materials prior to the semi-annual meeting and must be discussed at that meeting. To implement an amendment, consensus among the signatories is required. The amendment must be executed by the signatories and in the same manner as this PA.

28. Withdrawal.

A) Any party to this PA may withdraw from the PA after first providing the other parties written notice that explains the reasons for withdrawal and providing them an opportunity to consult regarding amendment of the PA to prevent withdrawal.

B) In the case of withdrawal from this PA by an Affected Tribe with tribal lands (see definition for tribal lands in Attachment 2) within the scope of this PA or affected by the Corps' undertakings, the Corps shall comply with 36 CFR part 800, subpart B, for all undertakings on or affecting lands within the withdrawing tribe's tribal lands, in lieu of this PA. With respect to historic properties outside of the withdrawing tribe's tribal lands to which that tribe attaches religious and cultural significance, the Corps shall consult with the withdrawing tribe pursuant to 36 CFR part 800, subpart B, in lieu of this PA.

C) Withdrawal from this PA by a SHPO shall require the Corps to comply with 36 CFR part 800 with respect to all undertakings on or affecting lands within that SHPO's area of jurisdiction, in lieu of this PA.

29. Termination.

The Corps, Affected Tribe, THPO, ACHP, and SHPO, or other consulting party who believes that the PA should be terminated shall provide written notification with the reasons for termination to the Corps and other consulting parties at least 60 days prior to a semi-annual consultation meeting. The Corps shall provide this notification in the meeting materials provided to the parties. The parties shall consult to consider an amendment to the PA that would prevent termination. Termination of the PA shall be executed by the consensus of the signatories; or by the ACHP individually; or by a signatory SHPO for its area of jurisdiction; or a signatory Affected Tribe or THPO for its tribal lands within the scope of this PA. In such case, the Corps shall comply with 36 CFR part 800, subpart B, for all undertakings on or affecting lands within the terminating SHPO's area of jurisdiction or the terminating tribe's tribal lands. Termination of this PA in part or entirety will require the Corps to comply with 36 CFR part 800, subpart B with respect to each individual undertaking that would be reviewed under this PA.

30. Duration.

Unless this PA is terminated or amended in accordance with this PA, its duration is 40 years from date of the execution of this PA when it will become null and void.

Execution and implementation of this Programmatic Agreement evidences that the Corps has afforded the ACHP a reasonable opportunity to comment on the effects on historic properties related to the Corps undertakings within the scope of this PA.

AUTHORITY AND TRUST RESPONSIBILITY**AUTHORITY**

The primary purpose and legal authority for this PA are found in the National Historic Preservation Act (16 U.S.C. §470f et seq) (NHPA), particularly section 106 (16 U.S.C. 470f), section 110 (16 U.S.C. 470h-2), and section 101 (16 U.S.C. 470a) of that Act. Federal agency compliance with NHPA section 106 is governed by regulations issued by the Advisory Council on Historic Preservation, 36 C.F.R. part 800, and this PA has been negotiated pursuant to those regulations. The signatories agree that the Missouri River Main Stem System shall be administered in accordance with the stipulations in this PA to take into account and attempt to mitigate adverse effects to historic properties and satisfy the responsibilities of the Corps pursuant to section 106.

In addition to section 106 and the Advisory Council's regulations, numerous other provisions of the NHPA, some of which are cited in the PA, are applicable to activities of the Corps in fulfilling its commitments under this PA. Additionally, the Corps is responsible for complying with other legal authorities, including federal statutes, regulations, executive orders, and guidance documents, as well as any applicable tribal and state laws. Citations to some of these other sources of law are provided here for reference purposes only. In the final section of this attachment, a discussion of the Federal trust responsibilities to Indian Tribes is provided.

9. Cultural Resources Memorandum

November 2002 Message from the Commander, General David Fastabend, Commander of the Northwest Division, in which he discusses Corps responsibilities to Cultural Resources.

10. Trust Responsibility to Indian Tribes

The ACHP recognizes their trust responsibilities to federally recognized Tribes with regard to this PA. The ACHP's trust relationship with Indian Tribes is described in its ACHP Policy Statement Regarding ACHP's Relationship with Indian Tribes, issued November 17, 2000 and updated on April 4, 2003.

** This background information about the federal trust responsibility to Indian Tribes was prepared by tribal attorneys for the educational benefit and convenience of any reader. It was not intended to reflect the views of the U.S. Army, Corps of Engineers and possibly, the consulting parties.*

The Army Corps of Engineers recognizes their trust responsibilities to federally recognized Tribes with regard to this PA.

The trust responsibility is a federal common law and other legal doctrine, the subject of numerous decisions by Federal courts interpreting treaties, statutes, regulation, and executive orders. As described in a 1977 report commission by Congress:

“The purpose of the trust doctrine is and always has been to ensure the survival and welfare of Indian Tribes and people. This includes an obligation to provide for those services required to protect and enhance Indian lands, resources, and self-government, and also includes those economic and social programs which are necessary to raise the

standard of living and social well-being of the Indian people to a level comparable to the non-Indian society.”²

The Federal trust responsibility to Indian Tribes has its roots in land cessions made by Tribes in treaties, in the promises made by the United States to protect the rights of the Tribes to govern themselves in the lands that they had reserved, and in the practice of the federal government holding legal title to most Indian land, subject to Indian rights of occupancy and beneficial use.³ In the present day sense, the trust responsibility can be described as “the federal government’s duty to protect this separatism [of the Tribes] by protecting tribal lands, resources, and the native way of life.”⁴ Congress has explicitly acknowledged that “the United States has a trust responsibility to each tribal government that includes the protection of the sovereignty of each tribal government.”⁵ The trust doctrine includes fiduciary obligations comparable to those of a trustee for the management of trust land and natural resources and funds derived from trust land, including the duty to act “with good faith and utter loyalty to the best interests” of the Indians.⁶ The Federal government has been held liable for mismanagement in some cases.⁷ The Supreme Court has acknowledged “the undisputed existence of a general trust relationship between the United States and the Indian people,”⁸ although for the Federal government to be liable in damages for breach of trust, the Court has held that fiduciary duties must be based on a relevant statute or regulation, or a network of statutes and regulations.

In several lower Federal court decisions, the trust doctrine has been said to extend to Federal agencies other than the agency charged with management of trust land, resources, and funds (i.e., generally the Bureau of Indian Affairs carrying out the authority of the Secretary of the Interior),⁹ Regardless of whether the trust doctrine might

² AMERICAN INDIAN POLICY REVIEW COMMISSION, FINAL REPORT, at 130 (1977) (herein “AIPRC Final Report”), quoted in STEVEN PEVAR, THE RIGHTS OF INDIANS AND TRIBES at 27 (2d ed., 1992).

REV. 1471 (1994) [hereinafter “Wood, Trust I”]; Mary Christina Wood, *Protecting the Attributes of Native Sovereignty: A New Trust Paradigm for Federal Actions Affecting Tribal Lands and Resources*, 1995 UTAH L. REV. 109 (1995) [hereinafter “Wood, Trust II”]. See also FELIX S. COHEN, HANDBOOK OF FEDERAL INDIAN LAW 220-28 (1982 ed.).

⁴ Wood, Trust I, at 1496.

⁵ 25 U.S.C. §3601.

⁶ AIPRC Final Report, *supra* note 1, at 128, quoted in Pevar, *supra* note 1, at 27.

⁷ E.g., *United States v. Mitchell*, 463 U.S. 206 (1983) (liability in money damages for mismanagement of timber resources by the Department of Interior) (often referred to as “Mitchell II” to distinguish this decision from *United States v. Mitchell*, 445 U.S. 535 (1980) (“Mitchell I”), in which the Federal government was not held liable); See also *United States v. White Mountain Apache Tribe*, 537 U.S. 465 (2003) (holding that the Court of Federal Claims has jurisdiction over a breach of trust claim arising out of mismanagement of land and buildings held in trust for tribe but occupied by federal government); *contra* *United States v. Navajo Nation*, 537 U.S. 488 (2003) (holding federal government not liable in damages for alleged breach of trust in leasing of land for mineral extraction).

⁸ *Mitchell II*, 463 U.S. at 225.

⁹ E.g., *Nance v. Environmental Protection Agency*, 645 F.2d 701, 710 (9th Cir. 1981) (EPA held to have a fiduciary duty to consider impacts of Northern Cheyenne Tribe’s designation of its reservation as Class I for air quality purposes on Crow Tribe’s ability to mine coal on its reservation, and finding duty fulfilled); *Pyramid Lake Paiute Tribe of Indians v. U.S. Dep’t of the Navy*, 898 F.2d 1410, 1420 (9th Cir. 1990) (trust obligation to consider impacts on tribal water rights recognized but held to be satisfied through conservation measures); *Morongo Band of Mission Indians v. Federal Aviation Administration*, 161 F.3d 569, 573-74 (9th Cir. 1998) (discussing distinction between general and specific trust responsibility and hold that general responsibility “is discharged through the agency’s compliance with general regulations and statutes not specifically aimed at protecting Indian tribes”); *contra* (*North Slope Borough v. Andrus*, 642 F.2d 589, 611 (1980) (a post-*Mitchell I* and pre-*Mitchell II* decision finding no trust

give rise to judicially enforceable claims, the Tribes expect the Corps to act in accordance with the Federal trust responsibility. This includes government-to-government consultation whenever the Corps' "plans or actions affect trust resources, trust assets, or tribal health and safety."¹⁰

Some Corps actions directly or indirectly affect trust land, and some of the lands managed by the Corps are within reservation boundaries established by treaties where the Tribes and their members continue to have treaty-based rights even though lands have been taken out of trust status. Federal lands managed by the Corps (both within and outside reservation boundaries) include places that hold religious and cultural importance of the Tribes, and some of these places are crucial for the cultural identities of the Tribes and, as such, for the survival of the Tribes as distinct peoples. Some of these places contain the graves of ancestors and funerary objects, in which Federal law recognizes the right of lineal descendants and culturally affiliated Tribes to take custody in the event that they are removed from the Earth. The Tribes expect the Corps to treat these sacred and cultural significant places as subject to the Federal trust responsibility.

This means that they must be engaged in consultation before decisions are made and that the Tribes expect to participate in making decisions and in carrying out decisions. Consultation will be both specific to individual Tribes and with as many comprehensive consultations attended by all affected Tribes, THPOs, SHPOs, ACHP as are necessary with real efforts to reach consensus. Consultations will be conducted in a positive manner, on a government-to-government basis, honoring all treaties and the trust doctrine and other law, which entails a fiduciary and fiscal responsibility of the Corps. Decisions will be made on a government-to-government basis. Finally, the Corps will continue to include, as consulting parties, affected Tribes, THPOs, SHPOs, ACHP in any review or update of the Master Manual.

responsibility in the absence of specific statutory provisions). See Wood, Trust I, *supra* note 2, at 1527-1535, Wood, Trust II at 117-21, *supra* note 2.

¹⁰ The quoted language is from the Department of the Interior's Departmental Manual (DM) and applies to all bureaus and offices within DOI. 516 DM 2.2. While the DM does not apply to the Corps, the Tribes believe that the basic principle does apply to the Corps.

ACRONYMS AND DEFINITIONS

ACRONYMS

ACHP – Advisory Council on Historic Preservation
APE – Area of Potential Effects
ARPA – Archaeological Resources Protection Act
CRMP – Cultural Resources Management Plan
NAGPRA – Native American Graves Protection and Repatriation Act
NHPA- National Historic Preservation Act
SDGFP-South Dakota Department of Game, Fish, and Parks
SHPO – State Historic Preservation Officer
THPO – Tribal Historic Preservation Officer

DEFINITIONS

Adverse Effect – “an effect of an undertaking that may alter, directly or indirectly, any of the characteristics of a historic property that qualify the property for inclusion in the National Register in a manner that would diminish the integrity of the property’s location, design, setting, materials, workmanship, feeling, or association.” 36 C.F.R. §800.5(a). This section of the ACHP regulations provides additional guidance on how to determine whether an effect is adverse and examples of adverse effects.

Advisory Council on Historic Preservation (ACHP) – an independent agency created by the Title II of the National Historic Preservation Act (NHPA), 16 U.S.C. §§470i through 470v. The ACHP issued regulations, 36 C.F.R. part 800, governing the section 106 review process and oversees the conduct of the Section 106 process (see section 106, 16 U.S.C. §470f, and section 211, 16 U.S.C. §470s.)

Affected Tribe – Any Indian Tribe, as defined in this Attachment, that attaches religious and cultural significance to cultural resources, including historic properties, as provided in the scope of this PA, regardless of the location or nature of the undertaking, or regardless of whether the Tribe has been or will be developing any other agreements. Any Tribe that is included in the signatory portion of this PA, whether or not such tribe has signed this PA, and any other Tribe that becomes an “additional signatory” pursuant to Stipulation 26.

Archaeological Resource – “any material remains of past human life or activities which are of archaeological interest,” and that are at least 100 years of age, including graves and human remains if found in an archaeological context, as defined in the Archaeological Resources Protection Act (ARPA), 16 U.S.C. §470bb. The uniform regulations provide extensive elaboration on the definition, including the key phrase “of archaeological interest.” 43 C.F.R. §7.3(a); 32 C.F.R. §229.3(a). The phrase “of archaeological interest” is defined in regulations as “capable of providing scientific or humanistic understandings of past human behavior, cultural adaptation, and related topics through the application of scientific or scholarly techniques such as controlled observations, contextual measurement, controlled collection, analysis, interpretation and explanation.” The statutory definition explicitly includes graves and human remains, which are also the subject matter of the Native American Graves Protection and Repatriation Act (NAGPRA); funerary objects, sacred objects, and objects of cultural patrimony covered

by NAGPRA may be archaeological resources if at least 100 years of age and found in an archaeological context. An archaeological resource may be a historic property, or located within a historic property, as that term is used in the National Historic Preservation Act (NHPA) and this PA. A site at which archaeological resources are located may also be an Indian sacred site as defined in Executive Order 13007.

Area of Potential Effects – “the geographic area or areas within which an undertaking may directly or indirectly cause alternations in the character or use of historic properties, if any such properties exist. The area of potential effects is influenced by the scale and nature of an undertaking and may be different for different kinds of effects caused by the undertaking.” 36 C.F.R. §800.16(d).

ARPA Permitting Process – permit process for the excavation or removal of archaeological resources from federal public lands and Indian lands, established pursuant to ARPA and conducted pursuant to uniform regulations codified at 43 C.F.R. part 7; 32 C.F.R. part 229. For “Indian lands” see also supplemental regulations issued by Department of Interior 43 C.F.R part 7, subpart B (§§7.31 – 37) and supplemental regulations issued by Bureau of Indian Affairs, 25 C.F.R. part 262.

Consensus – For purposes of this PA, consensus means either that all of the signatories agree or that none of the signatories objects.

Consultation – “the process of seeking, discussing, and considering the views of other participants, and, where feasible, seeking agreement with them regarding matters arising in the section 106 process. The Secretary’s ‘Standards and Guidelines for Federal Agency Preservation Programs pursuant to the National Historic Preservation Act’ provide further guidance on consultation.” 36 C.F.R. §800.16(f). The stipulations in this PA provide detail on how consultation will be conducted for purposes of compliance with this PA. Consultation in other contexts may be conducted somewhat differently than as provided for in this PA, and may be subject to the requirements of other statutes, regulations and other sources of law, including those listed in Attachment 2.

Consulting Parties – with the exception of the Corps, all officials and entities named in the “Signatures” section of this PA whether or not they have signed the PA and all additional signatories pursuant to Stipulation 26. Those consulting parties whom are signatories to this agreement shall be consulted and treated as outlined in this PA. Those consulting parties that have not signed will be consulted following the Secretary’s “Standards and Guidelines for Federal Agency Preservation Programs Pursuant to the National Historic Preservation Act” 36 C.F.R. §800.16(f).

Cultural Resource(s) – a general “term of art” without a specific legal definition used to refer to “all elements of the physical and social environment that are thought to have cultural value.” Thomas F. King, *Places That Count: Traditional Cultural Properties in Cultural Resources Management* (Alta Mira Press, 2003), p. 11. For purposes of this PA, cultural resources include historic properties, archaeological resources, sacred sites, religious sites, burial sites, properties of traditional religious and cultural importance, and Native American cultural items (including human remains, associated funerary objects, unassociated funerary objects, sacred objects, and objects of cultural patrimony). A cultural resource site is the location of a cultural resource.

Cultural Resource Management – activities and tasks involved in the stewardship of cultural resources, including to identify, evaluate, maintain, protect, and otherwise treat

cultural resources, and to comply with historic preservation and environmental law (including the NHPA, ARPA, AIRFA, NEPA, EO 13007, EO 13287). These activities and tasks are described in detail in many sources, including federal laws, regulations, and guidance and the “Secretary of the Interior’s Standards and Guidelines for Historic Preservation Projects,” (48 Fed. Reg. 44716) and the many publications of the National Park Service. U.S. Army Corps Engineering Regulation and Pamphlet 1130-2-540 discuss cultural resources stewardship and cultural resources management.

CRMP – cultural resources management plan. See stipulation 9 of the PA.

Effect – “alteration to the characteristics of a historic property qualifying it for inclusion in or eligibility for the National Register.” 36 C.F.R. §800.16(i).

Eligible for Inclusion in the National Register – “includes both properties formally determined to be as such in accordance with regulations of the Secretary of the Interior and all other properties that meet the National Register criteria.” 36 C.F.R. §800.16(l)(2). Criteria of eligibility are codified at 36 C.F.R. §60.6. Regulations of the Secretary of the Interior for determinations of eligibility are codified at 36 C.F.R. part 63. Determinations of eligibility may also be made during the section 106 process. 36 C.F.R. §800.4.

Federal Acquisition Regulations – the regulations governing procurement by federal agencies, codified at 48 C.F.R. Part 1.

Federal Lands – In NAGPRA, the term “Federal lands” is defined as any “lands other than tribal lands which are controlled or owned by the United States, including lands selected by but not yet conveyed to Alaska Native corporations and groups organized pursuant to the Alaska Native Claims Settlement Act.” 25 U.S.C. §3001(5). The substance of this definition closely corresponds to the definition of the term “public lands” as used in ARPA. “Federal lands” that are within the boundaries of an Indian reservation are also “tribal lands” for purposes of NHPA and NAGPRA. [Note: Individual Indian allotments that are outside the boundaries of an Indian reservation and not otherwise within a “dependent Indian community” are considered “federal lands” for purposes of NAGPRA. 60 Fed. Reg. 62140 (1995).]

Final Agency Action – an agency action that is not subject to review within the agency and, as such, may be subject to judicial review in federal court pursuant to the Administrative Procedure Act. 5 U.S.C. §§551, 701 – 706, or other federal statute.

Historic Property – “any prehistoric or historic district, site, building, structure, or object included in, or eligible for inclusion in, the National Register of Historic Places maintained by the Secretary of the Interior. This term includes artifacts, records, and remains that are related to and located within such properties. The term includes properties of traditional religious and cultural importance to an Indian tribe or Native Hawaiian organization and that meet the National Register criteria.” 36 C.F.R. §800.16(l)(1), providing elaboration on the statutory definition codified at 16 U.S.C. §470(w)(5). See also definitions of “eligible for inclusion in the National Register” and “National Register Criteria” in this Attachment.

Historic Resource – is a statutory synonym of “historic property.” 16 U.S.C. §470w(5).

Impacts - any change to a cultural resource site, including a historic property

Indian Land – as defined in the Archaeological Resources Protection Act (ARPA), “lands of Indian Tribes, or Indian individuals, which are either held in trust by the United States or subject to a restriction on alienation imposed by the United States, except for any subsurface interests in lands not owned or controlled by an Indian tribe or an Indian individual.” 16 U.S.C. §470bb(4). This term is not synonymous with “tribal lands” as defined in NHPA and NAGPRA.

Indian Sacred Sites – as used in Executive Order 13007, “any specific, discrete, narrowly delineated location on Federal land that is identified by an Indian tribe, or an Indian individual determined to be an appropriately authoritative representative of an Indian religion, as sacred by virtue of its established religious significance to, or ceremonial use by, an Indian religion, provided that the tribe or appropriately authoritative representative of an Indian religion has informed the agency of the existence of such a site.” Executive Order 13007 (May 24, 1996) (published in notes following 42 U.S.C. §1996). [Note: The definition in EO 13007 is considerably more narrow than the way in which this term is commonly used by Tribes and individual Indians.]

Indian Tribe or Tribe – “an Indian tribe, band, nation, or other organized group or community, including a Native village, Regional corporation or Village Corporation, as those terms are defined in section 3 of the Alaska Native Claims Settlement Act (43 U.S.C. 1602), which is recognized as eligible for the special programs and services provided by the United States to Indians because of their status as Indians.” 16 U.S.C. §470w(4).

Main Stem – the series of dams and reservoirs along the upper Missouri River. For the purposes of this PA those dams and reservoirs are Gavins Point Dam/Lewis and Clark Lake, Fort Randall Dam/Lake Francis Case, Big Bend Dam/Lake Sharpe, Oahe Dam/Lake Oahe, Garrison Dam/Lake Sakakawea, and Fort Peck Dam/Fort Peck Lake.

National Register – the National Register of Historic Places maintained by the National Park Service through the authority of the Secretary of the Interior.

National Register Criteria – the criteria of eligibility for the National Register established in regulations issued by the Secretary of the Interior. 36 C.F.R. §60.6.

Project Lands – land owned by the U.S. Army Corps of Engineers, Omaha District that are associated with the dams and reservoirs on the upper Missouri River. For the purposes of this PA those dams and reservoirs are Gavins Point Dam/Lewis and Clark Lake, Fort Randall Dam/Lake Francis Case, Big Bend Dam/Lake Sharpe, Oahe Dam/Lake Oahe, Garrison Dam/Lake Sakakawea, and Fort Peck Dam/Fort Peck Lake.

Section 106 – section 106 of the National Historic Preservation Act (NHPA), 16 U.S.C. §470f, as implemented through regulations issued by the ACHP, 36 C.F.R. part 800.

Shared Stewardship – pre-decisional consultation with Affected Tribes, THPOs, SHPOs, ACHP and other consulting parties, especially with any Affected Tribe concerning an undertaking that may affect any sacred or cultural resources associated with such a tribe. Any Affected Tribe that attaches religious or cultural importance to a historic resource that is the subject of consultation will have an equal role with the Corps in determining the appropriate treatment and management of the resource.

Signatories – all the parties that have signed this PA, including any that may be added as additional signatories pursuant to stipulation 26.

State Historic Preservation Officer (SHPO) – “the official appointed or designated pursuant to section 101(b)(1) of the [NHPA] to administer the State historic preservation program or a representative designated to act for the State historic preservation officer.” 36 C.F.R. §800.16(v).

Traditional Cultural Property -- a property that is “eligible for inclusion in the National Register because of its association with cultural practices or beliefs of a living community that (a) are rooted in that community’s history, and (b) are important in maintaining the continuing cultural identity of the community.” National Park Service, National Register Bulletin 38, Guidelines for Evaluating and Documenting Traditional Cultural Properties (1990), available at www.cr.nps.gov/nr/publications/bulletins/nrb38/htm.

Treatment Plan – Information describing a historic property and how it is proposed to be treated. Rehabilitation, stabilization (including rripping, revegetation, recontouring of areas surrounding the property, etc.), maintenance, and archaeological excavation are possible treatments.

Tribal Historic Preservation Officer (THPO) – “the tribal official appointed by the tribe’s chief governing authority or designated by a tribal ordinance or preservation program who has assumed the responsibilities of the SHPO [State Historic Preservation Officer] for purposes of section 106 compliance in tribal lands in accordance with section 101(d)(2) of the act.” 36 C.F.R. §800.16(w). [Note: See section 101(d)(2), National Historic Preservation Act, 16 U.S.C. §470a(d)(2).]

Tribal Lands – as defined in the National Historic Preservation Act, “(A) all lands within the exterior boundaries of any Indian reservation; and (B) all dependent Indian communities. 16 U.S.C. §470w(14). Within the scope of this PA, the NHPA definition is identical to the Native American Graves Protection and Repatriation Act (NAGPRA) definition, 25 U.S.C. §3001(15). [Note: “Tribal lands” for purposes of NHPA and NAGPRA is not synonymous with “Indian lands” for purposes of ARPA. Federal lands, including lands administered by the Corps, as well as lands owned by state and local governments and private persons, within reservation boundaries of Indian Tribes are “tribal lands” for purposes of NHPA and NAGPRA. For the purposes of this PA, the service area of the Santee Sioux Tribe of Nebraska shall be considered “tribal lands”.]

Undertaking – “a project, activity, or program funded in whole or in part under the direct or indirect jurisdiction of a Federal agency, including those carried out with Federal financial assistance; those requiring a Federal permit, license or approval...” 36 C.F.R. §800.16(y). [Note: The regulatory definition includes one more clause: “and those subject to State or local regulation administered pursuant to a delegation or approval by a Federal agency.” This clause was the subject of a federal court decision in 2003, and the ACHP has issued a proposed revision to that clause of the regulatory definition. 68 Fed. Reg. 55354 (Sept. 25, 2003).]

The Corps agrees to complete the following with all Affected Tribes: Memoranda of Agreement among the Omaha District, Army Corps of Engineers and Affected Tribes Regarding NAGPRA, ARPA, Paleontological Resources, and Other Items that are Commitments Outside of the Missouri River Main Stem System Programmatic Agreement utilizing but not limited to the following outline:

Should a disagreement occur between the parties that have entered into these requirements the processes under each of these laws shall be used to resolve those disagreements.

Outline:

1. Native American Graves Protection and Repatriation Act (NAGPRA)

a) Inadvertent discoveries of human remains, artifacts, and funerary objects. The Corps will follow the terms of the Native American Graves Protection and Repatriation Act regulations (NAGPRA), 43 CFR 10 et seq and applicable Memoranda of Agreement (MOA) with Tribes.

b) Memorandum of Agreement, North Dakota Intertribal Reinterment Committee. The Corps will follow the provisions as detailed in the North Dakota Intertribal Reinterment Committee (NDIRC) Memorandum of Agreement. This would apply for all those Tribes that have signed the NDIRC MOA. There is a clause in the NDIRC MOA that allows for other Tribes to join the agreement.

c) Memorandum of Agreement, Non-NDIRC Tribes. The Corps will develop a MOA to implement the provisions of the Native American Graves Protection and Repatriation Act (NAGPRA) with those Tribes that have not signed the NDIRC MOA. A draft NAGPRA MOA shall be developed collaboratively with the affected Tribes, THPOs, SHPOs, ACHP, within 2 years of signing of this programmatic agreement. A final NAGPRA MOA shall be completed within 180 days from receipt of comments on the Draft NAGPRA MOA.

d) The Corps will ensure that resources meeting NAGPRA definitions are handled according to the requirements and procedures listed in the NAGPRA regulations or other memoranda of agreement entered into by the Corps and tribal governments. Continued progress will be made on the repatriation of artifacts under the Corps control and protection and located in a museum or curation facility in which the Corps has an active agreement or contractual obligation.

2. Archeological Resources Protection Act.

a) ARPA Permits. Prior to a decision about issuance of an ARPA permit, the Corps will provide copies of the ARPA permit application to affected Tribes, THPOs, SHPOs, ACHP and other consulting parties for review and comment. The Corps will take these comments into account in making a decision about issuance of the permit.

3. Paleontology Resources

a) The Corps will curate paleontology resources in the same manner as archeological collections. Agreements with curation facilities will be formatted according to the example given in 36 CFR Part 79.1.

4. Federal Undertakings and actions on lands outside the scope of this PA

a) In consultation with the Affected Tribes, the Corps, will review its protocols and procedures regarding Corps actions, past and present, beyond the scope of this PA to ensure tribal consultation consistent with Federal laws, Executive Orders, and other legal authorities.

ANNUAL REPORTS

Annually, the Corps shall prepare a report that includes discussion of the following topics both for the past year and as anticipated or planned for the coming year:

- 1) List of all undertakings within the project area;
- 2) Description of all surveys and activities undertaken to identify and evaluate historic properties and results of such efforts;
- 3) Description of all historic properties affected or potentially affected by Corps undertakings;
- 4) Description of measures to avoid, minimize, or mitigate effects to historic properties, including Treatment Plans;
- 5) Status of Five-Year Plan, assessment of progress in meeting its goals, and suggestions for revision;
- 6) Status of CRMPs and assessment of progress in fulfilling recommendations;
- 7) Status of the enforcement program and assessment of its effectiveness;
- 8) Status of site monitoring program and assessment of progress in meeting its goals;
- 9) Status of public education and interpretive activities;
- 10) Status of cultural resources program budget, including funding problems;
- 11) Additional signatories to the PA; notifications to amend, withdraw from, or terminate the PA;
- 12) General assessment of how well the PA is working; and
- 13) Any other facts the Corps considers pertinent to evaluation of the activities covered by the PA and any available information that the affected Tribes, THPOs, SHPOs, ACHP and other consulting parties may have requested that the Corps incorporate into the report.

Introduction and Guide

Introduction

On December 16, 2016, The U.S. Army Corps of Engineers (USACE), Kansas City and Omaha Districts, released the Draft Missouri River Recovery Management Plan and Environmental Impact Statement (MRRMP-EIS) for public review and comment. A Notice of Availability (NOA) of the Draft MRRMP-EIS was published in the *Federal Register* on December 23, 2016. Members of the public also received notice of the availability of the Draft MRRMP-EIS through a news release published following the publication of the NOA in the *Federal Register*.

The release of the Draft MRRMP-EIS initiated a 130-day public comment period that ended on April 24, 2017. This public comment period was announced on the USACE website (<http://moriverrecovery.usace.army.mil/>), posted at 10 libraries located in towns along the Missouri River, and announced through press releases. The Draft MRRMP-EIS was made available through several outlets, including the USACE website, the National Park Service (NPS) Planning, Environment, and Public Comment (PEPC) website at <http://parkplanning.nps.gov/MRRMP>, and on the U.S. Environmental Protection Agency EIS database website. During the comment period, six public meetings, which contained a formal hearing portion, were held in February 2017 throughout the region. These meetings provided the public and opportunity to ask questions, make statements (with a court reporter on hand to record their comments for the official record), and encourage public involvement and community feedback on the Draft MRRMP-EIS. All six of the public meetings were held during the public comment period as follows:

- February 7, 2017: Fort Peck Interpretive Center, Fort Peck, Montana
- February 8, 2017: Bismarck State College-National Energy Center of Excellence, Bismarck, North Dakota
- February 9, 2017: Ramkota Hotel and Conference Center, Pierre, South Dakota
- February 14, 2017: Thompson Alumni Center-Bootstrapper Hall, Omaha, Nebraska
- February 15, 2017: Hilton-Kansas City Airport, Kansas City, Missouri
- February 16, 2017: Double Tree by Hilton Hotel, Chesterfield, Missouri

The public was encouraged to submit comments regarding the Draft MRRMP-EIS online at <http://parkplanning.nps.gov/MRRMP>. The public was also able to submit comments by mailing letters and comment forms to the USACE Omaha District, 1616 Capitol Avenue, Omaha, Nebraska 68102. Public comments from the public meetings were recorded and collected by court reporters. All of the comments received were entered into PEPC in order to organize and analyze each comment.

A total of 244 people signed in at the six public meetings, and a total of 42 people spoke at the public meetings.

During the comment period, 489 pieces of correspondence were received on the Draft MRRMP-EIS and associated background documents (Attachment 2). These background documents included the Draft Science and Adaptive Management Plan (SAMP), 12 human considerations technical reports, and 8 hydrology and hydraulics technical reports. Once all pieces of correspondence were entered into PEPC, each was read, and specific comments within each

piece of correspondence were identified. A total of 1,960 comments were derived from the correspondences received (Attachment 3).

The Comment Analysis Process

Comment analysis is a process used to compile and correlate similar public comments into a format that can be used by decision makers and the Draft MRRMP-EIS planning team. Comment analysis assists the team in organizing, clarifying, and addressing technical information pursuant to National Environmental Policy Act (NEPA) regulations. It also aids in identifying the topics and issues to be evaluated and considered throughout the planning process.

The process includes seven main components:

- Developing a coding structure
- Employing a comment database for comment management (PEPC)
- Migrating all comments in the PEPC website
- Reading and coding of public comments
- Interpreting and analyzing the comments to identify issues and themes
- Drafting concern statements
- Preparing a comment summary

A coding structure was developed to help sort comments into logical groups by topics and issues. The coding structure was derived from an analysis of the range of topics discussed during public scoping, and the comments themselves. The coding structure was designed to capture all comment content and not restrict or exclude any ideas.

The PEPC database was used for management of the comments. The database stores the full text of all correspondence and allows each comment to be coded by topic and issue. Some outputs from the database include tallies of the total number of correspondences and comments received, and sorting and reporting of comments by a particular topic or issue, and demographic information regarding the sources of the comments.

Analysis of the public comments involved assigning codes to statements made by the public in their correspondences. All comments were read and analyzed, including those of a technical nature; opinions, feelings, and preferences of one element or one potential alternative over another; and comments of a personal or philosophical nature.

Although the analysis process attempts to capture the full range of public concerns, this content analysis report should be used with caution. Comments from people who chose to respond do not necessarily represent the sentiments of the entire public. Furthermore, this was not a vote-counting process, and the emphasis was on the content of the comment rather than the number of times a comment was received.

Definition of Terms

Primary terms used in this document are defined below.

Correspondence — A correspondence is the entire document received from a commenter. It can be in the form of a letter, written comment form, transcript, or a comment submitted online using the NPS PEPC website.

Comment — A comment is a portion of the text within a correspondence that addresses a single subject. It could include such information as an expression of support or opposition to the use of a potential management measure, additional data regarding the existing condition, or an opinion debating the adequacy of analysis.

Code — A code is a grouping based on a common subject. The codes were developed during the scoping process and are used to track major subjects throughout the planning process.

Concern Statement — A concern statement summarizes the issues identified in each code. For each code, concern statements were developed to better categorize the content of the comments received. Some codes required multiple concern statements because the comments within them represented different ideas. Other codes had only one concern statement because the comments within them presented similar ideas.

Non-Substantive Comment — Non-substantive comments are those that:

- are in favor of or against the proposed action or alternatives without reasoning that meet the criteria for a substantive comment;
- only agree or disagree with policy or resource decisions without justification or supporting data that meet the criteria for a substantive comment;
- do not pertain to the project area or the project; or
- are vague, open-ended questions.

Substantive Comment — Substantive comments are those that:

- question, with reasonable basis, the accuracy of the information in the NEPA document;
- question, with reasonable basis, the adequacy of the environmental analysis;
- present reasonable alternatives other than those presented in the NEPA document; or
- cause changes or revisions in the proposal.

Guide to this Document

This document is organized as follows.

Content Analysis Report — This section provides information on the numbers and types of comments received, organized by code and by various demographics. The first section is a summary of the number of comments in each code or topic, and the percentage of comments in each code.

Data show the amount of correspondence by type (numbers of park forms, letters, etc.); amount received by organization type (conservation organizations, city governments, individuals, etc.); and amount received by state.

Concern Response Report — This section summarizes the substantive comments received during the public review comment process. These comments are organized by codes and further consolidated into concern statements. USACE provides a response for each concern statement. Correspondence ID and Comment ID numbers are included for each concern statement so the reader can track concern statements and responses back to the related correspondence and comments.

Attachment 1: Index by Organization — This is an index of organizations that provided comments during the comment period. The index includes a list of the correspondence numbers associated with each organization, followed by the codes that were used to categorize comments within the correspondence. Commenters not associated with an organization are shown in the category “Unaffiliated Individual.”

Attachment 2: Correspondence Received on the Draft EIS — This includes the original correspondence received during the comment period.

Attachment 3: Substantive Issues Report — This includes specific comments identified within each piece of correspondence that summarizes the substantive comments received during the comment period. These comments are organized by codes based on a common subject.

Content Analysis Report

Correspondence Distribution by Code – Substantive Comments

Note: Each correspondence has multiple comments and multiple codes. As a result, the total number of correspondence in this table is higher than the actual correspondence totals. Comments made related to an effects analysis for a specific resource were coded under the EIS environmental consequences codes. If the comment was submitted on the EIS and applies to similar information included in the effects analysis and the corresponding technical report for a resource the correspondence was coded under the appropriate EIS code only. If a comment was submitted under a technical report that comment was coded under the appropriate technical report code.

Concern Response Report

BG100 **Background: General Background**

Concern Statement: The Draft MRRMP-EIS should include a statement of the benefits of the dams/reservoirs including to produce hydroelectric power (renewable); mitigate flooding; provide recreation, navigation, and water for multiple human uses (drinking water, cooling water, wastewater treatment, etc.).

Response: Concur, a description of benefits of the Reservoir System and Bank Stabilization and Navigation Project has been added to Section 1.7.

Representative Quotes (Correspondence ID): 107
Comments (Comment ID): 643786

Concern Statement: The Draft MRRMP-EIS presents land acquisition as an Endangered Species Act priority position. USACE's primary obligation on land acquisition is to provide mitigation for the impacts of the Bank Stabilization and Navigation Project.

Response: The primary obligation for land acquisition is to provide mitigation for the impacts of the BSNP; however, the land acquisition authority can be used to support endangered species act focused projects if it is determined the acquisition also supports the purposes of the BSNP mitigation authority. Since the 2003 Biological Opinion, the focus of land acquisition has been to support shallow water habitat (SWH) construction projects which meet the purposes of the BSNP Mitigation Authority and fulfill responsibilities under the ESA. USACE anticipates that land acquisitions within the approximate 15-year timeframe of this plan would continue to prioritize areas that can support the mitigation objectives and ESA objectives.

Representative Quotes (Correspondence ID): 222
Comments (Comment ID): 644792

Concern Statement: The use of "collaboration" or "PrOACT process" or "PrOACT discussions" is not accurate in describing alternative development involving the Missouri River Recovery Implementation Committee (MRRIC).

Response: The acronym PrOACT stands for (1) **P**roblem definition, (2) **O**bjectives, (3) **A**lternatives, (4) **C**onsequences, and (5) **T**radeoffs. MRRIC was engaged in each step of the process. The problem statement was shared with MRRIC and MRRIC's input was included in the final version of the problem statement and included in the EIS. Species objectives were shared with MRRIC and were evaluated by ISAP. ISAP comments and MRRIC feedback were considered and incorporated where appropriate into the final versions of the objectives. Individual MRRIC members or MRRIC as a whole did not design elements of the alternatives such as specific types of habitats, or flow management actions, however, the alternatives were developed by USACE using the results of the effects analysis which was reviewed extensively by ISAP and MRRIC. MRRIC was involved in evaluation of test alternatives and in two rounds of proxy analyses of consequences and tradeoffs. Individual MRRIC members and MRRIC as a committee have had opportunity to provide comment or recommendation regarding the process and its outcome from 2012 to the present. There also will be opportunity for MRRIC to participate in tradeoffs analysis of specific management actions through participation in the adaptive management process as described in Chapters 2 and 5 of the SAMP.

PN8000 *Purpose and Need: Objectives in Taking Action*

Concern Statement: The purpose and need of the MRRMP-EIS only supports three endangered species (piping plover, least tern, and pallid sturgeon) and fails to support or prioritize human needs.

Response: The need for this plan stems from alteration of the Missouri River ecosystem and new knowledge that has been developed about the three endangered species since the 2003 Biological Opinion. The purpose of this plan is to meet ESA responsibilities for the piping plover, least tern, and the pallid sturgeon. USACE developed alternative means of meeting species needs and analyzed the impact of those alternatives on human needs and factored this into identification of a preferred alternative as summarized in Section 2.9 of the Final EIS.

Representative Quotes (Correspondence ID): 89, 222
Comments (Comment ID): 644819, 636795

Concern Statement: The purpose of the plan is to avoid jeopardy, but the plan objectives are recovery-oriented. Recovery is a higher bar than jeopardy avoidance.

Response: Recovery goals are developed by USFWS and provided in Recovery Plans. The Management Plan is designed to support recovery of the species by meeting jeopardy avoidance objectives on the Missouri River. Jeopardy occurs when an action is reasonably expected, directly or indirectly, to reduce appreciably the likelihood of both the survival and recovery of a listed species in the wild by reducing the reproduction, numbers, or distribution of the species. Recovery would be an improvement in the status of listed species to the point at which listing is no longer appropriate under the ESA. USFWS believes that if USACE meets the species objectives then USACE will not appreciably reduce the likelihood of both the survival and recovery of pallid sturgeon, least terns and piping plovers in the wild by reducing the reproduction, numbers, or distribution of the species. The objectives are provided in Section 1.4 of the EIS.

Representative Quotes (Correspondence ID): 96
Comments (Comment ID): 640177

Concern Statement: USACE should broaden the ecological focus of this plan similar to that developed for the Missouri River Ecosystem Restoration process.

Response: USACE has been charged by Congress to meet the authorized purposes of the Missouri River and to meet responsibilities under the Endangered Species Act. USACE has identified a preferred alternative that attempts to identify and correct limiting factors in the ecosystem that are causing jeopardy and that allows USACE to meet the authorized purposes. USACE acknowledges the uncertainties related to pallid sturgeon, least terns, and piping plovers and has developed a comprehensive SAMP designed to incorporate new information about ecosystem limiting factors into future management. Congress has withheld funding for the Missouri River Ecosystem Restoration Plan (MRERP) since 2012 indicating it is not the intent of Congress for the MRERP to move forward at this time.

Representative Quotes (Correspondence ID): 181
Comments (Comment ID): 641461

Concern Statement: The MRRMP-EIS needs to clearly explain how the plover metapopulation influences the two separate populations and how modeling limitations affect persistence probability outputs from the model. Also, USACE should provide the historical relationship of plover populations with acres of emergent sandbar habitat (ESH) if ESH is to operate as a surrogate.

Response: The historical relationship between plover and tern populations and acres of ESH are provided in Section 3.4.1.1 of the Final EIS. The population model assumes that dispersal to and from the Missouri River Mainstem is balanced and thus has no net effect on Missouri River Mainstem plover population dynamics. Little information was available during model development to model dispersal more specifically. As new information from ongoing studies becomes available about dispersal between the southern reaches and the Nebraska tributaries and between the northern reaches and the alkali lakes, the model could be improved to better handle these metapopulation dynamics. At this time, however, the effects of those other populations on Missouri River Mainstem population extinction risks are unknown. This explanation and other known model uncertainties are summarized in the SAMP.

Representative Quotes (Correspondence ID): 107
Comments (Comment ID): 643807

Concern Statement: In order to better meet stated objectives, USACE should implement sufficient management interventions to increase the rate of learning and the pathways to ultimate actions needed, rather than relying on research being complete prior to taking action.

Response: Absent Level 1 or 2 supporting science, there is minimal to no information upon which to design and implement management actions. However, USACE understands that adaptive management must operate under the constraints of the ESA which is why the current SAMP calls for timely Level 3 implementation of plausible management actions, regardless of supporting Level 1 or 2 research and in-river testing in some cases. The framework in the SAMP seeks to optimize tradeoffs between development of knowledge in the near-term to inform implementation decisions and the requirements in the ESA to implement actions based on the best available science. The intent is that the investment in the research activities will result in improved long-term management and improved prospects for meeting objectives. USACE believes that implementation of timely level 3 actions preceded by Level 1 and Level 2 research has a higher likelihood of meeting species objectives than an approach that relies more heavily on trial and error.

Representative Quotes (Correspondence ID): 183
Comments (Comment ID): 643917

Concern Statement: The Purpose and Need statement is too vague and does not provide the public with an honest description of the project goals. Given the importance USACE places on human considerations in its identification of its preferred alternative, it should include a reference to minimizing impacts to human considerations in its purpose and need statement. USACE should also revise its summary of impacts table to clearly show the priority it places on the species compared to human considerations.

Response: USACE believes the purpose and need is an accurate description of the Management Plan objectives. The alternatives are designed to meet the objectives of the plan while taking into account impacts to other resources including “human

considerations.” The reason for analyzing environmental consequences in a NEPA context is so these impacts can be considered in the decision-making process.

USACE used the Purpose, Need, and Objectives to design a reasonable range of alternatives. The purpose of meeting ESA responsibilities does not free USACE from other responsibilities or from considering the impacts of ESA related actions in the decision-making process. USACE has identified a preferred alternative that attempts to identify and correct limiting factors in the ecosystem that are causing jeopardy. USACE selected the alternative that met the species objectives and had the least detrimental impacts across a range of interests. This decision is fully explained in Section 2.9 of the Final EIS along with a full listing of all the interest categories that were considered in the decision-making process.

Representative Quotes (Correspondence ID): 223
Comments (Comment ID): 644941, 645773, 646377

Concern Statement: USACE should prioritize river restoration and modifications to reservoirs to support the recovery of the pallid sturgeon.

Response: As described in Chapter 3 of the EIS, as a whole, the population of pallid sturgeon appears to be stable because of the supplemental stocking by the PSCAP but is not self-sustaining because natural recruitment is apparently not occurring. Stocked pallid sturgeon feed and grow successfully in all Recovery Priority Management Areas (RPMAs) where they have been stocked and have begun to reach sexual maturity in the past few years and spawning is occurring and has been documented. USACE has outlined a scaled approach that ultimately could lead to reservoir and/or flow modification if it is determined these actions would address ecosystem factors limiting pallid sturgeon recruitment. The Effects Analysis and the SAMP present the key uncertainties that challenge implementation decisions for the MRRP. They also detail the rationale and approach to developing the necessary supporting science so that management actions can be implemented and evaluated against expected outcomes with a reasonable expectation that the knowledge gained will contribute to improved understanding, better implementation decisions, and increased likelihood of achieving the program objectives over time. The AM framework provides a measured approach to implementation, recognizing that causal understanding and the development of management-response functions will be necessary to ensure that management actions taken will be effective. This strategy acknowledges the tradeoffs between knowledge and action, emphasizing the need for early investment in understanding so that long-term management prospects are improved.

Representative Quotes (Correspondence ID): 238
Comments (Comment ID): 645321

Concern Statement: The described actions are insufficient to meet the purpose of avoiding jeopardy, especially to the pallid sturgeon (e.g., management of water temperature). Additionally, the Draft EIS failed to use the current state of science on the species.

Response: USFWS has determined the actions are sufficient to avoid jeopardy. USACE and USFWS recognize the results of the Effects Analysis as the best available science on pallid sturgeon. The alternatives development process and subsequent evaluation of impacts to pallid sturgeon was based on the Effects Analysis results. The Draft EIS recognizes the substantial uncertainty that remains relative to cause and effect relationships between management action and pallid sturgeon populations. Adaptive

management was included as a component of all alternatives evaluated in the Draft EIS due to the need to implement actions for pallid sturgeon in a manner that reduces uncertainty regarding pallid sturgeon limiting factors.

Representative Quotes (Correspondence ID): 238, 232
Comments (Comment ID): 645348, 645480

Concern Statement: The problem statement should include language associated with the Flood Control Act of 1944 and the authorized purposes.

Response: The “problem definition” provided in the Draft EIS was a product of the ProACT process with MRRIC and reflected stakeholder concerns about “human considerations” which include continued service to Missouri River authorized purposes. The problem definition is not meant to replace or be a re-wording of the purpose and need statement. The purpose and need statement does not need to make reference to the Flood Control Act of 1944 or other USACE responsibilities for these to be considered in the decision-making process. As documented in Section 2.9, USACE considered impacts to other mission areas and other resources in reaching its decision on a preferred alternative.

Representative Quotes (Correspondence ID): 239
Comments (Comment ID): 645358

Concern Statement: Define the parameters “until sufficient and sustained natural recruitment occurs” in the Final EIS and how those parameters will be measured.

Response: The pallid sturgeon objectives for the MRRMP were developed by USFWS. Pallid Sub-Objective 2 is to: Maintain or increase numbers of pallid sturgeon of age 2 and older until sufficient and sustained natural recruitment occurs. The metric for measuring this sub-objective would be the population estimate for pallid sturgeon for all age classes, particularly for ages 2 to 3 to assess recent trends in recruitment, catch rates of all pallid sturgeon by size class. The target values, by reach, will eventually be informed by the population models being refined as part of the AM process. Possible targets could include: 1) positive population growth rates of pallid sturgeon age 2 and older; 2) estimated survival rates of all size/age classes sufficient to provide a stable population of pallid sturgeon age 2 and older; and 3) acceptable probabilities of persistence and recovery over a 50 to 100-year time frame. At this time, a cause and effect relationship is not known, hence the comprehensive science and adaptive management process designed as part of the Management Plan. The SAMP is designed to increase pallid sturgeon knowledge to the point that a population model can be used to define necessary targets for ultimately meeting the objective.

Representative Quotes (Correspondence ID): 242
Comments (Comment ID): 645526

PN3000 *Purpose and Need: Scope of the Analysis*

Concern Statement: An ecosystem approach for restoration is preferred. The MRRMP-EIS should take a more holistic approach to prevent additional species listing and not focus only on endangered species. Ideally this assessment would fulfill the directive of Section 5018 and evaluate how different levels of restoration of the ecological structure (e.g., riverine/floodplain ecosystem, flow regimes, sediment regimes) can also address and modernize dated aspects of infrastructure and operations associated with the authorized purposes.

Response: Overall ecosystem restoration is outside the scope the Draft EIS. Such a plan would be reflective of the Missouri River Ecosystem Restoration Plan and EIS (MRERP). Congress has withheld funding for MRERP since 2012 indicating it is not the intent of Congress for MRERP to move forward at this time. However, USACE has an obligation under the Endangered Species Act and the MRRP-EIS provides the direction on how USACE will meet those requirements within its need to manage for the authorized purposes.

Representative Quotes (Correspondence ID): 23, 42, 50, 147, 148, 166, 183, 224, 229, 238, 241

Comments (Comment ID): 628476, 640497, 640685, 640711, 642660, 626673, 644870, 644896, 645336, 645340, 645743, 645744

Concern Statement: The MRRMP-EIS should be linked to the Bank Stabilization and Navigation Project (BSNP) Mitigation Project requirements.

Response: As described in Section 1.8.2, the scope of the EIS include actions necessary to comply with the BSNP mitigation plan during the implementation timeframe for this EIS. The need for the Management Plan is based in part on the loss of aquatic and terrestrial habitats due to the BSNP and its contribution to the ESA-listing of the pallid sturgeon, piping plover, and interior least tern.

Representative Quotes (Correspondence ID): 31, 42, 48, 50, 73, 183, 207, 224

Comments (Comment ID): 628477, 628596, 643937

Concern Statement: The purpose and need statement of the Draft MRRMP-EIS does not make its goals sufficiently clear and, as a consequence, does not provide the public with a concise and focused set of objectives for the evaluation of the project alternatives. Human considerations, which are not identified within the purpose and need statement, become controlling factors in the ultimate selection of the preferred alternative that are subordinate to the Endangered Species Act.

Response: USACE considered a full range of reasonable alternatives designed to meet the endangered species objectives and compared the impacts of these different alternatives in terms of resources described in the Affected Environment and Environmental Consequences. Section 2.9 of the Final EIS provides a clear comparison of alternatives in terms of the species objectives, Affected Environment and Environmental Consequences and provides a description of how those factors were weighed in the decision. Sections 3.3 and 3.4 of the EIS provide a more-detailed comparison of the alternatives in terms of species objectives. The environmental consequences section forms the scientific and analytic basis for comparisons of alternatives including the proposed action (CFR 1502.16). NEPA regulations intend decision-makers to use information from the environmental consequences analysis in the decision-making process. That is the purpose of analyzing the environmental impacts of alternatives. Environmental impact resource topics do not need to be designated as objectives or explained as part of the purpose and need in order for them to be considered in decision-making. USACE believes it is appropriate to define the purpose and need statement in terms of the species and to base its decision on a comparison of alternative ways to meet species needs and taking into account the associated environmental consequences.

Representative Quotes (Correspondence ID): 62, 179, 190, 223

Comments (Comment ID): 631174, 645202, 641580, 644941, 645203

Concern Statement: The geographic scope of the MRRMP-EIS should be expanded to include the reach of the Missouri River above Fort Peck Reservoir and the Yellowstone River upstream of Intake Dam. The Draft MRRMP-EIS abandons the three threatened and endangered species populations above Fort Peck and on the Yellowstone River and the Great Plains Management Unit. Under their respective obligations to avoid jeopardy to the species and to ensure instances of "take" are accounted for under the restrictive management and protections of the Endangered Species Act, USACE and USFWS need to evaluate these effects.

Response: Endangered Species Act consultation regulations define the "action area" as all areas to be affected directly or indirectly by the Federal action and not merely the immediate area involved in the action (50 CFR 402.02). The action area defined in the 2017 Biological Assessment was defined as the Missouri River Mainstem and portions of major tributaries including the Kansas and Yellowstone Rivers where listed species could be influenced by USACE operations. USACE Missouri River Mainstem Reservoir operations primarily affect the area of the Missouri River and its reservoir system from the headwaters of Fort Peck Lake in Montana downstream to the mouth of the river near St. Louis MO River Mile 0 at the confluence with the Mississippi River. The action area ends at the confluence of the Missouri and Mississippi River because it was determined that impacts from the proposed action beyond the confluence are not discernable. USFWS found that the BA's described action area is appropriate and found no need to modify it for the 2018 BiOP.

The scope of management actions considered in the MRRMP-EIS was consistent with the scope of the effects analysis. While it is true the full distribution of pallid sturgeon historically included the entire Missouri River and its connection with the Mississippi River, the geographic scope of the effects analysis, including management hypotheses, was constrained in part by the lack of available USACE actions that could influence pallid sturgeon populations upstream of Fort Peck Dam and in part by the present understanding of the geographic distribution of pallid sturgeon. The effects analysis was limited to the Upper Missouri River Mainstem from Fort Peck Dam to the headwaters of Lake Sakakawea, the Yellowstone River upstream from the confluence with the Upper Missouri River for an unspecified distance, the lower Missouri River Mainstem from Gavins Point Dam to the confluence with the Mississippi River at St. Louis, an unspecified distance downstream in the Mississippi River, and various tributaries to these river segments that might be occupied by pallid sturgeon. This scope was developed in coordination with USFWS.

As occurred during the effects analysis (EA), literature and ongoing research from outside the geographic area defined for the effects analysis and MRRP-EIS (e.g., upstream of Fort Peck Dam) may be used where it helps to inform the evaluation of new hypotheses and potential management actions.

Comments (Comment ID): 635353, 643305, 644064, 643304, 644110, 645335, 645337, 645338, 645341, 645343, 645779, 645815

Concern Statement: The geographic scope of the MRRMP-EIS should include the Middle Mississippi River. Potential contributions of larval pallid sturgeon to the Middle Mississippi River suggests that the importance of conservation efforts on the lower Missouri River may be realized in sustaining pallid sturgeon in a greater geographic context. Additionally, to better facilitate the recovery of the listed species, any adaptive management program that includes actions on the lower Missouri River should be

integrated with conservation efforts elsewhere in the system, and supported by a synthetic program of data acquisition and analyses that takes advantage of information derived from studies undertaken beyond the focal area considered in this report.

Response: As occurred during the effects analysis (EA), literature and ongoing research from outside the geographic area defined for the MRRMP-EIS (e.g., upstream of Fort Peck Dam) may be utilized where it helps to inform the evaluation of hypotheses and potential management actions.” This would include information from the Mississippi River. The MRRP Integrated Science Program has already been supporting the microchemistry and genetics studies that are the basis for understanding relations with the Mississippi. Under Big Question 4 on Drift Dynamics, there is a Level 1 field study (component 5) to assess free embryo transport to the Mississippi River. This field study (described in Section C.3.4.5.5 of Appendix C) will estimate the number and survival of age-0 to juveniles hatched in the Missouri that reach the Mississippi River, relative to the number and survival of those that remain in the Missouri River. Additionally, the prospect of extending the Missouri River Pallid Sturgeon Population Assessment Project to include sampling in the Mississippi River (and Platte) is being discussed with partners.

Representative Quotes (Correspondence ID): 107, 139, 168, 222

Comments (Comment ID): 637279, 644833, 645164, 645776

Concern Statement: The MRRMP-EIS should adopt a one-population concept for piping plovers and discontinue jeopardy avoidance operations on the lower Missouri River. In addition, the delisting process should be completed for piping plover.

Response: The approach of evaluating long-term persistence probabilities is conducted in recognition that there are many potential outcomes for dynamic habitat and populations. These outcomes depend on factors that are highly variable and difficult to predict, such as annual weather patterns and long-term climate trends. The historical dynamics of piping plovers depended on many factors including the frequency, timing, and magnitude of ESH-forming flows and drought periods. Future persistence depends, in part, on these factors which may or may not repeat past patterns. The objective of USFWS is to identify an acceptable level of risk. In this case, they have determined that an undesirable outcome of extirpation of plovers on the Missouri River should occur in no more than 1 of 20 potential futures. In some potential futures, plovers may persist without additional management, but USFWS requires that probability to be 95 percent. In addition, changes to the morphology and sediment dynamics of the river may reduce the likelihood that future habitat and population dynamics will reflect the past, particularly the time shortly after dam closure.

Recently collected information about metapopulation processes was not available during the development of alternatives for the Draft EIS. This information will be incorporated to the extent possible in ongoing modeling and evaluation as part of the SAMP.

Representative Quotes (Correspondence ID): 80

Comments (Comment ID): 640103

Concern Statement: Shallow water habitat (SWH), interception and rearing complexes (IRCs), and spawning habitat should all be included under the preferred alternative. Additionally, success for species recovery needs to include designation of critical habitat for the pallid sturgeon and consideration of any tributaries to the Missouri River.

Response: USACE acknowledges the uncertainty related to the IRC, spawning habitat and SWH actions and has defined Channel Reconfiguration to potentially involve several different methods to accommodate habitat creation needs in the future. Some areas that meet velocity and depth criteria for IRCs already exist along the river in non-restored reaches, in reaches that were widened previously to provide SWH, and in side-channel chutes. Some areas along the river that already have sufficient food and foraging habitat may be converted to IRCs by modest changes to a constriction such as a wing-dike structure to create interception hydraulics. Other areas may require construction to provide space to accommodate food and foraging habitats. Alternative 3-6 include the management action of Channel Reconfiguration (Section 2.5.3.1) which consists of the physical manipulation of the river bed or bank to create or improve areas for provision of specific pallid sturgeon habitats thought to be limiting. The suite of actions to create functional habitats under this management action include: Bank notches, Dike notches, Revetment notches and lowering, placement of new structures, off-channel habitat such as chutes and backwaters, and channel widening or top-width widening. It should be noted that the present definitions of food-producing and foraging habitats overlap in part with SWH; however, food producing habitat can be substantially deeper, and foraging habitat can be both deeper and faster. In addition, the IRC concept acknowledges that habitat areas and conditions change substantially with the amount of flow in the river and therefore change over time.

Representative Quotes (Correspondence ID): 131
Comments (Comment ID): 640175

Concern Statement: The MRRMP-EIS should include a significant habitat restoration and management plan targeted at the specific habitat needs of all life stages of the pallid sturgeon (spawning, drift, interception, and rearing). It should also include habitat restoration and management to support the native fish community necessary to support a healthy, reproducing population.

Response: The SAMP includes the creation of IRC habitats and spawning habitat, as well as much associated research to address the habitat needs of life stages of the pallid sturgeon (spawning, drift, interception, and rearing). It will be very important to learn as much as possible during the 9-year period after the ROD. As described in Sections 1.1 and 1.5, the scope of the EIS includes actions consistent with the BSNP mitigation plan during the implementation timeframe for this EIS which could include restoration and management to support the native fish community.

Representative Quotes (Correspondence ID): 237
Comments (Comment ID): 642897

Concern Statement: The MRRMP-EIS should focus efforts and available budget resources on habitat restoration for any chance of success under the highly modified system of the Missouri River.

Response: The alternatives presented in the EIS include habitat restoration components for the three listed species. However, the creation of habitat alone will not reduce other disturbances, limiting factors, or stressors as identified in the effect analysis. The effects analysis process resulting the development of conceptual ecological models that served to help identify management hypotheses and ultimately alternatives. Management alternatives were designed to improve species conditions and mitigate or eliminate the effects of stressors that may limit species reproduction and survival. Focusing on habitat alone would not address other stressors like increased predation that could impact

species survival. Therefore, the alternatives considered other actions beyond habitat restoration.

Representative Quotes (Correspondence ID): 207
Comments (Comment ID): 643521, 643522

Concern Statement: USACE should increase the level of implementation (magnitude and scope) of management actions to improve and expedite the adaptive management process and to help ensure the purpose and objectives of the Draft MRRMP-EIS are achieved.

Response: USACE believes that it has established management actions at a sufficient magnitude to see resource response. The SAMP is designed to incorporate information from monitoring species response including increasing the level of implementation if necessary.

Representative Quotes (Correspondence ID): 183
Comments (Comment ID): 643917

Concern Statement: Additional habitat for piping plover and least terns (alkaline lakes, sand mines, ash pits, out of channel sand deposits, islands in oxbows, large point bars) should be included as management actions in the preferred alternative.

Response: USACE considered "Off-Channel" habitat creation and purchase on Missouri River segments as part of alternatives development. This management action was eliminated from further consideration because it is not currently demonstrated to be as effective or efficient at meeting species objectives relative to other available management actions such as in-river construction of ESH and vegetation management on ESH. Although this action was eliminated from consideration in the EIS, USFWS has expressed a willingness to pursue funding for a pilot project. This funding would not be through the USACE MRRP; however, the results of any pilot project could be evaluated under the SAMP. As stated in the SAMP, long-term changes off-river affecting Missouri River populations may require adjustments to target criteria or objectives. The AM process would incorporate the results of future metapopulation modeling as it becomes available in order to improve management decisions.

Representative Quotes (Correspondence ID): 107, 239
Comments (Comment ID): 643918, 645360

Concern Statement: The MRRMP-EIS should consider actions in the reach below Fort Peck Dam for flow and temperature modifications; addressing hydropeaking from Fort Peck and Fort Randall Dams to increase recruitment of pallid sturgeon; increase floodplain connectivity to allow for nutrient and sediment inputs; and implement top-width widening. "Take" of pallid sturgeon will continue in the Missouri River between Fort Peck Dam and Lake Sakakawea due to the effects of unnatural flows and temperatures on pallid sturgeon and their habitats caused by the hypolimnetic discharge from Fort Peck Dam.

Response: Modifications at Fort Peck Dam were considered during alternatives formulation. Please see Section 2.5.21 of the Final EIS for a detailed discussion of the status of actions at Fort Peck Dam. In recognition of the scientific uncertainty surrounding Fort Peck flow adjustments, USACE agreed to formulate test flows from Fort Peck and an AM framework for their implementation during formal ESA Section 7 consultation on this plan. Studies under the framework may include additional drift studies, tracking of fish and documentation of spawning locations, telemetry evaluations and methodology

improvements, risk analysis, and engineering studies. Implementation of an identified hydrograph to test hypotheses would be considered; however, depending on the specifics of the test hydrograph, may be outside the scope of this EIS.

Representative Quotes (Correspondence ID): 183, 191

Comments (Comment ID): 643933, 644088, 644100

Concern Statement: The MRRMP-EIS and its associated adaptive management plan should include the reach between Gavins Point Dam and Fort Randall Dam within the geographic scope. Despite effects of the operations of the Mainstem dams, portions of this reach still provide the type of natural habitat complexity that are highly altered or absent elsewhere in the basin.

Response: The reservoirs and inter-reservoir reaches (from Lake Sakakawea to Lewis and Clark Lake) are excluded from the effects analysis based on the assumption that these habitats are unlikely to support reproductive populations of pallid sturgeon. These assumptions may be revisited if conflicting information arise through the science and adaptive management process.

Representative Quotes (Correspondence ID): 183

Comments (Comment ID): 643941

Concern Statement: The full geographic range of jeopardizing conditions for all three species should be included and studied as part of a comprehensive, scientific evaluation; not just the downstream effects. The geographic scope should also include the full range of the endemic species. The purpose and need statements do not reflect the full geographic range where USACE has both authority and current management actions.

Response: Endangered Species Act consultation regulations define the “action area” as all areas to be affected directly or indirectly by the Federal action and not merely the immediate area involved in the action (50 CFR 402.02). The action area defined in the 2017 Biological Assessment was defined as the Missouri River Mainstem and portions of major tributaries including the Kansas and Yellowstone Rivers where listed species could be influenced by USACE operations. USACE Missouri River Mainstem Reservoir operations primarily affect the area of the Missouri River and its reservoir system from the headwaters of Fort Peck Lake in Montana downstream to the mouth of the river near St. Louis MO River Mile 0 at the confluence with the Mississippi River. The action area ends at the confluence of the Missouri and Mississippi River because it was determined that impacts from the proposed action beyond the confluence are not discernable. USFWS found that the BA’s described action area is appropriate and found no need to modify it for the 2018 BiOP.

The scope of management actions considered in the MRRMP-EIS was consistent with the scope of the effects analysis. While it is true the full distribution of pallid sturgeon historically included the entire Missouri River and its connection with the Mississippi River, the geographic scope of the effects analysis, including management hypotheses, was constrained in part by the lack of available USACE actions that could influence pallid sturgeon populations upstream of Fort Peck Dam and in part by the present understanding of the geographic distribution of pallid sturgeon. The effects analysis was limited to the Upper Missouri River Mainstem from Fort Peck Dam to the headwaters of Lake Sakakawea, the Yellowstone River upstream from the confluence with the Upper Missouri River for an unspecified distance, the lower Missouri River Mainstem from Gavins Point Dam to the confluence with the Mississippi River at St. Louis, an

unspecified distance downstream in the Mississippi River, and various tributaries to these river segments that might be occupied by pallid sturgeon. This scope was developed in coordination with USFWS.

USACE recognizes that some species life-cycles, especially least tern and piping plover occur outside of the study area. However, the aspect of the life-cycle affected by USACE river operations is breeding and nesting and the focus of this planning effort. However, understanding the actions that USACE will be taking to improve species survival and reproduction, USFWS can consider these benefits when consulting with entities in other portions of the species range.

As occurred during the effects analysis (EA), literature and ongoing research from outside the geographic area defined for the MRRP-EIS (e.g., upstream of Fort Peck Dam) may be used where it helps to inform the evaluation of hypotheses and potential management actions.

Representative Quotes (Correspondence ID): 166
Comments (Comment ID): 644834, 644835

Concern Statement: If any of the reserve hypothesis turn out to be the critical, scientific issues that might have been considered during a time-critical window could create new and different kinds of jeopardy for the three species.

Response: Through the effects analysis and the development of the SAMP, USACE identified a number of reserve hypotheses. These include hypotheses that are not deemed important to investigate at this time, have high uncertainty and require further investigation, or are outside of USACE authority. If new information arises or additional authorities are granted that suggested re-evaluation of a reserve hypotheses, USACE will determine whether to move forward with the hypotheses and conduct the appropriate level of NEPA review prior to implementation.

Representative Quotes (Correspondence ID): 166
Comments (Comment ID): 644839

Concern Statement: The purpose and need statements should reflect whether budgetary appropriations and expenditures are influencing factors in the MRRMP-EIS. Additional alternative financing sections could be added to the MRRMP-EIS.

Response: Cost was not considered in development of the alternatives. Additionally, no alternative was rejected solely because of cost reasons although costs of the various alternatives were developed for comparison between alternatives. The alternatives were designed to meet species objectives and the impacts of the different alternatives were estimated and compared.

Representative Quotes (Correspondence ID): 166
Comments (Comment ID): 644888

Concern Statement: The Purpose and Need Statement fails to provide guiding criteria for USACE to meet its obligations under the Endangered Species Act. Due to the vagueness of the purpose and need statement, the MRRMP-EIS uses criteria for the selection of an alternative that have little to do with accomplishing species objectives, and much to do with ensuring that the selected alternative maximizes human consideration interests. To remedy this inadequacy, the MRRMP-EIS should reformulate its purpose and need statement to efficiently identify the agency's responsibilities and produce an EIS which properly focuses on species objectives and goals.

Response: USACE considered a full range of reasonable alternatives designed to meet the endangered species objectives and compared the impacts of these different alternatives in terms of resources described in the Affected Environment and Environmental Consequences. Section 2.9 of the Final EIS provides a clear comparison of alternatives in terms of the species objectives, Affected Environment and Environmental Consequences and provides a description of how those factors were weighed in the decision. More-detailed comparisons of the alternatives in terms of species objectives are provided in Sections 3.3 and 3.4. The environmental consequences section forms the scientific and analytic basis for comparisons of alternatives including the proposed action (CFR 1502.16). NEPA regulations intend decision-makers to use information from the environmental consequences analysis in the decision-making process. That is the purpose of analyzing the environmental impacts of alternatives. Environmental impact resource topics do not need to be designated as objectives or explained as part of the purpose and need in order for them to be considered in decision-making. It is appropriate to define the purpose and need statement in terms of the species and to base its decision on a comparison of alternative ways to meet species needs and the associated environmental consequences.

Representative Quotes (Correspondence ID): 223
Comments (Comment ID): 644936, 644939

Concern Statement: The MRRMP-EIS should include modifications to increase the emphasis on development of pallid sturgeon science, include sediment management as a component of the management plan, and actively address flow constraints from Fort Randall Dam to Lewis and Clark Lake.

Response: The SAMP outlines a comprehensive and structured approach for conducting pallid sturgeon science and incorporating the results into future management. As described in Section 2.10, USACE will continue to analyze how the flow release under the preferred alternative may impact private landowners and if these impacts are covered by any existing easements. Where an easement does not already exist, USACE will continue to effectively strategize how to minimize the impacts over the next nine years. Sediment transport issues are the subject of the Lewis and Clark sediment management study funded by the MRRP (available at <https://linkprotect.cudasvc.com/url?a=https://www.moriverrecovery.org&c=E,1,5GkqO45bb8CllqKfL5i0v5MQomxeCPRVnp1QCyd5hnVMi0jZaB5nyt4rgB7UYvbtVGpCjFQJISjn7uyKCSJq8q6snvffFm65fDdlvRsCRGRWjzbhxm&typo=1>). Phase II of this study is ongoing. In the future, it is likely that MRRP will continue to fund sediment management studies where sediment issues intersect with ESA issues.

Representative Quotes (Correspondence ID): 206
Comments (Comment ID): 645153

Concern Statement: The MRRMP-EIS should develop a more specific Purpose and Need Statement and reduce prioritizing the human consideration impacts.

Response: The purpose and need along with the species objectives provide enough specificity to allow comparison of alternatives, and ultimately, to determine if the selected alternative is successful. USACE has examined the impacts on human considerations and other resources in the Affected Environment and Environmental Consequences, but has not prioritized them. USACE has identified an alternative that meets the purpose and need and species objectives that has the least amount of impact to the range of interests identified in the Affected Environment and Environmental Consequences

sections. The reasoning behind the decision has been provided in Section 2.9 of the Final EIS.

Representative Quotes (Correspondence ID): 179
Comments (Comment ID): 645200

Concern Statement: Land acquisition programs should include sale-leaseback to enable portions of prime farmland kept productive while conservation plans are devised and implemented.

Response: Current practice is to allow a portion of lands purchased for BSNP Mitigation to be available for farming leases. It is anticipated that this practice would continue under the plan.

Representative Quotes (Correspondence ID): 221
Comments (Comment ID): 645299

Concern Statement: Key tributaries, like the Platte River, should be included within the geographic scope of the MRRMP-EIS.

Response: The effects analysis included various tributaries to the Upper Missouri River Mainstem from Fort Peck Dam to the headwaters of Lake Sakakawea, the Yellowstone River upstream from the confluence with the Upper Missouri River for an unspecified distance, the lower Missouri River Mainstem from Gavins Point Dam to the confluence with the Mississippi River at St. Louis, and unspecified distance downstream in the Mississippi River that might be occupied by the pallid sturgeon. USACE considered the Platte River Flow Management hypothesis and given the high degree of uncertainty and availability of other management actions did not consider this a reasonable hypothesis to include in developing alternatives under the Management Plan. However, the geographic scope of the MRRP, as defined in Chapter 4 of the SAMP does not preclude efforts by USACE to coordinate with other entities involved in developing actions on tributaries. Additionally, the effects from the Platte River Recovery Implementation Program were considered as part of the cumulative impacts, including the three listed species, as the program is seeking to enhance, restore, and protect habitat for those species.

Representative Quotes (Correspondence ID): 242
Comments (Comment ID): 645540

Concern Statement: The MRRMP-EIS should describe within the SAMP what actions would be taken and when and what actions would not be implemented within the timeframe identified.

Response: Chapter 4 of the MRRP-EIS describes the implementation of the preferred alternative under adaptive management. This chapter summarizes how USACE would implement the preferred alternative under the SAMP recognizing the remaining uncertainty associated with many of the proposed management actions and with the ecology of the listed species (particularly for the pallid sturgeon). A proposed schedule for implementation can be found in Figures 4-4 and 4-5.

Representative Quotes (Correspondence ID): 184, 238
Comments (Comment ID): 645789, 645835

Concern Statement: The Final MRRMP should include additional mitigation lands, particularly in Missouri, and this should be described/documented in the Final EIS.

Response: As described in Sections 1.1 and 1.5, the scope of the EIS include actions necessary to comply with the BSNP mitigation plan during the implementation timeframe for this EIS. The BSNP mitigation program will continue during the implementation of the MRRMP. In fact, the need for the EIS is based in part on the loss of aquatic and terrestrial habitats due to the BSNP and its contribution to the ESA-listing of the pallid sturgeon, piping plover, and interior least tern.

Representative Quotes (Correspondence ID): 177
Comments (Comment ID): 644597

ON1000 Other NEPA Issues: General Comments

Concern Statement: The Draft EIS document should be subject to independent science review.

Response: There is no requirement under NEPA to subject draft environmental impact statements to independent scientific reviews. However, as part of the USACE process, the EIS has been through an agency technical review and an independent external peer review. These reviews exceed the required 45-day public review of a draft EIS.

Representative Quotes (Correspondence ID): 9, 23, 77
Comments (Comment ID): 626671, 636785

Concern Statement: USACE needs to visit reservations to discuss the Draft EIS because the Tribes do not have money to travel.

Response: USACE has had a number of meetings with potentially impacted Tribes and travelled to meet with Tribal leaders on Tribal reservations multiple times during preparation of the EIS. See Chapter 5 for a discussion of Tribal coordination and consultation.

Representative Quotes (Correspondence ID): 9
Comments (Comment ID): 627490

Concern Statement: The lower Missouri River basin acreage requirement is deficient and the Draft EIS should discuss this issue.

Response: The 2003 Supplemental EIS for the BSNP Mitigation Program does not specify an end date at which all mitigation acreage needs to be acquired and clearly states that the BSNP mitigation program implementation would be subject to funding constraints.

Representative Quotes (Correspondence ID): 42
Comments (Comment ID): 628482

Concern Statement: The public should have been allowed to ask questions in front of all who attended the hearing at the Draft EIS public meeting.

Response: The purpose of the public meetings was to allow the agency to collect comments on the Draft EIS in order to understand the concerns of the public and make any appropriate changes to the EIS. There are a variety of formats that can be used from open house formats to public hearing formats. Each has benefits allowing the public to engage with agency staff in different ways. Oftentimes during more formal hearing portions of meetings, the agency must limit the amount of time to each speaker to

ensure that anyone who wants to speak is able to within the time allotted for the meeting. However, speakers are and were encouraged to submit their entire comment if they were unable to convey it all verbally within the allotted time.

Representative Quotes (Correspondence ID): 90
Comments (Comment ID): 636828

Concern Statement: Any decision made outside the Record of Decision (ROD) must go through full NEPA review and a separate environmental impact statement. Rigorous review should also apply to any adaptive management decision that goes beyond the scope of the Master Manual.

Response: As described in Section 4.9, decisions or actions not contemplated in the EIS could require additional NEPA analyses. This could come in the form of an environmental assessment or environmental impact statement. However, USACE could also streamline the analysis using a tiered NEPA document or issuing a supplemental Final EIS depending on the type of action and relationship to the existing EIS.

Representative Quotes (Correspondence ID): 27, 64, 98, 145, 173, 176, 228, 229
Comments (Comment ID): 637641, 641391, 633688, 633523, 644765, 644897, 645468, 645625, 645910

Concern Statement: USACE should include information on the number and character of acres of land offered for sale under the BSNP mitigation or other programs in the Missouri River basin.

Response: Landowners place land on the market and remove land from the market on a regular basis so there is not a set number of land available for purchase. Landowners sometimes approach USACE willing to sell and USACE sometimes asks specific landowners if they would be willing to sell if a property is needed for a project. Providing the number and character of acres offered for sale at a snap-shot in time does not appear to be a pertinent metric for the MRRMP-EIS.

Representative Quotes (Correspondence ID): 131
Comments (Comment ID): 640155

Concern Statement: Adequate time was not allocated to the process of selecting alternatives, thus limiting the number of alternatives in the Draft EIS.

Response: The Notice of Intent to prepare the Draft EIS was issued on August 9, 2013. USACE then developed the Draft EIS over a three-year period and released it in December 2016. The agency feels that is was an adequate amount of time to develop a range of alternatives to be analyzed in the EIS. No alternatives were selected at the time of the Draft EIS for implementation, but rather USACE identified their preferred alternative. USACE will not select an alternative until a Record of Decision is issued.

Representative Quotes (Correspondence ID): 192, 205
Comments (Comment ID): 642125

Concern Statement: The SAMP is an integral component of the MRRMP and should be recognized and its acceptance documented by the ROD. The ROD should also acknowledge the living nature of the SAMP.

Response: USACE agrees with the commenter and plans to include adoption of the SAMP as an integrated part of the Record of Decision.

Representative Quotes (Correspondence ID): 148, 229
Comments (Comment ID): 642690, 644898

Concern Statement: There should be an opportunity to review any future changes to the proposed Missouri River system operations that would result from implementation of the new system of adaptive management process.

Response: Any changes to the operations of the Missouri River system will likely require a separate NEPA process and associate opportunity for the public to review and comment on any proposed changes.

Representative Quotes (Correspondence ID): 167
Comments (Comment ID): 643878

Concern Statement: USACE should establish a process within the SAMP for identifying new management actions and their status with regard to existing NEPA coverage early in the study process (e.g., Level 1). Early NEPA compliance documentation would allow rapid implementation of new approaches at Levels 2 and 3.

Response: Section 4.9 describes how USACE will determine the additional need for future NEPA analyses based on the development of adaptive management actions considered for implementation.

Representative Quotes (Correspondence ID): 184
Comments (Comment ID): 643965

Concern Statement: More design options are needed for habitat discussion within MRRIC regarding fish and wildlife habitat and human interests.

Response: Specific design options are examined on a site-specific basis. The MRRMP-EIS is a programmatic document that describes the general types of construction actions that could occur as part of the preferred alternative. Continuing engagement with MRRIC and site-specific NEPA processes will allow input on detailed site-specific designs.

Representative Quotes (Correspondence ID): 225
Comments (Comment ID): 644421

Concern Statement: MRRIC members were not appropriately treated in making meeting materials available for MRRIC meetings; and insufficient time was provided for review of the Draft EIS.

Response: In response to concerns about insufficient time to review the Draft EIS and associated documents, USACE extended the original 60-day comment period. The revised comment period extended from Dec. 26, 2016, through April 24, 2017 or roughly 120 days.

Representative Quotes (Correspondence ID): 225
Comments (Comment ID): 644423

Concern Statement: The review team that conducts the comprehensive Independent Peer Review of a USACE Draft EIS must include individuals who have a comprehensive understanding of the navigation economic model.

Response: USACE believes ISAP and ISETR have the necessary expertise as evidenced by extensive comments on the navigation analysis provided in their IEPR review of the Draft EIS and Draft SAMP.

Representative Quotes (Correspondence ID): 176
Comments (Comment ID): 644759

Concern Statement: To assume at this stage in the NEPA process that flood pulse alternatives would not be selected is an error that preordains the outcome and shorts the NEPA process.

Response: In the Draft EIS, USACE did not select an alternative as alternatives are only selected in a Record of Decision, and the selection of an alternative in a Draft EIS would be pre-decisional. Rather, USACE identified a preferred alternative to allow the public to understand which alternative USACE would prefer to implement at that time.

Representative Quotes (Correspondence ID): 166
Comments (Comment ID): 644877

Concern Statement: USACE is encouraged to incorporate into the purpose and need statement the primary goals for species restoration and a brief description of the various measures that can accomplish those goals.

Response: As defined by 40 CFR § 1502.13, the purpose and need section of a NEPA document is a discussion of the underlying purpose and need to which the agency is responding in proposing the alternatives. However, the Draft EIS exceeds this requirement by providing a discussion of plan objectives, which are how USACE will measure whether alternatives would meet the purpose and fulfill the need of the plan.

Representative Quotes (Correspondence ID): 223
Comments (Comment ID): 644935

Concern Statement: Any of the Draft EIS alternatives that would require a change in the Master Manual cannot be considered without a separate NEPA process.

Response: Any changes to the operations of the Missouri River system will likely require a separate NEPA process and associated opportunity for the public to review and comment on any proposed changes

Representative Quotes (Correspondence ID): 168
Comments (Comment ID): 645126

Concern Statement: USACE does not have organic or independent authority to proceed on flow changes without Congressional authorization and utilization of the NEPA process.

Response: Any changes to the operations of the Missouri River system will likely require a separate NEPA process and associated opportunity for the public to review and comment on any proposed changes. However, the EIS considers actions currently outside of the Master Manual to ensure all reasonable alternatives were considered.

Representative Quotes (Correspondence ID): 168
Comments (Comment ID): 645184

Concern Statement: The Draft EIS admits "a supplemental NEPA process may be necessary prior to the end of the 15-year period." Yet, it fails to clarify the kind of action which would trigger this requirement, such as going beyond the dictates of the Master Manual.

Response: NEPA regulations provide clear guidance on when to prepare a supplemental EIS. 40 CFR § 1502.9 states that Agencies "shall prepare supplements to either draft or Final environmental impact statements if: (i) The agency makes substantial changes in the

proposed action that are relevant to environmental concerns; or (ii) There are significant new circumstances or information relevant to environmental concerns and bearing on the proposed action or its impacts.” USACE intends to follow these regulations in determining whether supplemental NEPA processes are necessary.

Representative Quotes (Correspondence ID): 168
Comments (Comment ID): 645186

Concern Statement: The Draft EIS is presently a perfect example of permitting substantial changes without fully satisfying NEPA requirements.

Response: Although it is somewhat unclear as to the commenter’s assertion, it is assumed for purposes of response that they are referring to the consideration of alternatives that would require changes to the Master Manual. However, USACE did not select an alternative for implementation at the time the Draft EIS was released. Rather, USACE merely identified a preferred alternative. If USACE were to ultimately seek to implement an alternative outside of the Final EIS and Record of Decision, USACE would initiate a new NEPA process.

Representative Quotes (Correspondence ID): 168
Comments (Comment ID): 645187

Concern Statement: The Fischenich et al. (2014) report is a crucial document underpinning the geomorphic analysis of the Draft EIS. This report was not made available to the public along with the other Effects Analysis reports that were released with the MRRMP-EIS. It was only disclosed (in an incomplete version) after February 16, which was halfway through the 120-day comment period. This compromised our ability to conduct a full and rigorous review of the material.

Response: NEPA does not require that an agency publish all references used to develop the NEPA document. Instead the EIS included a reference chapter to allow reviewers to better understand the documents upon which the agency relied. USACE exceeded the publication requirements by making the effects analysis reports available for reference during the public comment period.

Representative Quotes (Correspondence ID): 239
Comments (Comment ID): 645363

Concern Statement: When will the referenced SAMP text (page 105) under development be available for public review?

Response: The SAMP was released as a companion document with the Draft EIS and was available for review during the same period.

Representative Quotes (Correspondence ID): 242
Comments (Comment ID): 645598

Concern Statement: How can the public comment on material contained in Section 2.6.3, Data and Information Management, when the referenced dates have already passed at the time the comment period on the Draft MRRMP-EIS had ended?

Response: Comment Noted. Chapter 4 of the EIS and Chapter 6 of the SAMP provide a thorough description of the Data and Information Management structure. These descriptions were in the Draft EIS and are in the Final EIS.

Representative Quotes (Correspondence ID): 242
Comments (Comment ID): 645606

Concern Statement: The lack of oversight for administrative decisions in the SAMP permits USACE to take actions not presently authorized by the Record of Decision (ROD) without first satisfying additional NEPA requirements.

Response: USACE will assess the environmental review requirements of any new actions proposed as part of the SAMP as described in Section 4.9 of the Draft EIS.

Representative Quotes (Correspondence ID): 228
Comments (Comment ID): 645626

Concern Statement: The Draft EIS and the SAMP open the door to actions that go beyond the established ROD without automatically triggering a full NEPA process to produce a supplemental EIS, as is required by law. The Draft EIS fails to clarify what constitutes warranted and feasible options.

Response: USACE will assess the environmental review requirements of any new actions proposed as part of the SAMP as described in Section 4.9 of the Draft EIS.

Representative Quotes (Correspondence ID): 228
Comments (Comment ID): 645627

Concern Statement: The Draft EIS should specify a robust process for ongoing analysis of economic impacts of SAMP actions to be able to inform the process and decisions regarding changes to management plan actions, while ensuring compliance with the Master Manual.

Response: Comment Noted. Chapter 5 of the EIS provides a thorough description of the approach that will be followed related to ongoing analysis of economic impacts.

Representative Quotes (Correspondence ID): 228
Comments (Comment ID): 645640

Concern Statement: In the Final EIS, USACE should consider major droughts for post-event investigations.

Response: Comment noted. Post-drought investigations related to species response would be covered by the ongoing monitoring programs for pallid sturgeon and terns and plovers which occur every year.

Representative Quotes (Correspondence ID): 242
Comments (Comment ID): 645801

Concern Statement: USACE, in concert with the State, must develop guidance on how mitigation in the connected Missouri River Yellowstone River ecosystem will avoid jeopardy to pallid sturgeon as well as mitigate for impacts to other native fish and wildlife species. This should be included in the alternative analysis prior to its finalization of the EIS.

Response: Mitigating for impacts to fish and wildlife species beyond the three ESA listed species is beyond the scope of this Plan although it is likely that actions taken for endangered species would have incidental benefits to other native fish and wildlife species as described in Chapter 3 of the EIS.

Representative Quotes (Correspondence ID): 236
Comments (Comment ID): 646302

Concern Statement: What is the weight given to the filtering for human considerations as depicted in Figure 4 on page 11? How much negative impact causes a management action to be eliminated? How is the negative impact quantified? How large a part does the socioeconomic have in evaluating the actions – what percent among the other criteria? Nothing is said in Figure 4 of the level of filtering that occurs. Human Considerations was barely mentioned in the Executive Summary, yet considerable weight was given to them in the alternative analyses. This should be clearly laid out for the public to know if any particular human consideration / interest group received greater weight than others.

Response: A quantified weighting of different resource categories was not conducted nor is this required by NEPA. The EIS clearly describes the reasons for selection of the preferred alternative in Section 2.9 of the EIS. The environmental consequences section forms the scientific and analytic basis for comparisons of alternatives including the proposed action (CFR 1502.16). NEPA regulations intend for decision-makers to use information from the environmental consequences analysis in the decision-making process.

Comments (Comment ID): 645238

PN10000 Purpose and Need: Compliance with Other Laws, Policies, and Regulations

Concern Statement: The SAMP lacks any assurances that the laws of North Dakota will be supported or that the state will be part of the decision-making process. The lack of a clearly defined collaborative process requiring state agreement prior to implementing a level 2, 3, or 4 action raises concern/suspicion that state laws will not be respected. The SAMP lacks identified limits of hydraulic modification that could occur and the lack of a clear process to consult the state being affected by the decision-making process in implementing the SAMP. In order to be acceptable, the SAMP needs a science supported menu of actions with or without a limited amount of substitutions to ensure maintenance of existing beneficial uses and protection of aquatic life. North Dakota cannot support Alternative 3 without inclusion of specific boundaries in the SAMP that would protect existing beneficial uses and support state water quality standards. Also necessary is a clearly defined process that would require state consultation prior to Level 2 testing, or implementation (Level 3 and 4) of the SAMP.

Response: The preferred alternative describes the management actions that are intended to be implemented. The only flow action associated with the preferred alternative is the one-time flow test from Gavins Point Dam that may be implemented after 9 years if determined to be necessary. The process for adjusting actions in the future is clearly laid out in the SAMP including a description of State involvement in the process.

Representative Quotes (Correspondence ID): 3
Comments (Comment ID): 645651

Concern Statement: If an alternative other than Alternative 3 is selected as the preferred alternative in the MRRMP-EIS the process for creating flow changes needs to be clear to stakeholders and comply with the Master Manual. Additionally, any alternative that would require revisions to the Master Manual cannot be considered without a separate NEPA process. The Final MRRMP-EIS should contain procedural protections that will govern

future consideration of any proposed flow modifications or deviations outside the bounds of the Master Manual that will provide for direct consultation with states.

Response: Future USACE implementation of management action under the MRRP will comply with NEPA. Sections 1.5.3 and 4.9 of the EIS describe considerations for future NEPA compliance associated with the scope of the MRRMP-EIS.

Representative Quotes (Correspondence ID): 27, 29, 44, 46, 64, 65, 96, 122, 126, 167, 168, 173, 176, 192, 197, 219, 221, 222, 228

Comments (Comment ID): 626710, 645805, 645755, 645629, 645449, 645291, 645244, 645126, 644793, 644782, 644780, 644745, 643483, 641630, 631574, 627015, 643878, 641385, 640208, 638303, 633771, 633523, 631575, 628523, 626732

Concern Statement: An alternative must be consistent with the eight authorized purposes. USACE has an obligation to meet targets proposed in each Annual Operating Plan. The authorized purposes and the priority purposes of navigation and flood control are under emphasized in the document. Science-based planning can promote these authorized purposes.

Response: The current range of alternatives represents a reasonable range that could be taken in relation to the 2003 BiOp and in relation to the recent effects analysis. The alternatives selected for analysis were developed to meet the objectives and the purpose and need of the MRRMP-EIS. The impacts of the alternatives on resources, including the authorized purposes, were forecasted and compared in the EIS. USACE believes it has identified the plan that achieves species objectives while causing the least amount of impacts to the range of river uses.

Representative Quotes (Correspondence ID): 29, 34, 37, 46, 60, 69, 101, 130, 132, 136, 140, 144, 161, 173, 175, 176, 177, 187, 189, 205, 211, 216, 221, 222, 233

Comments (Comment ID): 646271, 645298, 644779, 644775, 644540, 643420, 643415, 642829, 642140, 642117, 641548, 641400, 641384, 641383, 636861, 634896, 633924, 633867, 633851, 633837, 633825, 631137, 628519, 628518, 628455, 628334, 626715, 641575

Concern Statement: USACE should “frontload” the biological assessment to meet the purpose and objectives of the Draft MRRMP-EIS and include these in the Final MRRMP-EIS.

Response: The best available science remains inadequate to quantify the effects of physical (abiotic) changes to the Missouri River on pallid sturgeon population dynamics, in spite of the availability of the new information since the 2003 Amended BiOp was issued. Efforts to push beyond a basic understanding of the species’ ecology to facilitate predictions of environmental causes and effects on pallid sturgeon are still compromised by fundamental information gaps. Lines of evidence for many of the pallid sturgeon management hypotheses are limited to theoretical deduction, inference from sparse empirical datasets, or expert opinion. The independently-led Effects Analysis came to these conclusions. Given the high level of uncertainty regarding the necessary actions to address the listed species’ needs, USACE and USFWS agreed that proceeding under a rigorous and progressive SAMP, based on the results of the Effects Analysis, would provide the most effective, efficient, and accountable way to manage risks to the species, address key uncertainties, and identify the scope and scale of actions ultimately required to achieve the MRRP objectives without expending resources on actions which prove ineffective.

Representative Quotes (Correspondence ID): 183
Comments (Comment ID): 645991

Concern Statement: USACE should initiate consultation with USFWS. The MRRMP-EIS would benefit from an updated Biological Assessment and subsequent Biological Opinion containing new Reasonable and Prudent Alternatives before any decision is rendered.

Response: Comment noted. This recommendation is consistent with the process that was followed.

Representative Quotes (Correspondence ID): 131, 183, 240
Comments (Comment ID): 645874, 645784, 643962

Concern Statement: Any action which results or is likely to result in dredge or fill in the Missouri River or any tributary to the Missouri River will require a Section 401 permit and possibly a general storm water construction permit. A sovereign land permit application and review by the Office of the State Engineer would be required for ESH construction on the Missouri River and for any requests to restrict human access on Missouri River sandbars in North Dakota.

Response: USACE would comply with CWA Section 401 prior to construction of projects, including ESH construction. This environmental compliance would occur during site-specific project planning.

Representative Quotes (Correspondence ID): 239
Comments (Comment ID): 645788, 645787

Concern Statement: Sand and gravel dredging is discussed in the Draft MRRMP-EIS as an authorized purpose and is not. This should be corrected.

Response: USACE has recognized this error and adjusted the MRRMP-EIS to correct it.

Representative Quotes (Correspondence ID): 242
Comments (Comment ID): 645556

Concern Statement: The Final EIS should state that according to the Master Manual, the Missouri River cannot be managed to benefit the Mississippi River.

Response: This clarification has been added to the Mississippi River section in Chapter 3 of the Final EIS.

Representative Quotes (Correspondence ID): 242
Comments (Comment ID): 645498

Concern Statement: Decisions made through adaptive management must only be made after full NEPA analysis and independent peer review as well as a separate Environmental Impact Statement that contains complete hydrologic and economic modeling. These concerns also relate to the SAMP.

Response: USACE agrees with the commenter in part. As described in Sections 1.5.3 and 4.9, USACE contemplates the need for additional NEPA analyses for actions not contemplated or evaluated in the current MRRMP-EIS. This could include the need for site-specific analyses once locations have been identified for implementation. However, some actions fully analyzed in the MRRMP-EIS could be implemented immediately upon selection of a preferred alternative. For new actions, the level or amount of modelling

and need for independent peer review would be commensurate with the actions being proposed in order to allow for an informed decision under NEPA.

Representative Quotes (Correspondence ID): 228
Comments (Comment ID): 645468

Concern Statement: USACE should be aware of the North Dakota Aquatic Nuisance Species (ANS) policy that is in place when working on waters within our state, and ensure that it is being followed in the implementation of the MRRMP-EIS.

Response: USACE will comply with applicable state and local laws and policies when implementing actions under the MRRMP-EIS.

Representative Quotes (Correspondence ID): 239
Comments (Comment ID): 645403

Concern Statement: Guidance has not been developed for Section 3176 of the Water Resources and Development Act (WRDA) of 2007 which may prove vital in expanding the geographic scope of the MRRMP-EIS. Guidance should be developed for Section 3176 of the WRDA of 2007 that allows USACE to implement actions which, based on science, will avoid jeopardy and contribute to recovery of the listed species - regardless of whether the action is on the Missouri River Mainstem.

Response: Comment noted.

Representative Quotes (Correspondence ID): 239
Comments (Comment ID): 645372

Concern Statement: The MRRMP-EIS should add references to the states and their authorities and recognize state governments as sovereign entities.

Response: States and their authorities and laws are recognized and described in the governance section of the SAMP.

Representative Quotes (Correspondence ID): 239
Comments (Comment ID): 645361

Concern Statement: USACE has failed to fully implement any flow related Reasonable and Prudent Alternative as legally required for the pallid sturgeon in the 2000 and 2003 Biological Opinions from their sister agency, the U.S. Fish and Wildlife Service.

Response: This comment pertains to the 2003 Biological Opinion. Comment noted.

Representative Quotes (Correspondence ID): 238
Comments (Comment ID): 645323

Concern Statement: USACE needs to review the most recent executive order concerning federal actions for projects in flood plains (Executive Order 13960) to determine whether the various environmental flow alternatives comply with current federal requirements.

Response: The policy established in Executive Order 13960 is to improve the Nation's preparedness and resiliency against flooding. The order focuses on occupancy and development of the floodplain. Upon review of Executive Order 13960, USACE will evaluate compliance for any site-specific action and flow adjustment.

Representative Quotes (Correspondence ID): 197
Comments (Comment ID): 645259

Concern Statement: As USACE considers which actions it will ultimately implement, Missouri asserts the agency must ensure that such actions are consistent with existing Congressional authority and established priorities including flood control and navigation. Even though NEPA requires USACE to analyze a broad range of alternatives, most of the alternatives presented in the Draft MRRMP-EIS are inconsistent with USACE's authority given the impacts they would have to flood control and navigation.

Response: USACE intends to continue to serve the authorized purposes of the Missouri River Mainstem Reservoir System. CEQ's NEPA regulations require consideration of reasonable alternatives not within the jurisdiction of the lead agency (40 CFR 1502.14). The EIS includes analysis of impacts for all authorized purposes and a variety of other Human Considerations.

Representative Quotes (Correspondence ID): 197
Comments (Comment ID): 645246

Concern Statement: A deviation from the Master Manual for a one-time flow event is not consistent with USACE's Congressional authority and it should not be pursued.

Response: Comment noted. The process for modifying the Master Manual in the future is dependent upon what specific management action is being contemplated.

Representative Quotes (Correspondence ID): 197
Comments (Comment ID): 645245

Concern Statement: There is a lack of mitigation in the preferred alternative. USACE must include mitigation habitat planning in the MRRMP-EIS.

Response: The need to acquire and develop riparian and aquatic habitat on 166,750 acres of land as authorized by Section 601a of WRDA 1986 and Section 334 of WRDA 1999 and recommended and described in the 2003 ROD for the BSNP Mitigation Project Supplemental EIS is still considered relevant and remains unchanged. Implementation of the Mitigation Project was anticipated to take more than 30 years but an annual rate of implementation was not specified due to budget uncertainty. Due to current and anticipated future administration budget priorities, it is assumed that land acquisition over the 15-year implementation timeframe for the Management Plan would continue to be focused on lands that can be used to meet endangered species objectives while also contributing to BSNP mitigation. Habitat development would be implemented on any acquired lands which would be credited toward the BSNP mitigation requirements. The Draft EIS described the Mitigation Project in Section 1.1.5, discussed its continued relevance in Section 1.4, and described its relationship to the scope of the MRRMP-EIS in Section 1.6. The Final EIS retains this language and USACE has also added BSNP mitigation as part of the Biological Assessment 7(a)(1) Plan.

Representative Quotes (Correspondence ID): 179
Comments (Comment ID): 645228

Concern Statement: USACE is only proposing to avoid jeopardy of the three threatened and endangered species – a much more narrow effort which fails to carry-out the intent of WRDA 2007. The ecosystem nor any of the other native species are no longer a part of the Recovery Program. The legality of this change is questioned.

Response: Section 120 of the Consolidated Appropriations Act of 2012 included language that prohibited USACE from funding MRERP during Fiscal Year (FY) 2012. That Congressional direction has not changed in any subsequent appropriations bill passed

by Congress. USACE acknowledges the scope of the MRRMP-EIS is narrower than the scope of MRERP. However, the need for the MRRMP as described in the Draft EIS remained, and as such, USACE initiated a new EIS process, separate from that which was conducted for MRERP.

Representative Quotes (Correspondence ID): 148, 179, 229
Comments (Comment ID): 645201, 644895, 642648

Concern Statement: If proposed management actions involve actions outside of the scope of the Master Manual, USACE should consult with each basin state.

Response: Comment noted. The governance section of the SAMP describes the process that will be followed during AM implementation including basin state involvement.

Representative Quotes (Correspondence ID): 206, 213, 236
Comments (Comment ID): 645152, 643311, 641735

Concern Statement: USACE should pursue a better understanding with the U.S. Environmental Protection Agency and state natural resource agencies that sediment augmentation is not a pollutant or a violation of the Clean Water Act.

Response: Sediment redistribution as a management action was considered and discussed in Section 2.5.1.14 of the Draft EIS. Based on the results of Phase I of the Lewis and Clark Sediment Management Study, and current prioritization of management hypotheses, this action was eliminated from consideration in the Draft EIS because its effectiveness at contributing towards the species objectives and implementation feasibility has not been demonstrated. Phase II of the Sediment Study is ongoing and the results of that study would be evaluated through the process established in the SAMP. Coordination with the U.S. Environmental Protection Agency would occur in association with any future planning efforts related to implementation of sediment augmentation management actions.

Representative Quotes (Correspondence ID): 206
Comments (Comment ID): 6645135

Concern Statement: Mitigation is only given a role in recovery under Alternative 2. However, this does not include mitigation schedules and requirements which harms the legal meaning of mitigation that would require clarification in other forums.

Response: The need to acquire and develop riparian and aquatic habitat on 166,750 acres of land as authorized by Section 601a of WRDA 1986 and Section 334 of WRDA 1999 and recommended and described in the 2003 ROD for the BSNP Mitigation Project Supplemental EIS is still considered relevant and remains unchanged. Implementation of the Mitigation Project was anticipated to take more than 30 years but an annual rate of implementation was not specified due to budget uncertainty. Due to current and anticipated future administration budget priorities, it is assumed that land acquisition over the 15-year implementation timeframe for the Management Plan would continue to be focused on lands that can be used to meet endangered species objectives while also contributing to BSNP mitigation. Habitat development would be implemented on any acquired lands which would be credited toward the BSNP mitigation requirements. The Draft EIS describes the Mitigation Project in Section 1.1.5, discussed its continued relevance in Section 1.4, and describes its relationship to the scope of the MRRMP-EIS in Section 1.6. The Final EIS retains this language and USACE has also added BSNP mitigation as part of the Biological Assessment 7(a)(1) Plan.

Representative Quotes (Correspondence ID): 166
Comments (Comment ID): 644930

Concern Statement: There is concern with the lack of specific actions related to acquiring and developing lands associated with the Bank Stabilization and Navigation Project (BSNP) Mitigation Project authorities in the Draft MRRMP-EIS and the current preferred alternative. The MRRMP-EIS should reflect USACE duty to fulfill its obligations under the Mitigation Project and provide details describing how this part of the mission will be accomplished. To date the obligations of the BSNP Mitigation Project have not been completed but are still relevant and remain unchanged. Further efforts should be made to complete the authorized mitigation for this habitat loss pursuant to Section 5018 of the Water Resources Development Act.

Response: The need to acquire and develop riparian and aquatic habitat on 166,750 acres of land as authorized by Section 601a of WRDA 1986 and Section 334 of WRDA 1999 and recommended and described in the 2003 ROD for the BSNP Mitigation Project Supplemental EIS is still considered relevant and remains unchanged. Implementation of the Mitigation Project was anticipated to take more than 30 years but an annual rate of implementation was not specified due to budget uncertainty. Due to current and anticipated future administration budget priorities, it is assumed that land acquisition over the 15-year implementation timeframe for the Management Plan would continue to be focused on lands that can be used to meet endangered species objectives while also contributing to BSNP mitigation. Habitat development would be implemented on any acquired lands which would be credited toward the BSNP mitigation requirements. The Draft EIS described the Mitigation Project in Section 1.1.5, discussed its continued relevance in Section 1.4, and described its relationship to the scope of the MRRMP-EIS in Section 1.6. The Final EIS retains this language and USACE has also added BSNP mitigation as part of the Biological Assessment 7(a)(1) Plan.

Concern Statement: The integrity of the channel remains the primary responsibility until obviated by Congress.

Response: Site-specific planning and design of IRC projects would take into account the need to maintain the authorized navigation channel.

Representative Quotes (Correspondence ID): 222
Comments (Comment ID): 644815

Concern Statement: The States have sovereign right to their real estate and actions that compromise that real estate, and the decisions relating to real estate resources, represent a federal takings related to States' real estate and resource assets.

Response: Comment noted.

Representative Quotes (Correspondence ID): 222
Comments (Comment ID): 644781

Concern Statement: Elimination or significant modification of BSNP Mitigation Project activities from the MRRP would seem to constitute a major program change. Without a

component of the BSNP Mitigation Project dedicated to sport and other native, non-endangered species, it is unclear how such program changes might continue to meet USACE's responsibility for compensatory mitigation from the BSNP project.

Response: The need to acquire and develop riparian and aquatic habitat on 166,750 acres of land as authorized by Section 601a of WRDA 1986 and Section 334 of WRDA 1999 and recommended and described in the 2003 ROD for the BSNP Mitigation Project Supplemental EIS is still considered relevant and remains unchanged. Implementation of the Mitigation Project was anticipated to take more than 30 years but an annual rate of implementation was not specified due to budget uncertainty. Due to current and anticipated future administration budget priorities, it is assumed that land acquisition over the 15-year implementation timeframe for the Management Plan would continue to be focused on lands that can be used to meet endangered species objectives while also contributing to BSNP mitigation. Habitat development would be implemented on any acquired lands which would be credited toward the BSNP mitigation requirements. The Draft EIS described the Mitigation Project in Section 1.1.5, discussed its continued relevance in Section 1.4, and described its relationship to the scope of the MRRMP-EIS in Section 1.6. The Final EIS retains this language and USACE has also added BSNP mitigation as part of the Biological Assessment 7(a)(1) Plan.

Representative Quotes (Correspondence ID): 177
Comments (Comment ID): 644635

Concern Statement: In Section 2.3, Table 10 needs to include a reference regarding Wild and Scenic Rivers Act Section 7 consultation with NPS for actions within the Missouri National Recreation River.

Response: Although Table 10 in Section 2.3 of the SAMP does not specifically call out Wild and Scenic River Act consultation with NPS, it does include a row on page 73 for agencies outside of the MRRIC collaborative process. Although NPS is a member of MRRIC, the participation on MRRIC does not obviate the need for USACE to consult with NPS on potential impacts to the Missouri National Recreational River under the Wild and Scenic Rivers Act. See Section 2.3.8.2 for the specific reference to consultation with NPS under Section 7 under the Act.

Representative Quotes (Correspondence ID): 183
Comments (Comment ID): 643961

Concern Statement: USACE must ensure continued consideration be given to the Emergent Sandbar Management Planning Approach and Management Plan for management actions within the Missouri National Recreation River.

Response: As described in Sections 6.11 of the MRRMP-EIS, USACE understands its requirements under Section 7 of the Wild and Scenic Rivers Act and is committed to complying with the law related to actions contemplated within the Missouri National Recreational River.

Representative Quotes (Correspondence ID): 183
Comments (Comment ID): 643954

Concern Statement: Outstandingly Remarkable Values must be protected under Section 10(a) of the Wild and Scenic Rivers Act. NPS manages the Missouri National Recreation River to protect and enhance for present and future generations Outstandingly Remarkable

Values which are reviewed for consistency with the anti-degradation policy in Section 10(a) of the Wild and Scenic Rivers Act.

Response: USACE will comply with Section 10 of the Wild and Scenic River Act.

Representative Quotes (Correspondence ID): 183
Comments (Comment ID): 643949

Concern Statement: Activities proposed in the MRRMP-EIS that meet the criteria for a federally assisted water resources project and are located within the Missouri National Recreational River will require a Section 7(a) determination prior to implementation.

Response: USACE understands its obligation under Section 7 of the Wild and Scenic Rivers Act and will coordinate with NPS on projects that could impact the Missouri National Recreational River.

Representative Quotes (Correspondence ID): 183
Comments (Comment ID): 643948

Concern Statement: The Final MRRMP-EIS must fully disclose how USACE will meet their Fish and Wildlife Coordination Act mitigation responsibilities for all native fish and wildlife species habitat on the river during implementation of the MRRP, and consider the adverse impacts to non-federally listed species by focusing habitat mitigation to only listed species for the next 15 years.

Response: The need to acquire and develop riparian and aquatic habitat on 166,750 acres of land as authorized by Section 601a of WRDA 1986 and Section 334 of WRDA 1999 and recommended and described in the 2003 ROD for the BSNP Mitigation Project Supplemental EIS is still considered relevant and remains unchanged. Implementation of the Mitigation Project was anticipated to take more than 30 years but an annual rate of implementation was not specified due to budget uncertainty. Due to current and anticipated future administration budget priorities, it is assumed that land acquisition over the 15-year implementation timeframe for the Management Plan would continue to be focused on lands that can be used to meet endangered species objectives while also contributing to BSNP mitigation. Habitat development would be implemented on any acquired lands which would be credited toward the BSNP mitigation requirements. The Draft EIS described the Mitigation Project in Section 1.1.5, discussed its continued relevance in Section 1.4, and described its relationship to the scope of the MRRMP-EIS in Section 1.6. The Final EIS retains this language and USACE has also added BSNP mitigation as part of the Biological Assessment 7(a)(1) Plan.

Representative Quotes (Correspondence ID): 183
Comments (Comment ID): 643938

Concern Statement: The "Water Rights" section does not mention state water rights.

Response: Section 6.5 of the EIS has been revised to describe state water rights in addition to the current discussion of Tribal water rights.

Representative Quotes (Correspondence ID): 239
Comments (Comment ID): 643033

Concern Statement: The Department of Agriculture rule under the Farmland Protection Policy Act requires USACE to examine the potential impacts of the proposed actions, and if there are adverse effects on farmland preservation, to consider alternatives to lessen the

adverse effects. Additionally, the agencies should evaluate the conversion of prime farmland to fallow land or habitat mitigation through land acquisitions for projects.

Response: As described in Section 6.7 of the MRRMP-EIS, USACE will work with USDA before implementation of site-specific projects where Management Plan actions have the potential to convert farmland to non-agricultural uses. Additional information on the conversion of farmland from land acquisition is described in Section 3.10.

Representative Quotes (Correspondence ID): 220
Comments (Comment ID): 642149, 642148

Concern Statement: Pursuant to 7 CFR 1468.6, USACE must obtain prior authorization from the Natural Resources Conservation Service (NRCS) for any activities that will impact NRCS easement lands.

Response: USACE is working with the NRCS and willing seller land owners to ensure lands under NRCS easements are co-managed in a way that can accomplish the missions of both agencies.

Representative Quotes (Correspondence ID): 186
Comments (Comment ID): 641527

Concern Statement: USACE has sources of authority to increase significantly its habitat restoration projects and to provide efficacy and effectiveness to the restoration process for ecological and hydrological function activities that will also provide more room for the river and thereby reduce flood risk.

Response: The MRRMP-EIS and Draft SAMP include the creation of IRC habitat, spawning habitat, emergent sandbar habitat and associated research to address the habitat needs of the pallid sturgeon and terns and plovers. The SAMP outlines a process that could lead to increased habitat creation if deemed necessary.

Concern Statement: The State of North Dakota tentatively supports the preferred alternative under specific conditions including: reconvening consultation, preparation of a new EIS for any changes to the Master Manual, and a commitment to complying with all state laws and regulatory requirements.

Response: Comment noted.

Representative Quotes (Correspondence ID): 96
Comments (Comment ID): 640189

Concern Statement: Dike notching is unlawfully taking private land without compensation which is violating the 5th amendment.

Response: The 5th Amendment of the US Constitution states that private property will not be taken for public use without just compensation. The US Supreme Court has ruled on more than 50 cases and has set out criteria to be used when determining if an unlawful taking of property has occurred. If takings claims were to occur, each claim would be analyzed based on site-specific and factual findings.

Representative Quotes (Correspondence ID): 90
Comments (Comment ID): 636824

Concern Statement: A degree of uncertainty in the science associated with the three threatened and endangered species should not be used to obfuscate the intent of Section 7 of the Endangered Species Act.

Response: The purpose of the Endangered Species Act as defined in Section 2(b) is to “provide a means whereby the ecosystems upon which endangered species and threatened species depend may be conserved, to provide a program for the conservation of such endangered species and threatened species, and to take such steps as may be appropriate to achieve the purposes of the [specific] treaties and conventions.” In meeting its Section 7 obligations to “insure that its actions are not likely to jeopardize the continued existence of any endangered or threatened species or result in the destruction or adverse modification of designated critical habitat,” USACE has proposed actions thought to be necessary to reduce the effects of the operations of the Missouri River system on listed species. USACE recognizes the complexity of the system and that additional information may be needed to provide more certainty that if program funding is expended, measurable improvements will occur. In order to be transparent and lay out a structured approach to improving conditions for affected listed species, USACE has developed the SAMP in order to set priorities for gaining more information and reducing uncertainty while implementing actions to meet listed species objectives as defined by USFWS.

HH1000 *Hydrology and Hydraulics*

Concern Statement: The flood control and interior drainage modeling was completed for only four levee sites in the entire floodplain. The Draft EIS stated economic impacts are a fraction of total economic impacts because the flow management actions on interior drainage are missing from the analysis. This omission makes the Draft EIS incomplete and renders any claim of accurately predicted impacts of all six alternatives invalid. USACE should complete hydrologic modeling peer reviewed comprehensive economic impact studies for the entire floodplain before any flow management action is completed.

Response: The analysis conducted for interior drainage is adequate for determining the impacts of the alternatives. The assumptions and limitations of the analysis are clearly presented in the Final EIS.

Representative Quotes (Correspondence ID): 98, 154, 173, 211, 228
Comments (Comment ID): 633687, 645630, 645523, 642137, 640943

Concern Statement: Under Alternative 4, the flow model may need calibration. The 126,000 cfs proposed results in flooding immediately downstream from Kansas City and substantially increases flood risks during the timeframe required for the pulse to clear the mouth of the river.

Response: The flood constraints were established so the ESH releases have an opportunity to run during the period of record. The Human Considerations analyses evaluate the impacts of those flows on Flood Risk throughout the basin.

Representative Quotes (Correspondence ID): 228
Comments (Comment ID): 645558

Concern Statement: Hydrologic modeling and peer reviewed comprehensive economic impact studies must be completed before any flow management action is implemented. The possible implementation of a one-time spawning cue release 9-10 years in the future allows adequate time to complete a full analysis of the impacts to stakeholders.

Response: The following text has been inserted within the EIS, Section 3.12.2.1, Impacts Assessment Methodology:

The Missouri River system as currently operated provides substantial flood damage reduction and benefits to the entire basin. Study alternatives include modifying operations of the Missouri River reservoir system with both higher and lower reservoir releases during select periods for species habitat benefits. The current HEC-ResSim and HEC-RAS analysis shows the potential for negative impacts to flood damage reduction for alternatives that include changes in reservoir flow releases. The current study methodology, which employs an 82-year period of record, is suitable for alternative comparison and providing an indication of change in flood risk. However, the methodology does not simulate a sufficient number of events and possible runoff combinations within the large Missouri River basin to evaluate potential change in downstream flood risk. Prior to implementing any management action that alters reservoir operations, a comprehensive flood risk evaluation will be conducted per USACE requirements. The level of additional hydrologic analysis will be based on USACE guidance and requirements and will identify the change in reservoir pool probability, reservoir release frequency, river stage-frequency, and river stage-duration.

Representative Quotes (Correspondence ID): 228
Comments (Comment ID): 645467

Concern Statement: Flow modeling for the alternatives is incomplete and inaccurate and the No Action alternative does not serve as an appropriate baseline for comparison of alternatives. The approach used for modeling the No Action alternative as the baseline sets false expectations for future management scenarios and inflates the value of the baseline alternative to pallid sturgeon. USACE should consider modeling the alternative based on actual historic conditions and operations of the reservoirs. This will encompass the actual variability in flows and allow for a more realistic implementation, set of alternatives, and SAMP.

Response: Reservoir operations and basin conditions have changed throughout the period of record (e.g., reservoirs were closed at different times, operational criteria has been updated, etc.). In order to estimate impacts that occur due to the operational changes in the various alternatives, each alternative, including the No Action, needs to have the same operational criteria when not operating for an alternative's specific criteria (e.g., ESH release, spawning cue, etc.). To accomplish this, a No Action simulation representing the current reservoir operations under the current basin conditions needed to be created. Although the modeled results for each alternative will not capture all of the real-time decisions and adjustments, the impacts provide an assessment of the differences between modeled alternatives.

Representative Quotes (Correspondence ID): 122, 238
Comments (Comment ID): 645331, 638390

Concern Statement: The use of averages and the 82-year period of record which includes years with major high- and low-water events is not appropriate and minimizes the damages caused during these years from flooding and severe drought and understates the impacts of the alternatives.

Response: Comment noted. The Final EIS discloses that large impacts could occur in certain years that may not be evident in reported average values.

Representative Quotes (Correspondence ID): 168, 176
Comments (Comment ID): 645173, 645172, 644752

Concern Statement: A hydraulic model should be created for the river reach from Oahe Dam to Lake Sharpe so that channel capacity information can be included when assessing potential impacts of various flows.

Response: USACE considered the need for a separate HEC-RAS model in the reach downstream of Oahe dam. The open river portion of this reach is very short. Due to the limited number of human considerations in this reach, USACE determined that the Oahe release and Big Bend reservoir pool level were adequate to represent alternative variability. These values are available from the ResSim model output for all alternatives.

Representative Quotes (Correspondence ID): 206
Comments (Comment ID): 645138

Concern Statement: The Dredgers continue to object to the HEC-RAS model being used for regulatory purposes relating to permits and decision making regarding bed degradation. USACE repeatedly agreed in MRRIC sessions to note that this data should not be used for regulatory purposes. The note is absent from the document and therefore skews the decision-making prospects. The agreed to note on modeling should be added.

Response: HEC-RAS is designed to perform one-dimensional hydraulic calculations for a full network of natural and constructed channels. The purpose of the HEC-RAS models was to create a baseline that represents current river conditions and to provide a tool to evaluate potential hydraulic changes resulting from proposed management actions or alternatives (e.g., channel reconfiguration and/or flow management). HEC-RAS is used extensively throughout the world and is an appropriate model for this EIS.

In addition to the HEC-RAS analyses referenced above, a separate analysis was conducted to assess the impact that changing flow releases in accordance with the alternatives could have on sediment accumulation rates in the dredging segments. While this analysis utilized the flow routing capability of the HEC-RAS model to determine flows for the various alternatives, the evaluation was a gage analysis based on rating curves rather than a modeling exercise. It used the change in sedimentation rates from seven U.S. Geological Survey (USGS) gages located at different points between St. Joseph and Hermann, Missouri as the basis for the impact assessment. The technical basis and limitations for this analysis is further described in the supporting document "Commercial Sand and Gravel Dredging Environmental Consequences Analysis Technical Report" which is available online (www.moriverrecovery.org).

Representative Quotes (Correspondence ID): 222
Comments (Comment ID): 644785

Concern Statement: The use of years in the 82-year period of record where the government mandated artificial regulatory action that diminished the presence of navigation on the

Missouri river should be excluded from modeling. The use of these years understates the benefits of navigation in the MRRMP-EIS.

Response: Comment noted. Use of the referenced years do not affect the ability to estimate relative impacts from implementing the different alternatives.

Representative Quotes (Correspondence ID): 176
Comments (Comment ID): 644753

Concern Statement: The Draft MRRMP-EIS has numerous flaws in the economic and hydrologic modeling utilized to measure impacts. The data derived from these models is either insufficient or inaccurate and the economic impacts are understated and the limitations are not defined.

Response: USACE believes the analysis conducted is adequate and limitations of the modeling are well documented in the EIS. The models are a planning tool meant to estimate impacts from implementation of the various alternatives rather than a tool to exactly approximate observed or actual conditions.

Representative Quotes (Correspondence ID): 176
Comments (Comment ID): 644750

Concern Statement: The MRRMP-EIS should confirm modeling low flow elevations with actuals and consider potential model inaccuracies when evaluating additional impacts. There could be greater impacts than projected which could increase the costs in the MRRMP-EIS and possibly compromise transmission grid reliability.

Response: The HEC-RAS model is based on the best available channel survey information and is calibrated to 2012 conditions. Local effects on stage due to temporary changes in river conditions, including ice jams, ice cover, and transient sandbar dynamics, are not included within the HEC-RAS model. These temporary effects often cause river stage changes of several feet. However, for the purposes of alternative comparison, including transient effects is not relevant (e.g., the formation of an ice jam has the same effect on all alternatives). All constructed models were calibrated to the same period through 2012. Calibration accuracy within this reach varies by location but is generally within 0.5 to 1 foot accuracy for normal and low flows. Model calibration within the Garrison to Oahe reach is discussed in the supporting documents, HEC-RAS Calibration Report, which is available online (www.moriverrecovery.org). We acknowledge that the model accuracy at specific locations may be disputed by local information. However, we believe that model results are suitable to use for this analysis. The EIS methodology employs an 82-year period of record with current water development conditions to evaluate differences between alternatives. Use of the extensive 82-year period allows for reasonable alternative impact evaluation for a wide range of flow events.

Representative Quotes (Correspondence ID): 167
Comments (Comment ID): 643876

Concern Statement: It is unclear if recommendations made by Montana-Dakota Utilities Company related to the flow level at which the Heskett unit is expected to encounter a shutdown were included. USACE should take a close evaluation of the model in the Heskett reach and review actual elevation measurements to ensure the model is accurately predicting low flows for facilities. If shutdown events occur with higher flows than currently described by the model, the impacts should be reflected in the alternatives.

Response: During the EIS modeling and evaluation process, numerous conversations were conducted with Heskett personnel. Shutdown criteria was adjusted during this process as a result. The information used in the Draft EIS analysis and presented results incorporated input from Heskett personnel.

Comments (Comment ID): 643859

AL700 *Alternatives: Actions Common to All Alternatives*

Concern Statement: Current science does not indicate that implementation of a spring rise will benefit the pallid sturgeon and the inclusion of a spring rise in any of the alternatives presents an unacceptable flood risk.

Response: Alternatives 1, 2, and 6 contain a spring pulse meant to cue pallid sturgeon spawning. Alternative 4 contains a spring pulse meant to create emergent sandbar habitat for birds. Alternative 5 contains a fall pulse meant to create emergent sandbar habitat for birds. Alternative 3 contains a one-time flow test of the spring pallid sturgeon spawning cue pulse. The criterion for pulsed flow magnitude in alternative 6 is the observation cited in the Effects Analysis that reproductive pallid sturgeon in the upper River would migrate up the Yellowstone or Missouri in response to flow pulses that were roughly 2 times the background discharge rate or higher. Under Alternative 3, if the flow pulses occurring during the 9 years are not sufficient to test the hypothesis, flow pulses up to the flow values assessed alternative 6 could be used as a one-time experiment. Current science cannot prescribe the exact magnitude or duration of a spring pulse beneficial to pallid sturgeon. Through proper implementation of adaptive management, if a spring pulse is found to be important to the pallid sturgeon, the one-time spawning cue test will be scientifically designed to elicit meaningful results. The preferred alternative includes nine years of study of existing spring pulses from intervening tributary flows to better understand pallid sturgeon responses. Combined with existing data, it is possible this will be sufficient to determine if a spring pulse is necessary and the one-time test may not be needed.

Representative Quotes (Correspondence ID): 20, 168
Comments (Comment ID): 626651

Concern Statement: Oppose any alternative that includes flow modifications and increases downstream flood risks and jeopardizing the integrity of existing levee systems.

Response: Comment noted. The preferred alternative includes nine years of study of existing spring pulses from intervening tributary flows to better understand pallid sturgeon responses. Combined with existing data, it is possible this will be sufficient to determine if a spring pulse is necessary and the one-time test may not be needed.

Representative Quotes (Correspondence ID): 35, 46, 59, 61, 66, 71, 93, 130, 132, 136, 138, 144, 154, 168, 173, 176, 211, 222, 228, 246
Comments (Comment ID): 628391, 628449, 632125, 628571, 632127, 633525, 633676, 633807, 633831, 633838, 633839, 633853, 633914, 635245, 635262, 640481, 641386, 642132, 644738, 644747, 644762, 644829, 645157, 640728, 640734, 645791

Concern Statement:

- Modifications in flow as presented in Alternatives 2, 4, 5 and 6 undermine the primary congressionally authorized purposes of navigation and flood control.

- The states of Missouri, Kansas, Iowa, and Nebraska own the bed of the lower river. The states have a sovereign right to their real estate and federal actions that compromise the real estate resources are a takeover in regard to states real estate and natural resources.
- The use of the HEC-RAS model for decision making in the Draft EIS is flawed. Commercial sand dredgers have continually presented their objections to HEC-RAS being used for any permitting related decisions and USACE has previously agreed during MRRIC sessions. In the Draft EIS; however, this important point is missing from the document and needs to be included in the content for this section.
- The Draft EIS fails to address the issue of sediment in the system and the lack of material movement.
- Regarding IRC construction and maintenance, USACE must give commercial sand dredgers absolute assurance that these new habitat areas will not impact their operations by making its related regulatory strategy clear.

Response: Alternatives 2, 4, 5 and 6 were not identified as preferred alternatives, in part, because of the estimated impacts to other river uses including support for authorized purposes such as flood control and navigation. Under Alternative 3, coordination with the states would occur in conjunction with any site-specific project including coordination regarding sovereign lands and any potential state permits that would be required. The use of HEC-RAS models in this planning study is appropriate and the models have undergone several rounds of internal and external review and deemed to be acceptable for planning purposes. No permitting related decisions are being made as part of the Management Plan process – permitting decisions are made by USACE Regulatory and are not the purview of the Management Plan EIS which is focused on evaluating actions for USACE endangered species act compliance. The Draft EIS acknowledges sediment related issues in Section 3.2.1.4, although no sediment related actions such as sediment bypass are planned at this time. Through proper implementation of adaptive management, a sediment bypass or augmentation action could be introduced in the future if sediment related management actions are determined to be required to remove a limiting factor for the listed species.

Representative Quotes (Correspondence ID): 228
Comments (Comment ID): 645512

Concern Statement: The proposed flow events will use water from the carryover storage pool which navigation depends upon during times of water shortage.

Response: Comment noted. Alternatives 2, 4, 5 and 6 were not identified as preferred alternatives, in part, because of the estimated impacts to other river uses including support for authorized purposes such as flood control and navigation. The preferred alternative includes nine years of study of existing spring pulses from intervening tributary flows to better understand pallid sturgeon responses. Combined with existing data, it is possible this will be sufficient to determine if a spring pulse is necessary and the one-time test may not be needed.

Representative Quotes (Correspondence ID): 46
Comments (Comment ID): 628530

Concern Statement: Implementation of any alternative which includes environmental flows much be done within current flood control constraints.

Response: Alternatives 2, 4, 5 and 6 were not identified as preferred alternatives, in part, because of the estimated impacts to other river uses including support for authorized purposes such as flood control. The preferred alternative includes nine years of study of existing spring pulses from intervening tributary flows to better understand pallid sturgeon responses. Combined with existing data, it is possible this will be sufficient to determine if a spring pulse is necessary and the one-time test may not be needed.

Representative Quotes (Correspondence ID): 46
Comments (Comment ID): 628578

Concern Statement: Because the river flow within Missouri is highly variable due to localized rain events there is no need for additional water to be released from Gavins Point Dam.

Response: The preferred alternative includes nine years of study of existing spring pulses from intervening tributary flows to better understand pallid sturgeon responses. Combined with existing data, it is possible this will be sufficient to determine if a spring pulse is necessary and the one-time test may not be needed.

Representative Quotes (Correspondence ID): 29
Comments (Comment ID): 638525

Concern Statement: Each of the alternatives relax current flood control constraints within the Master Manual in an effort to provide flow support to the pallid sturgeon. We believe the only way USACE can implement flow changes is through a Master Manual revision, of which we have long opposed.

Response: This is true of alternatives 2, 4, 5, and 6. The preferred alternative includes nine years of study of existing spring pulses from intervening tributary flows to better understand pallid sturgeon responses. Combined with existing data, it is possible this will be sufficient to determine if a spring pulse is necessary and the one-time test may not be needed. Additional HH analyses will be conducted if AM identifies the need for future flow measures. Prior to implementing any management action that alters reservoir operations, a comprehensive flood risk evaluation will be conducted per USACE requirements. The level of additional hydrologic analysis will be based on USACE guidance and requirements and will identify the change in reservoir pool probability, reservoir release frequency, river stage-frequency, and river stage-duration.

Representative Quotes (Correspondence ID): 98
Comments (Comment ID): 633682

Concern Statement: Flow modifications common to Alternatives 2, 4, 5 and 6 are opposed, especially the low flow provisions of Alternative 2 which will create a split season for the Missouri River navigation industry.

Response: Alternatives 2, 4, 5 and 6 were not identified as preferred alternatives, in part, because of the estimated impacts to other river uses including support for authorized purposes such as flood control. The preferred alternative includes nine years of study of existing spring pulses from intervening tributary flows to better understand pallid sturgeon responses. Combined with existing data, it is possible this will be sufficient to determine if a spring pulse is necessary and the one-time test may not be needed.

Representative Quotes (Correspondence ID): 64, 176
Comments (Comment ID): 633519, 644744

Concern Statement: For successful recovery of the pallid sturgeon a spring rise and fall must be simulated.

Response: Current information does not indicate that pallid sturgeon require a spring pulse to spawn although this is one hypothesis being tested. Spawning is currently occurring – best evidence shows documented reproduction occurred in 2014 during a “flat” hydrograph. A spring pulse does not appear to be needed to provide food – there is little evidence that pallid sturgeon of any size are food-limited in the Missouri River.

The preferred alternative includes nine years of study of existing spring pulses from intervening tributary flows to better understand pallid sturgeon responses. Combined with existing data, we believe this will be sufficient to determine if a spring pulse is necessary.

Representative Quotes (Correspondence ID): 68
Comments (Comment ID): 633531

Concern Statement: USACE should not rush into construction of 12 IRCs for the pallid sturgeon, but rather should construct an initial one and monitor before committing to build the others.

Response: A scientifically designed approach is needed to understand if drifting embryos can be intercepted from the swift, deep thalweg into food-producing areas where larvae can feed and grow. An analysis indicated that 12 sites could provide a statistically meaningful response to test this hypothesis (see Appendix E of the SAMP).

Representative Quotes (Correspondence ID): 98, 130, 132, 135, 136, 140, 144, 145, 154, 173, 175, 205, 211, 222, 228, 246
Comments (Comment ID): 633689, 633823, 633836, 633849, 633866, 633922, 637269, 637643, 640485, 640756, 641392, 641399, 645848, 644789, 644809, 644810, 645470

Concern Statement: Natural flow events should be used to improve our scientific understanding, there is no need for additional flow to be released from Gavins Point.

Response: The preferred alternative includes nine years of study of existing spring pulses from intervening tributary flows to better understand pallid sturgeon responses. Combined with existing data, we believe this will be sufficient to determine if a spring pulse is necessary.

Representative Quotes (Correspondence ID): 69, 162, 241
Comments (Comment ID): 635141, 641166, 640500

Concern Statement: The one-time flow event of the preferred alternative is not supported because it has not been modeled nor were impacts properly assessed.

Response: Impacts from the one-time flow event would fall between the range of impacts seen for the spring pulse under Alternative 6. Modeling the one-time event as part of alternative 3 would not provide any additional information beyond what has already been modeled for Alternative 6. Alternative 3 is a one-time occurrence of a spring pulse equal to the pulse modeled under Alternative 6. Note that the preferred alternative includes nine years of study of existing spring pulses from intervening tributary flows to better understand pallid sturgeon responses. Combined with existing data, we believe this will be sufficient to determine if a spring pulse is necessary.

Representative Quotes (Correspondence ID): 29
Comments (Comment ID): 638526

Concern Statement: Alternative 2 would achieve the upper end of the BiOp restoration goal, while Alternatives 3–6 would achieve about a third of the habitat created by this alternative.

Response: The amount of early life stage habitat (shallow water habitat) under Alternatives 1 and 2 are a reflection of acreage goals in the 2003 Biological Opinion. The amount of early life stage habitat in Alternatives 3–6 are a reflection of what is needed for determining effectiveness of the IRC action and additional amounts of IRC that would be built if the Management Action is deemed effective. Alternatives 1 and 2 represent a different management approach than Alternatives 3–6 because the habitat goals and types described in Alternatives 1 and 2 were written in 2003, before the recent effects analysis. The habitat types and goals reflected in Alternatives 3–6 incorporate more recent guidance from USFWS and the results of the effects analysis. It is rational to predict the effects of the current course of action (the range of future implementation of the current BiOp is reflected by Alternatives 1 and 2) and compare these to new courses of action.

Representative Quotes (Correspondence ID): 63
Comments (Comment ID): 640076

Concern Statement: The Draft EIS fails to provide the information needed by the public to adequately assess the range of alternatives presented.

Response: Species recovery for least terns, piping plovers, and pallid sturgeon are addressed in their respective recovery plans developed by USFWS. The species objectives given to USACE by USFWS for the Management Plan and the actions presented in the alternatives are consistent with the species recovery plans. The objectives and actions are designed to contribute to species recovery keeping in mind that USACE responsibility is to avoid jeopardy to the three species. USACE believes the analysis presented in Chapter 3 is sufficient for the public to compare the effects of the different alternatives especially considering the uncertainties regarding pallid sturgeon recruitment failure. The analysis presents what is known from the best available science and predicts the potential outcomes of the management actions based on what is currently known. A comprehensive SAMP has been developed to adjust these actions as more is learned in the future. The summary table in the Final EIS is consistent with the text in Chapters 2 and 3 of the EIS. The summary table in the Draft EIS was also consistent with the text in Chapter 3 of the EIS. It was described as a summary table and pointed the reader to Chapter 3 for the full analysis of the resources evaluated in the EIS.

Representative Quotes (Correspondence ID): 131
Comments (Comment ID): 640113

Concern Statement: Restored ecosystem acres with predictable flow modifications would do more for recovery of the listed species than the proposed management actions and also reduce flood risk.

Response: USACE used the Purpose, Need, and Objectives to design a reasonable range of alternatives. The purpose of meeting ESA responsibilities does not free USACE from other responsibilities or from considering the impacts of ESA related actions in the decision-making process. USACE has identified a preferred alternative that attempts to

identify and correct limiting factors in the ecosystem that are causing jeopardy. USACE selected the alternative that met the species objectives and had the least detrimental impacts across a range of interests. This decision is fully explained in Section 2.9 of the Final EIS along with a full listing of all the interest categories that were considered in the decision-making process.

Representative Quotes (Correspondence ID): 131
Comments (Comment ID): 640166

Concern Statement: Oppose any alternative that would alter flow levels of the Missouri River and impact domestic water supplies, drainage, irrigation, and transportation.

Response: The preferred alternative does not include reoccurring flow alterations. It does include nine years of study of existing spring pulses from intervening tributary flows to better understand pallid sturgeon responses. Combined with existing data, we believe this will be sufficient to determine if a spring pulse is necessary.

Representative Quotes (Correspondence ID): 161
Comments (Comment ID): 641113, 641131

Concern Statement: Alternatives that use shallow water habitat actions need to reduce sediment effects on downstream water quality.

Response: Potential downstream sediment impacts will be examined for each channel modification project and if sediment impacts are identified then ways to reduce impacts will be examined. Each project will also include State Section 401 water quality certification.

Representative Quotes (Correspondence ID): 161
Comments (Comment ID): 641121

Concern Statement: Lower pool levels provide more flexibility with water storage and releases and will permit real reservoir unbalancing in more years.

Response: Lowering the base of the annual flood control zone does provide additional flood control storage. However, since that target level stays the same from year to year, runoff received during a given year still needs to be evacuated from the reservoir system prior to the start of the next year's runoff season. Lower reservoir levels have negative impacts on other authorized purpose such as navigation, hydropower, and recreation. Changing target levels from year to year is not feasible given the uncertainty about runoff that will be received in a given year.

Representative Quotes (Correspondence ID): 180
Comments (Comment ID): 641443

Concern Statement: USACE is encouraged to select management actions that will benefit a wide range of Missouri River fish and wildlife species.

Response: The actions in the preferred alternative would have benefits to fish and wildlife species beyond just the three listed species. Those benefits are described in the Fish and Wildlife section of Chapter 3 in the EIS.

Representative Quotes (Correspondence ID): 180
Comments (Comment ID): 641449

Concern Statement: Pallid sturgeon recommendations should be prioritized for implementation, including Level 1 and Level 2 research activities.

Response: Concur. The preferred alternative follows this suggested approach.

Representative Quotes (Correspondence ID): 194, 212
Comments (Comment ID): 641712, 641733

Concern Statement: A more accurate description of the alternative development process involving MRRIC and its role needs to be included in the Final EIS.

Response: The description of the alternatives development process in the Draft EIS is an accurate representation of the process that was followed. The alternatives development process was collaborative and transparent. USACE acknowledges that some aspects of the process involved higher degrees of collaboration than others. The acronym ProACT stands for (1) **P**roblem definition, (2) **O**bjectives, (3) **A**lternatives, (4) **C**onsequences, and (5) **T**radeoffs. MRRIC was engaged in each step of the process. The problem statement was shared with MRRIC and MRRIC's input was included in the final version of the problem statement and included in the EIS. Species objectives were shared with MRRIC and were evaluated by ISAP. ISAP comments and MRRIC feedback were considered and incorporated where appropriate into the final versions of the objectives. While it is true that individual MRRIC members or MRRIC as a whole did not design elements of the alternatives such as specific types of habitats, or flow management actions, the alternatives were developed by USACE using the results of the effects analysis which was reviewed extensively by ISAP and MRRIC. MRRIC was involved in evaluation of test alternatives and in two rounds of proxy analyses of consequences and tradeoffs. Individual MRRIC members and MRRIC as a committee have had opportunity to provide comment or recommendation regarding the process and its outcome from 2012 to the present.

Representative Quotes (Correspondence ID): 148
Comments (Comment ID): 642704

Concern Statement: The entire fisheries community would benefit from regular floodplain connectivity and it can assist with reduced flood risk.

Response: The actions in the EIS are designed to fulfill endangered species act responsibilities although a variety of fish and wildlife species would benefit as outlined in Chapter 3 of the EIS. Best available science at this time does not indicate that pallid sturgeon of any age are food limited or that floodplain connectivity would increase pallid sturgeon spawning habitat. USACE coordinated with USFWS during development of Alternative 2 to identify criteria for clarification of the floodplain connectivity language from the 2003 BiOp. The 2003 BiOp did not contain numeric criteria for floodplain connectivity. USFWS provided these criteria in a Planning Aid Letter submitted to USACE on November 5, 2015. The criteria stated that the management action should maximize floodplain habitat by ensuring that 77,410 acres of connected floodplain are inundated at a 20 percent annual chance exceedance. This acreage amount was an interpretation, made in 2015, of the language from the 2003 BiOp developed to inform alternatives development. USACE conducted HEC-GeoRAS mapping to determine the acres of existing floodplain connectivity in the lower Missouri River. This was the first time this type of an analysis had been done. The mapping results indicated that 147,650 acres of floodplain connectivity are currently present, not including the area of the main channel. Under each Alternative, it is assumed that normal operations combined with tributary inflow

would result in floodplain connectivity of at least 77,410 acres as indicated by the mapping results described previously, thus no additional action would be required. This analysis should not be interpreted to indicate that floodplain connectivity has increased from 77,410 acres to 147,650 acres from 2003 to present. Only that current normal operations combined with tributary inflow are meeting numeric criteria for floodplain connectivity developed by USFWS in 2015.

Comments (Comment ID): 643028, 643034

Concern Statement: The Propagation and Augmentation Program for pallid sturgeon should be continued, but only with “pure” pallid sturgeon. The numbers stocked should be based on best available science and should be considered temporary.

Response: USACE and USFWS will continue to follow the propagation protocols developed by the pallid sturgeon working group and USFWS. Stocking is considered a temporary measure; the objectives of the management plan are directed at natural recruitment. Population augmentation is designed to ensure genetic diversity using local and wild broodstock collection (Pallid Sturgeon Recovery Team 2008).

Representative Quotes (Correspondence ID): 237
Comments (Comment ID): 643064

Concern Statement: The sustainability of available sediment to continue to construct new ESH over the 50-year life of the MRRP should be evaluated.

Response: Available information and analysis performed by USACE indicate that there is not a sand volume limitation for the formation of sandbars in the Gavins Point or Garrison Reach over the 50-year planning horizon for this project. This discussion is provided in Section 3.2 of the Final EIS.

Representative Quotes (Correspondence ID): 107
Comments (Comment ID): 643881

Concern Statement: SWH has not been developed to the level described in the No Action alternative. As such it is not a reference or base case and really represents impacts of the alternatives that have not been realized. Additionally, the impacts to thermal power, should not be compared to the impacts modelled for Alternative 1 in an incremental or comparative manner as done in the Draft EIS. The Draft EIS must present the NED and RED results for each alternative in a total and individual manner as is done in the Hydropower section. The comparison of impacts of Alternatives 2–6 to Alternative 1 as presented makes the impacts appear less than as currently described in Alternative 1.

Response: The No Action Alternative is a forecast of the program into the future assuming the 20 acres per mile SWH objective of the 2003 BiOp is achieved. USACE believes constructing habitat to meet existing acreage goals is a reasonable assumption for the No Action alternative. It is designed to estimate impacts in the future rather than impacts that have already been realized.

In addition, the thermal power NED analysis has been re-analyzed to show the power generated (and energy values) under each of the alternatives, not the reduction in power generation from ideal conditions with no adverse conditions as shown in the Draft EIS. The Final EIS has been updated to show the total impacts under each of the alternatives over the period of record, the average annual impacts, and the change in impacts from

No Action. The “Thermal Power Environmental Consequences Analysis Technical Report” shows additional details on annual impacts.

Comments (Comment ID): 643892

Concern Statement: USACE needs to provide a stronger commitment to the transition from Level 1 and Level 2 research activities to implementation of Level 3 actions. USACE should define and analyze the scope of Level 3 actions to remove ambiguity.

Response: USACE is committed to the adaptive management process as described in the SAMP. The adaptive management governance process details decision points, levels of engagement, and potential new hypotheses and associated management actions that could be implemented should science point in their direction in the future. The EIS describes level 3 actions where possible. In some instances, the available science does not provide a meaningful basis for determining what a level 3 action would entail.

Representative Quotes (Correspondence ID): 183
Comments (Comment ID): 643922

Concern Statement: The selected alternative should include a broad spectrum of potential management actions (including flow actions). A more thorough evaluation of when such actions might occur while minimizing impacts to stakeholder interests should also be undertaken.

Response: The evaluation associated with flow actions was based on the best available models and information. Actions outside of the preferred alternative, or selected alternative, are still available for implementation pending additional analysis and public involvement. USACE believes it has selected a reasonable set of initial actions to be implemented over a 15-year timeframe that address priority hypotheses and the species objectives. It would not be appropriate to include the myriad of potential actions in the selected alternative if it is not reasonably foreseeable that they would need to be implemented. The alternative is designed to give the public, Tribes, stakeholders, and other agencies reasonable expectations of what will be implemented rather than include a myriad of potential actions that may or may not be implemented. The AM process allows for new actions, not within the selected alternative, to be implemented following a transparent discourse with the Tribes, public, stakeholders, and other agencies.

Comments (Comment ID): 643930

Concern Statement: The location of proposed IRC habitat needs a thorough siting evaluation to avoid locations such as water intake structures.

Response: Concur, each site will be designed to avoid or minimize impacts to critical infrastructure such as water intakes.

Representative Quotes (Correspondence ID): 107
Comments (Comment ID): 643932

Concern Statement: USACE should reconsider management actions below Fort Peck Dam for the pallid sturgeon because research results indicate there is potential for survival/recruitment of larval sturgeon.

Response: USACE believes it has followed the best available science in relation to actions below Fort Peck Dam. In recognition of the scientific uncertainty surrounding Fort Peck flow adjustments, USACE agreed to formulate test flows from Fort Peck and an AM framework for their implementation during formal ESA Section 7 consultation on this plan. Studies under the framework may include additional drift studies, tracking of fish and documentation of spawning locations, telemetry evaluations and methodology improvements, risk analysis, and engineering studies. Implementation of an identified hydrograph to test hypotheses would be considered; however, depending on the specifics of the test hydrograph, may be outside the scope of this EIS.

Representative Quotes (Correspondence ID): 183
Comments (Comment ID): 643933

Concern Statement: The MRRMP process only delays implementation of needed management actions by requiring prior and often redundant research into the minutiae of already successful upper basin pallid sturgeon programs such as propagation and stocking.

Response: The Effects Analysis and SAMP were developed by a team of internationally recognized experts in sturgeon biology, tern and plover biology, population modeling, adaptive management, and other related fields. The Effects Analysis and SAMP have been thoroughly reviewed by an independent science advisory panel consisting of internationally recognized experts in the field. USACE and USFWS believe the Effects Analysis represents the best available science related to the three species. The SAMP is based on the results of the Effects Analysis and provides a process where hypotheses can be tested and the agencies can adjust as more is learned. Science and implementation activities are scheduled in detail in the plan to avoid delays in knowledge acquisition and implementation.

Representative Quotes (Correspondence ID): 191
Comments (Comment ID): 644019

Concern Statement: Any alternative that would cause a power plant to be shut down or de-rate as a result of a low flow should not be implemented.

Response: The preferred alternative does not include flow alterations that would involve shut downs or de-rating. It does include nine years of study of existing spring pulses from intervening tributary flows to better understand pallid sturgeon responses. Combined with existing data, we believe this will be sufficient to determine if a spring pulse is necessary.

Comments (Comment ID): 644080

Concern Statement: The impacts of the Yellowtail Dam on the thermograph, hydrograph, turbidity, and bedload of the Yellowstone River should not be ignored. References to near natural conditions on the Yellowstone should not be used.

Response: Concur, references to “near natural” have been removed for clarity.

Representative Quotes (Correspondence ID): 191
Comments (Comment ID): 644095

Concern Statement: Level 1 and Level 2 actions do not meet the definition of a management action and should not be presented as such.

Response: USACE and USFWS understand that Level 1 and Level 2 actions do not represent actions expected to have a population level response in the species. For this reason, we have included level 3 management actions in the preferred alternative despite uncertainties regarding their effectiveness. USACE believes that detailing Level 1 and Level 2 science activities will facilitate an organized and efficient means to answering key questions which will improve the effectiveness of implementation.

Representative Quotes (Correspondence ID): 191
Comments (Comment ID): 644101

Concern Statement: The Bozeman Fish and Technology Center is no longer producing pallid sturgeon for conservation stocking.

Response: Concur, the text has been modified as suggested.

Representative Quotes (Correspondence ID): 191
Comments (Comment ID): 644111

Concern Statement: A more complete description of channel widening and how will it benefit age-0 pallid sturgeon recruitment needs to be provided. Additionally, how SWH and IRCs differ should be explained (other than identifying interception, and rearing as the function of IRCs, as if these functions were not implied for SWH if age-0 pallid were to settle and survive there).

Response: A discussion about the differences between SWH and IRCs is provided in Section 4.2 of the SAMP and Section 2.6.3 of the EIS. In order to achieve the 20–30 acres of SWH per mile goal under Alternatives 1 and 2 it was determined that top-width widening would need to be the primary method of SWH construction into the future because there are not enough areas projected to be available to achieve those acreages if chute or backwater construction were used as the primary method. Channel widening was also assumed for impact analysis under Alternatives 3–6 because it is still uncertain what method exactly would be used to create IRCs in every instance under Alternatives 3–6. The NEPA analysis assumed channel widening to display the impacts that *could* result under an all top-width widening scenario. Since release of the Draft EIS it has been determined that much of the initially required IRC habitat can be created through river structure modifications which is a less costly means of achieving IRC habitat than top-width widening. However, it is anticipated that at least some IRC habitat will need to be achieved through top-width widening in the future because eventually all the areas with a high likelihood of success via structure modifications will be used. The projected costs for Alternatives 3–6 have been updated for the Final EIS. During implementation, the most effective and efficient means to construct IRC habitat will be used. In some cases that could be modifications to a dike structure to increase interception. In other cases that could entail top-width widening to create additional foraging and feeding habitat along with interception. In the SAMP we have outlined a detailed transparent process that will occur during implementation as sites and construction methods are being determined.

Representative Quotes (Correspondence ID): 245
Comments (Comment ID): 644909

Concern Statement: An explanation should be provided as to why channel widening has become the proposed management action of choice for all Draft EIS early life history habitat construction alternatives when there is limited scientific evidence to support any benefits to pallid sturgeon recruitment.

Response: A discussion about the differences between SWH and IRCs is provided in Section 4.2 of the SAMP and Section 2.6.3 of the EIS. In order to achieve the 20–30 acres of SWH per mile goal under Alternatives 1 and 2 it was determined that top-width widening would need to be the primary method of SWH construction into the future because there are not enough areas projected to be available to achieve those acreages if chute or backwater construction were used as the primary method. Channel widening was also assumed for impact analysis under Alternatives 3–6 because it is still uncertain what method exactly would be used to create IRCs in every instance under Alternatives 3–6. The NEPA analysis assumed channel widening to display the impacts that **could** result under an all top-width widening scenario. Since release of the Draft EIS it has been determined that much of the initially required IRC habitat can be created through river structure modifications which is a less costly means of achieving IRC habitat than top-width widening. However, it is anticipated that at least some IRC habitat will need to be achieved through top-width widening in the future because eventually all the areas with a high likelihood of success via structure modifications will be used. The projected costs for Alternatives 3–6 have been updated for the Final EIS. During implementation, the most effective and efficient means to construct IRC habitat will be used. In some cases that could be modifications to a dike structure to increase interception. In the SAMP we have outlined a detailed transparent process that will occur during implementation as sites and construction methods are being determined.

Representative Quotes (Correspondence ID): 245
Comments (Comment ID): 644910

Concern Statement: There is limited scientific evidence to support the stated benefits of channel widening to support recruitment of age-0 pallid sturgeon. USACE should clarify why channel widening appears as the primary management action to create SWH. What alternative hypotheses (under an active AM approach) were considered to create pallid sturgeon early life history habitat and the science to support them? Revise proposed management actions and associated costs for SWH construction for the No Action and BiOp alternatives to reflect historical actions employed and actual costs used to create SWH, or justify why the proposed No Action and BiOp alternatives SWH proposed costs to continue the existing program have escalated so much. Revise proposed costs for IRC construction via channel widening for Alternatives 3–6 to be in line with observed costs to create the three identified IRCs or justify why proposed costs for any additional IRCs have escalated so much.

Response: A discussion about the differences between SWH and IRCs is provided in Section 4.2 of the SAMP and Section 2.6.3 of the EIS. In order to achieve the 20–30 acres of SWH per mile goal under Alternatives 1 and 2 it was determined that top-width widening would need to be the primary method of SWH construction into the future because there are not enough areas projected to be available to achieve those acreages if chute or backwater construction were used as the primary method. Channel widening was also assumed for impact analysis under Alternatives 3–6 because it is still uncertain what method exactly would be used to create IRCs in every instance under Alternatives 3–6. The NEPA analysis assumed channel widening to display the impacts that **could** result under an all top-width widening scenario. Since release of the Draft EIS it has been determined that much of the initially required IRC habitat can be created through river structure modifications which is a less costly means of achieving IRC habitat than top-width widening. However, it is anticipated that at least some IRC habitat will need to be

achieved through top-width widening in the future because eventually all the areas with a high likelihood of success via structure modifications will be used. The projected costs for Alternatives 3–6 have been updated for the Final EIS. During implementation, the most effective and efficient means to construct IRC habitat will be used. In some cases that could be modifications to a dike structure to increase interception. In other cases that could entail top-width widening to create additional foraging and feeding habitat along with interception. In the SAMP we have outlined a detailed transparent process that will occur during implementation as sites and construction methods are being determined.

Representative Quotes (Correspondence ID): 245
Comments (Comment ID): 644915

Concern Statement: The differences in mechanical emergent sandbar habitat construction conveyed in the Draft EIS for alternatives are unreasonable. USACE does nothing more than intimate that the flow releases of Alternatives 3–6 may bridge the gaps in ESH between Alternative 2 and the other alternatives by creating sandbar habitat through sediment deposition. USACE should provide an estimate of sandbar habitat that might be created through flow releases.

Response: The ESH targets in Alternatives 1 and 2 are based on the 2003 Biological Opinion and are a projection of what would occur if current acreage targets are followed. ESH acreages under Alternatives 3–6 are what would be needed to achieve the new ESH targets developed by USFWS. The “gap” in ESH acreages between Alternatives 1 and 2 and Alternatives 3–6 reflect the difference between the ESH targets in the 2003 BiOp and the ESH targets generated using a newer modeling approach. Both sets of targets were given to USACE by USFWS. It is important to understand that the ESH acreage targets represent a means to achieving the fundamental objective which is measured in terms of bird response. The intent is to provide a comparison, in terms of bird response, between using the ESH targets from the 2003 BiOp vs. the newer targets that are now reflected in the 2018 BiOp. This is consistent with the requirement under NEPA to examine the No Action alternative to measure the benefits of newer courses of action vs. current courses of action. It is also important to understand that under Alternatives 4, 5, and 6 flows were first modeled to determine how much habitat could be created via flows. It was then assumed the shortfall in acres under these alternatives would be constructed mechanically. The modeled estimates of ESH that could be created with flows under Alternatives 4 and 5 (the two alternatives with flows designed to create ESH) has been added to the Final EIS in Section 3.4. The ESH acres under Alternatives 3–6 meet the piping plover objectives. There is no need at this point to look for ESH acreages that fall in-between Alternative 2 and Alternatives 3–6.

Comments (Comment ID): 644943, 644944

Concern Statement: Tables 2-20 and 2-21 of the Draft EIS use different labels for some of the units displayed, yet the numbers stay the same confusing the reader. For example, Table 2-20 has a column with the heading "Target Acres of Channel Widening." Table 2-21 uses those same values in a column headed "Target Acres of SWH." This creates confusion over the meaning of the acreage numbers and makes it challenging to assess the validity of the range of alternatives based on the early life stage habitat management actions.

Response: A discussion about the differences between SWH and IRCs is provided in Section 4.2 of the SAMP and Section 2.6.3 of the EIS. Alternatives 1 and 2 SWH acreages are based on the low and high ends of SWH acreage targets in the 2003 BiOp. The IRC habitat targets and acre/day metrics represent what it would take to meet IRC targets recently established by USFWS. The Final Biological Assessment and Final EIS also include additional IRC habitat that could be required if level 4 implementation is determined to be different than level 3 implementation in the future.

Representative Quotes (Correspondence ID): 223
Comments (Comment ID): 644946

Concern Statement: The Draft EIS does not sufficiently discuss the differences between SWH and IRC. Because of stated differences, SWH and IRC should not be considered as comparable or interchangeable techniques for habitat creation. Additionally, the Draft EIS does not specify what would happen if the results of the research on IRC demonstrates that it does not benefit the pallid sturgeon.

Response: A discussion about the differences between SWH and IRCs is provided in Section 4.2 of the SAMP and Section 2.6.3 of the EIS. The Final EIS and SAMP describe the decision criteria and process that will be used to determine if IRC is effective. The same process outlines the process that will be followed to determine the next priority hypotheses that would need to be examined and what the associated actions could be.

Representative Quotes (Correspondence ID): 223
Comments (Comment ID): 644947

Concern Statement: Alternatives 3–6 should include varying levels of floodplain connectivity to ensure beneficial impacts to the pallid sturgeon.

Response: Best available science does not indicate that pallid sturgeon are food limited at any life stage or that additional floodplain connectivity is needed to support any other life-stage requirements for pallid sturgeon. USACE coordinated with USFWS during development of Alternative 2 to identify criteria for clarification of the floodplain connectivity language from the 2003 BiOp. The 2003 BiOp did not contain numeric criteria for floodplain connectivity. USFWS provided these criteria in a Planning Aid Letter submitted to USACE on November 5, 2015. The criteria stated that the management action should maximize floodplain habitat by ensuring that 77,410 acres of connected floodplain are inundated at a 20 percent annual chance exceedance. This acreage amount was an interpretation, made in 2015, of the language from the 2003 BiOp developed to inform alternatives development. USACE conducted HEC-GeoRAS mapping to determine the acres of existing floodplain connectivity in the lower Missouri River. This was the first time this type of an analysis had been done. The mapping results indicated that 147,650 acres of floodplain connectivity are currently present, not including the area of the main channel. Under each Alternative, it is assumed that normal operations combined with tributary inflow would result in floodplain connectivity of at least 77,410 acres as indicated by the mapping results described previously, thus no additional action would be required. This analysis should not be interpreted to indicate that floodplain connectivity has increased from 77,410 acres to 147,650 acres from 2003 to present. Only that current normal operations combined with tributary inflow are meeting numeric criteria for floodplain connectivity developed by USFWS in 2015.

Representative Quotes (Correspondence ID): 179, 223
Comments (Comment ID): 644954, 645208

Concern Statement: The implementation of IRC habitat should be accelerated; beginning with the assessment of the first pair that are constructed.

Response: Construction of IRC habitat will begin immediately with plans for the first sites already in development. Sites would be constructed over the first 7 years and if determined to be effective they would continue to be constructed throughout the 15-year implementation horizon of the plan.

Representative Quotes (Correspondence ID): 42, 179
Comments (Comment ID): 645241, 628511

Concern Statement: The proposed flow modifications would not only benefit the pallid sturgeon but also the entire the fish community. USACE should (1) assess the likelihood that they will implement each alternative, (2) establish a set of criteria that would place the needs of pallid sturgeon on equal footing with downstream water users, and (3) establish a set of performance criteria that would ensure accountability with the selected alternative.

Response: USACE has identified its preferred alternative along with decision criteria and a decision process that will be used to determine effectiveness and determine if we will stop, continue, or adjust actions in the future. USACE considered a full range of reasonable alternatives designed to meet the endangered species objectives and compared the impacts of these different alternatives in terms of resources described in the Affected Environment and Environmental Consequences. Section 2.9 of the Final EIS provides a clear comparison of alternatives in terms of the species objectives, Affected Environment and Environmental Consequences and provides a description of how those factors were weighed in the decision. USACE believes it has selected the alternative that is least impactful across the full range of interests while still meeting species objectives. USACE believes it has taken the full spectrum of considerations into account in the decision-making process and this is well-documented in the Final EIS and supporting materials.

Representative Quotes (Correspondence ID): 238
Comments (Comment ID): 645324

Concern Statement: The proposed frequency of enhanced flows is not supported by scientific evidence and is likely insufficient for pallid sturgeon recovery. If evidence does exist, USACE should include this within the EIS.

Response: Rather than a comparison to historical pre-dam and pre-bank stabilization conditions, USACE believes the science and adaptive management approach that consists of research, monitoring of natural flow events, and potential test flows is more likely to be successful given the extensive modifications to the Missouri River to support authorized purposes. The flows for ESH creation are scientifically supported. We have a population model that predicts the response of terns and plovers to different ESH creating flow events and those results are provided in the EIS.

Representative Quotes (Correspondence ID): 238
Comments (Comment ID): 645333

Concern Statement: The Draft EIS and supporting documents are not clear why tracking standardized ESH is necessary. If the "standard" release does not occur in a given year, it is not clear how standardized ESH is determined if it is not measured.

Response: Clarification has been added to Chapter 1 of the EIS. The value of the standardized approach is that it allows estimates of ESH acreage relative to a consistent reference

plane and permits tracking of changes in overall sandbar area independent of variable flow levels. Acres of ESH are calculated using the ESH Models for each reach and confirmed annually using remotely sensed imagery and the HEC-RAS models.

Representative Quotes (Correspondence ID): 239
Comments (Comment ID): 645359

Concern Statement: Scientific evidence is presented suggesting that a change in conditions other than high-magnitude flooding is required to return the Missouri River to its pre-dam condition, or restore the ecosystem to a self-maintaining state.

Response: The preferred alternative does not include flow alternations that would impact the Garrison Reach. It does include nine years of study of existing spring pulses from intervening tributary flows to better understand pallid responses. Combined with existing data, we believe this will be sufficient to determine if a spring pulse from Gavins Point Dam is necessary. Available information and analysis performed by USACE indicate that there is not a sand volume limitation for the formation of sandbars in the Garrison Reach over the 50-year planning horizon for this project.

Representative Quotes (Correspondence ID): 239
Comments (Comment ID): 645366

Concern Statement: The Draft EIS needs to explain the cost versus benefits of constructing ESH. There are benefits to mechanical created habitat as it relates to vegetation removal from existing ESH for the free-flowing stretches of the Garrison Reach. If mechanical creation is required, it is recommended this occur only in the aggrading reaches and in the Lake Oahe delta.

Response: USACE agrees that vegetation removal can be a viable cost-effective way to create and/or maintain ESH; however, it may be necessary to mechanically construct ESH to meet targets in some years. In the future, USACE and USFWS will coordinate and consult with the ESH PDT including the State of North Dakota in planning and implementing site specific ESH projects. Concerns related to bar location, longevity, property owner concerns, and regulatory agency input would be a key part of these discussions. The ESH engagement process is explained in the SAMP.

Representative Quotes (Correspondence ID): 239
Comments (Comment ID): 645367

Concern Statement: Reduced flow can potentially increase the rate of erosion as the reduced flows will likely result in higher flows later in the year to evacuate flood storage in the reservoirs.

Response: Concur, clarification has been added to Section 2.5.1.9 of the Final EIS.

Representative Quotes (Correspondence ID): 239
Comments (Comment ID): 645369

Concern Statement: The State of North Dakota is not supportive of restricting human access to sandbars in areas of high human use, such as the Missouri River in the Bismarck Mandan area.

Response: Areas of high-human use are less likely to have nesting plovers and terns and are not anticipated to be restricted.

Representative Quotes (Correspondence ID): 239
Comments (Comment ID): 645370

Concern Statement: Flows for any alternative should be managed to be at or below the stated channel capacity, unless impacts are mitigated.

Response: The preferred alternative does not include flow alterations that would impact the Garrison Reach. It does include nine years of study of existing spring pulses from intervening tributary flows to better understand pallid responses. Combined with existing data, we believe this will be sufficient to determine if a spring pulse from Gavins Point Dam is necessary. NEPA requires the analysis of a reasonable range of alternatives to meet the purpose and need including alternative that may be outside the current authorities of the agency.

Representative Quotes (Correspondence ID): 239
Comments (Comment ID): 645387

Concern Statement: Vegetation management is the preferred method for meeting targets for habitat acreages for piping plovers and least terns. It is recommended that USACE maintain the agreed upon moratorium of management actions in the Bismarck-Mandan area. Additionally, it is necessary to maintain a buffer one mile around boat ramps with the same restrictions.

Response: USACE agrees that vegetation removal can be a viable cost-effective way to create and/or maintain ESH; however, it may be necessary to mechanically construct ESH to meet targets in some years. USACE will continue to work with the interagency ESH Team on any site restrictions to avoid human/bird conflicts.

Representative Quotes (Correspondence ID): 239
Comments (Comment ID): 645399

Concern Statement: The MRRMP-EIS includes spawning cue releases as a management action without adequately explaining their effects and without adequate knowledge of what the specific beneficial impacts of the actions would be on the pallid sturgeon. The spawning cue should be analyzed over time while other management actions are being used to meet the species goals until the spawning cue release is established as a viable management action.

Response: The preferred alternative follows the suggested approach of analyzing the spawning cue over time while implementing other management actions. It is true that effects of the spawning cue pulse are uncertain; however, the spawning cue pulse emerged as a priority hypothesis to investigate from an independent group of scientists as explained in the pallid sturgeon effects analysis reports and the SAMP.

Representative Quotes (Correspondence ID): 240
Comments (Comment ID): 645417

Concern Statement: The Final EIS needs to address how long long-term monitoring at Intake would continue before AM is implemented to make the needed adjustments to ensure successful pallid recruitment.

Response: Monitoring for the Yellowstone Intake project is addressed in the Monitoring and Adaptive Management Plan for the Yellowstone Intake Project. The Monitoring and AM Plan is provided as Appendix E to the Yellowstone Intake EIS at: <https://www.usbr.gov/gp/mtao/loweryellowstone/>

Representative Quotes (Correspondence ID): 242
Comments (Comment ID): 645530

Concern Statement: USACE places too much emphasis on hatchery raised pallid sturgeon as stocking creates a population that is not self-sustaining. Concern is also expressed about the cost of hatchery raised fish and the potential for introduction of disease. More emphasis should be placed on habitat restoration to support pallid recovery.

Response: There is no evidence that stocking leads to a non-self-sustaining population. Contrary to this theory, pallid sturgeon stocked early in the program are just recently reaching sexual maturity and there is documented evidence of stocked pallid sturgeon growing, spawning, and producing viable drifting embryos. A Pallid Sturgeon Basin-wide Stocking and Augmentation Plan is being developed by the Pallid Sturgeon Recovery Team and participating federal agencies due to concerns related to fish health/disease, genetics, stocking size, numbers/carrying capacity, stocking practices etc. It should be noted that the hatchery program is led by USFWS. USACE has a role in partially funding the program and providing technical input. The cost of the propagation program is much less expensive than habitat restoration.

Representative Quotes (Correspondence ID): 242
Comments (Comment ID): 645535

Concern Statement: The EIS should provide more detail about the flood risk associated with Level 2 field experiments.

Response: Field experimentation could include flow manipulations or channel reconfigurations that would involve risk of impacts to various interests. These are explained in the EIS in relation to the one-time test flow that could occur as a level 2 action. Continued engagement and communication with stakeholders will continue throughout the AM process.

Representative Quotes (Correspondence ID): 242
Comments (Comment ID): 645583

Concern Statement: Opposition is expressed for Alternatives 2, 4, 5, and 6 or any management actions that would modify flows of the river and require a change to the Master Manual.

Response: The preferred alternative includes nine years of study of existing spring pulses from intervening tributary flows to better understand pallid responses. Combined with existing data, we believe this will be sufficient to determine if a spring pulse from Gavins Point Dam is necessary.

Representative Quotes (Correspondence ID): 176
Comments (Comment ID): 645775

Concern Statement: In addition to Level 1 and Level 2 research, Level 3 and Level 4 actions need to be implemented in a manner that results in population level changes.

Response: The preferred alternative involves implementation of actions designed to have population level changes simultaneously to conducting level 1 and 2 research. Given the uncertainty in the nature of management actions needed for pallid sturgeon USACE believes it is important to invest resources in Level 1 and 2 research to inform future level 3 and 4 actions. The alternative would be to implement potentially costly, ineffective large-scale management actions that could have unintended consequences.

Representative Quotes (Correspondence ID): 238
Comments (Comment ID): 645836

Concern Statement: Management actions should be implemented below Fort Peck to protect the source population of pallid sturgeon.

Response: Modifications at Fort Peck Dam were considered during alternatives formulation. Please see Section 2.5.21 of the Final EIS for a detailed discussion of the status of actions at Fort Peck Dam. In recognition of the scientific uncertainty surrounding Fort Peck flow adjustments, USACE agreed to formulate test flows from Fort Peck and an AM framework for their implementation during formal ESA Section 7 consultation on this plan. Studies under the framework may include additional drift studies, tracking of fish and documentation of spawning locations, telemetry evaluations and methodology improvements, risk analysis, and engineering studies. Implementation of an identified hydrograph to test hypotheses would be considered; however, depending on the specifics of the test hydrograph, may be outside the scope of this EIS.

Representative Quotes (Correspondence ID): 238
Comments (Comment ID): 645838

Concern Statement: USACE should not count rehabilitating SWH as new IRC habitat because this appears to be using already created habitat to count as new habitat.

Response: USACE has expended substantial resources in building shallow water habitat over the past 14 years. USACE believes it is a reasonable expenditure of program funding to make existing channel modification projects more effective, for instance, by improving the probability of interception or expanding the area meeting the definition of food producing or foraging habitat. The new objectives developed by USFWS are species driven. Success ultimately depends on species response rather than acres of habitat that may or may not be effective at meeting species needs.

Representative Quotes (Correspondence ID): 238
Comments (Comment ID): 645792

Concern Statement: Any alternative considered with low summer flows may create river conditions with high temperatures and low turbidity favorable for cyanotoxins growth requiring more extensive treatment than is currently required.

Response: The preferred alternative includes nine years of study of existing spring pulses from intervening tributary flows to better understand pallid responses. Combined with existing data, we believe this will be sufficient to determine if a spring pulse from Gavins Point Dam is necessary.

Representative Quotes (Correspondence ID): 204
Comments (Comment ID): 645749

Concern Statement: The comparison of alternatives chart included with the Executive Summary uses different metrics for different resources making any comparison by members of the public challenging.

Response: The summary table in the Final EIS is consistent with the text in Chapters 2 and 3 of the EIS. The summary table in the Draft EIS was also consistent with the text in Chapter 3 of the EIS, but did contain generalized information which was intended as a convenience for the reader. It was not meant to be used in place of the full analysis in

the body of Chapter 3 of the EIS as explained in the introductory text for the table contained in the Executive Summary of the Draft EIS:

“The following table provides a summary comparison of the general environmental consequences of each action alternative compared to Alternative 1—the No Action alternative—in terms of being beneficial or adverse. The impacts of the No Action Alternative and the Action Alternatives are provided in-detail under each resource topic in Chapter 3-Affected Environment and Environmental Consequences.”

Additional language was presented in Chapter 2 of the Draft EIS: “Average annual numbers present an important but incomplete perspective on the impacts of the alternatives...For this reason, it is important to understand the year-by-year impacts of each alternative, and these are discussed in detail in Chapter 3 and further described in a series of technical reports available at www.moriverrecovery.org. In this Summary discussion, only the most sensitive cases of this effect are noted. See Chapter 3 for a full analysis of the resources evaluated in this MRRMP-EIS.”

USACE believes the summary tables are a useful means of summarizing complicated information. Summary tables are included in the Final EIS and reflect updates made since release of the Draft EIS.

Comments (Comment ID): 640186

Concern Statement: Support is expressed for use of the new SAMP and a suggestion made that the most critical information needs should be emphasized in future monitoring.

Response: Concur, USACE intends to follow the new AM approach outlined in the SAMP.

Representative Quotes (Correspondence ID): 237
Comments (Comment ID): 643036

Concern Statement: USACE should provide the regulatory strategy for IRCs; otherwise the economics presented in the Draft EIS are incomplete.

Response: The regulatory strategy for IRCs will be determined by the actual Regulatory process; however, the Final EIS estimates the potential impacts from future protective buffers that could be placed on commercial sand and gravel dredging in the vicinity of Interception Rearing Complex (IRC) projects (Section 3.11 of the Final EIS). This analysis does not create a restriction, it does however project what impacts could be in the future if restrictions result from the Regulatory process.

Representative Quotes (Correspondence ID): 222
Comments (Comment ID): 644790

Concern Statement: Off-channel nesting habitat for the piping plover outside the active river channel should be included with each alternative.

Response: As explained in Section 2.5.1.4 of the Draft EIS, USFWS recommended that USACE not include sandpit habitat management or habitat development in the navigation channel as management actions in this plan (USFWS 2015a). USFWS identified several issues that would need to be resolved to consider this a feasible management action including the reproductive potential of these areas, potential for high predation, habitat preferences and dispersal, forage availability, land acquisition, and feasibility of creation and maintenance (USFWS 2015a). This management action was eliminated from further consideration because it is not currently demonstrated to be as

effective or efficient at meeting species objectives relative to other available management actions such as in-river construction of ESH and vegetation management on ESH (USACE 2012a). Although this action was eliminated from consideration in this EIS, USFWS has been working with MRRIC to pursue a pilot project with alternate funding (not through MRRP). The results of the pilot project could be evaluated through the AM process and incorporated into future management if deemed effective.

Comments (Comment ID): 645777

Concern Statement: Nebraska Game and Parks Commission believes that the habitat goal of 20 to 30 acres of aquatic habitat per mile remains the most fundamental means to address the critical needs of pallid sturgeon and the native fish community upon which they depend. Rather than just building habitat of general design, this effort could be greatly improved by targeting specific habitat needs for both pallid sturgeon and the native fish community.

Response: The new objectives developed by USFWS are species driven. Success ultimately depends on species response rather than acres of habitat that may or may not be effective at meeting species needs. The approach in the preferred alternative includes constructing 12 IRC sites to determine effectiveness and increasing the number of sites if they are determined to be effective. The cornerstone of this approach is the development of a thoughtful structured approach to management, monitoring and assessment where management actions with uncertain benefits are approached as methods to be tested prior to large expenditures of money and resources for very uncertain benefits.

Representative Quotes (Correspondence ID): 237
Comments (Comment ID): 643113

Concern Statement: The implementation and viability of proposed alternatives is questioned because USACE to date has not successfully implemented changes in reservoir operations to support pallid sturgeon recovery.

Response: The alternatives development process and subsequent evaluation of effect on pallid sturgeon was based on the Effects Analysis results. The EIS provides a detailed accounting of the impacts of the alternatives including viability and consequences of implementation in Chapters 2 and 3. The Draft EIS recognizes the substantial uncertainty that remains relative to cause and effect relationships between managed flow actions and pallid sturgeon populations. Adaptive management was included as a component of all alternatives evaluated in the Draft EIS due to the need to implement actions for pallid sturgeon in a manner that reduces uncertainty regarding pallid sturgeon limiting factors.

Comments (Comment ID): 645327

AL100 *Alternatives: Alternative 1, No Action*

Concern Statement: There is opposition to Alternative 1 as it still allows for a bi-modal spring rise and shallow water habitat without the science to suggest its effectiveness.

Response: Comment noted. Alternative 1 was not identified as the preferred alternative. The inclusion of a no action alternative is required by 40 CFR 1502.14(d). There are two

interpretations of "no action," depending on the nature of the proposal being evaluated. One interpretation reflects "no change" from current management direction or level of management intensity. Under the No Action alternative, the MRRP would continue to be implemented as it is currently.

Representative Quotes (Correspondence ID): 28, 33, 98, 197, 204, 228

Comments (Comment ID): 627555, 633683, 645248, 645450, 644448, 627997

Concern Statement: Alternative 1 does not serve as a baseline or reference case or meet the NEPA definitions of the No Action alternative as:

- ISAP has found the spring pulse management action does not benefit pallid sturgeon and SWH development does not provide benefit to pallid sturgeon;
- it is a major change from the current level of management intensity as it includes additional actions; and
- it describes the actions USACE would do, or would like to have done, if only it had been given the resources to comply with the existing 2003 amended biological opinion, and the Reasonable and Prudent Actions (RPAs) from the 2000 biological opinion.

Response: The No Action alternative is a reasonable reference case and meets the intent of including a No Action alternative in the planning process. It should be noted that the 2003 BiOp was developed before the recent effects analysis. To assume Alternatives 1 or 2 would follow the effects analysis results and new SAMP would not provide a useful comparison because we would be comparing Alternatives 3–6 to 2003 BiOp alternatives that assume the existence of the very alternative plans being proposed.

Representative Quotes (Correspondence ID): 107, 166, 245

Comments (Comment ID): 643781, 644907, 644922

Concern Statement: It is disingenuous to assert that Alternative 1 does not meet the needs of the birds when the only justification provided in the EIS for that assertion is that Alternative 1 includes an annual average of 107 acres of mechanical ESH construction. The 107 acres of ESH construction under Alternative 1 does not include the acres gained due to vegetation maintenance and misrepresents and underestimates the actions that are currently being implemented.

Response: Alternative 1 acres have been adjusted from the Draft EIS to 164 acres constructed per year on average. This amount is consistent with the selected alternative from the 2011 Programmatic EIS for the Creation of Emergent Sandbar Habitat. Even with the added acreage the modeling results still show Alternative 1 falling short of ESH targets in the southern bird management region. During implementation, acres of ESH maintained from vegetation management would be included in the annual ESH estimates that are used to determine if construction is needed. One priority for improving the ESH model during implementation is to develop the capability to more accurately predict the response of ESH to vegetation management.

Representative Quotes (Correspondence ID): 239

Comments (Comment ID): 645379

AL200 **Alternatives: Alternative 2**

Concern Statement: The low summer flows under Alternative 2 are opposed. They have not been proven to be a beneficial management action for pallid sturgeon. Additionally, the MRRMP-EIS states that low summer flows would only be infrequently implemented. This management action is unnatural as it would not mimic the timing of lower flows as compared to the pre-settlement hydrograph and it would cause economic and environmental harm. The Draft EIS failed to evaluate impacts and cost associated with Alternative 2 low summer flows on water supply intakes. The impacts of low summer flows on navigation would cause severe harm and would also impact sand and gravel dredging and thermal power. Alternative 2 relies on the USFWS 2003 Biological Opinion which lack scientific basis and is deeply flawed.

Response: The low summer flow in Alternative 2 was part of the 2003 Biological Opinion and was analyzed to determine the benefit to the species and impacts to other interests. Alternative 2 was not identified as the preferred alternative, in part, because of the estimated impacts to other river uses including support for authorized purposes such as water supply and navigation coupled with uncertain benefits for the species. The preferred alternative includes nine years of study of existing spring pulses from intervening tributary flows to better understand pallid responses. Combined with existing data, it is possible this will be sufficient to determine if a spring pulse is necessary and the one-time test may not be needed.

Representative Quotes (Correspondence ID): 37, 118, 130, 159, 168, 173, 187, 195, 197, 228, 240

Comments (Comment ID): 628462, 645613, 645452, 645418, 645266, 645252, 641557, 641000, 633811, 633750, 642102

Concern Statement: Alternative 2 is the best alternative because it allows habitat acres to be acquired and moves toward a more natural river that will sustain wildlife and provide a more secure future for endangered species. Additionally, Alternative 2 is the only alternative that links the MRRMP-EIS to the Bank Stabilization and Navigation (BSNP) Mitigation Project. The alternative also results in the fewest visual and recreational impacts. However, the number of mechanically created habitat acres should be reduced to lower the cost and the MRRMP-EIS should use the most scientifically advanced and proactive plan for adaptive management.

Response: The new objectives developed by USFWS are species driven. Success ultimately depends on species response rather than acres of habitat that may or may not be effective at meeting species needs. The Bank Stabilization and Navigation Mitigation Project is linked to every alternative in the Management Plan. It is the authority that would be used to purchase land from willing sellers and develop habitat under each alternative as explained in the EIS. The acres of constructed habitat in Alternative 2 follow the acreage targets for ESH and SWH provided in the 2003 Biological Opinion. The assumptions for Alternative 2 were provided by USFWS and documented via planning aid letter (USFWS 2015). For transparency, this planning aid letter was also shared with MRRIC at the same time it was shared with USACE. USACE believes the most scientifically advanced and proactive plan for adaptive management is the plan developed using the results of the recent effects analysis. The 2003 BiOp was developed before the recent effects analysis. To assume Alternatives 1 or 2 would follow the effects analysis results and new SAMP would result in a meaningless comparison

because we would be comparing newly proposed alternatives to 2003 BiOp alternatives that assume the existence of the new alternative plans being proposed.

Representative Quotes (Correspondence ID): 48, 63, 77, 78, 131, 141, 163, 166, 178, 179, 180, 183, 237

Comments (Comment ID): 633627, 628592, 636783, 640074, 640139, 641272, 641426, 642853, 643069, 643947, 644927, 637298, 641436, 641444, 645200

Concern Statement: Sufficient science has not been shown to support the benefits of a bimodal spring rise considered in Alternative 2.

Response: The preferred alternative includes nine years of study of existing spring pulses from intervening tributary flows to better understand pallid responses. Combined with existing data, it is possible this will be sufficient to determine if a spring pulse is necessary and the one-time test may not be needed.

Representative Quotes (Correspondence ID): 98, 145, 228

Comments (Comment ID): 633683, 637626, 645450

Concern Statement: Alternative 2 provides the best option for recovery of species. However, the implementation of some of the management actions included under Alternative 2 as the 2003 Biological Opinion is distorted. The MRRMP-EIS clearly states that new research and approaches developed since 2003 provide additional advantages in achieving recovery. Yet the MRRMP-EIS developed Alternative 2 excluding that interpretation of adaptive management. Only Alternative 2 and the No Action alternative exclude it. Thus, the MRRMP-EIS includes an alternative that up front does not meet its stated need for the plan.

Response: As stated in the EIS, the Purpose of the Plan is to develop a suite of actions that meets ESA responsibilities for the piping plover, the interior least tern, and the pallid sturgeon. The plan is needed because of alteration of the ecosystem and loss of habitats due to USACE operation of the System and BSNP have contributed to the ESA listing of the pallid sturgeon, piping plover, and interior least tern. There is also a need to incorporate new scientific information into management for the listed species. Ultimately, meeting the species objectives are the means for accomplishing the purpose and need of the project and all of the alternatives are designed to meet the species objectives. It is true that Alternatives 1 and 2 partially fulfill the need for the plan, but this does not free USACE from examining these alternatives in detail to determine if they would better achieve other aspects of the need, the purpose, objectives, or have less impacts or more benefits to other resources that are under consideration. It should be noted that the 2003 BiOp was developed before the recent effects analysis. To assume Alternatives 1 or 2 would follow the effects analysis results and new SAMP would not provide a useful comparison because we would be comparing Alternatives 3–6 to 2003 BiOp alternatives that assume the existence of the new alternative plans being proposed.

Representative Quotes (Correspondence ID): 131

Comments (Comment ID): 640122

Concern Statement: The difference between the acres of ESH constructed annually under Alternative 2 and the acres constructed annually under Alternative 3 is huge. This vast range of habitat acres and incomplete analysis fails to provide the public with a reasonable and understandable choice of alternatives. This amount of annual construction is neither warranted nor feasible and would cause major impacts on the remaining actions under Alternative 2 due to the high cost of these construction activities

and anticipated USACE MRRP budget limitations. Furthermore, the creation of this large number of acres per year would require creation of ESH in what is described as the exclusionary areas.

Response: The acres of constructed habitat in Alternative 2 follow the acreage targets for ESH and SWH provided in the 2003 Biological Opinion. The assumptions for Alternative 2 were provided by USFWS and documented via planning aid letter (USFWS 2015). For transparency, this planning aid letter was also shared with MRRIC at the same time it was shared with USACE. Since release of the Draft EIS, the acres under Alternative 2 were adjusted to be consistent with an updated analysis of ESH targets that were required by the 2003 BiOp. The updated acres result from a more-detailed analysis of acres that were present on the system in 1998 which was what the 2003 BiOp targets were based upon.

Comments (Comment ID): 640127, 641200, 642993, 645210, 645211, 645213

Concern Statement: The interpretation presented in the Draft MRRMP-EIS of shallow water habitat as an uncertain benefit is like stating that IRC and spawning habitat creation are experimental.

Response: There is uncertainty associated with both SWH and IRCs. The IRC concept is rooted in the effects analysis, however, which represents the best available science at this time.

Representative Quotes (Correspondence ID): 131

Comments (Comment ID): 640128

Concern Statement: While Alternative 2 would have broad benefits, it is described as meeting the minimum requirements of floodplain connectivity and inundation recommended.

Response: USACE coordinated with USFWS during development of Alternative 2 to identify criteria for clarification of the floodplain connectivity language from the 2003 BiOp. The 2003 BiOp did not contain numeric criteria for floodplain connectivity. USFWS provided these criteria in a Planning Aid Letter submitted to USACE on November 5, 2015. The criteria stated that the management action should maximize floodplain habitat by ensuring that 77,410 acres of connected floodplain are inundated at a 20 percent annual chance exceedance. This acreage amount was an interpretation, made in 2015, of the language from the 2003 BiOp developed to inform alternatives development. USACE conducted HEC-GeoRAS mapping to determine the acres of existing floodplain connectivity in the lower Missouri River. This was the first time this type of an analysis had been done. The mapping results indicated that 147,650 acres of floodplain connectivity are currently present, not including the area of the main channel. Under each Alternative, it is assumed that normal operations combined with tributary inflow would result in floodplain connectivity of at least 77,410 acres as indicated by the mapping results described previously, thus no additional action would be required. This analysis should not be interpreted to indicate that floodplain connectivity has increased from 77,410 acres to 147,650 acres from 2003 to present. Only that current normal operations combined with tributary inflow are meeting numeric criteria for floodplain connectivity developed by USFWS in 2015.

Representative Quotes (Correspondence ID): 131

Comments (Comment ID): 640129

Concern Statement: USFWS provided two sub-objectives to meet the fundamental objective of not jeopardizing the continued existence of the pallid sturgeon from USACE actions that stress the recruitment of young sturgeons. Both of these objectives are dependent on habitat construction, but a river flow management plan to fulfill the objective of natural recruitment has not been proven effective for implementation in Alternative 2. Alternative 2 proposes the continuation of a spring spawning cue pulse and low summer flows. The spawning cue has proven to be ineffective and the low summer flows are speculative actions.

Response: USFWS objectives provided for pallid sturgeon are focused on species response. In addition to habitat construction the preferred alternative includes nine years of study of existing spring pulses from intervening tributary flows to better understand pallid responses. Combined with existing data, it is possible this will be sufficient to determine if a spring pulse is necessary and the one-time test may not be needed. The preferred alternative does not include a re-occurring flow management action.

Representative Quotes (Correspondence ID): 164
Comments (Comment ID): 641357

Concern Statement: The spring pallid flow release and low summer flow under Alternative 2 would support pallid sturgeon spawning aggregations, synchronicity, and ultimately their success, as well as creating ESH and provide benefits to drifting larval sturgeon by decreasing drift speeds and distances and potentially increase their likelihood of being intercepted into hospitable habitats thereby decreasing mortality rates. Natural variation in flows, higher and lower over the course of the year, is critical to make the aquatic environment which gives the necessary variations in conditions in which all the many species of fish, water insects, macroinvertebrates, and cellular organisms depend for robust populations. These benefits along with others are fully supported.

Response: The low summer flow in Alternative 2 was part of the 2003 Biological Opinion and was analyzed to determine the benefit to the species and impacts to other interests. Alternative 2 was not identified as the preferred alternatives, in part, because of the estimated impacts to other river uses including support for authorized purposes such as water supply and navigation coupled with uncertain benefits for the species. Current information does not indicate that pallid sturgeon require a spring pulse to spawn. Spawning is currently occurring – best evidence shows documented reproduction occurred in 2014 during a “flat” hydrograph. A spring pulse does not appear to be needed to provide food – there is little evidence that pallid sturgeon of any size are food-limited in the Missouri River.

Representative Quotes (Correspondence ID): 179, 237
Comments (Comment ID): 643000, 645209

Concern Statement: Most of the components of Alternative 2 are no longer supported by the latest science and/or have been tried without success. There is also a substantial difference between Alternative 2 and Alternatives 3–6 in the ways that adaptive management is implemented. This difference creates a large discrepancy between Alternative 2 and Alternatives 3–6 and leaves room for alternatives that implement the more proactive management plan. There is a gap concerning adaptive management between Alternative 2 and Alternatives 3–6, leaving room for middle-ground viable alternatives where the proactive adaptive management plan is utilized in accordance with management actions on the scale of Alternative 2. An adaptive management approach should be included under Alternative 2.

Response: Alternatives 1 and 2 represent a different management approach than Alternatives 3–6 because the habitat goals and types described in Alternatives 1 and 2 were largely developed before 2003, prior to the recent effects analysis. The habitat types and goals reflected in Alternatives 3–6 incorporate more recent guidance from USFWS and the results of the effects analysis. It is reasonable to predict the effects of the current course of action (the range of future implementation of the current BiOp is reflected by Alternatives 1 and 2) and compare these to new courses of action. This is a meaningful comparison; the no action alternative does not provide a useful comparison if it assumes the very existence of the plan being proposed.

Representative Quotes (Correspondence ID): 107, 166, 179, 223

Comments (Comment ID): 643882, 644887, 644926, 644949, 645214

Concern Statement: The high cost of Alternative 2 is unacceptable.

Response: Comment noted.

Representative Quotes (Correspondence ID): 23, 176

Comments (Comment ID): 644764

Concern Statement: Low summer flows need to be sufficiently low to provide for shallow water habitat as rearing, refugia, and foraging areas for larval, juvenile, and adult pallid sturgeon.

Response: The low summer flows described as part of Alternative 2 would likely increase the amount of areas meeting the SWH definition for the duration of the low summer flow and would likely be a benefit to nesting terns and plovers. Alternative 2 was not identified as the preferred alternative, in part, because of the estimated impacts to other river uses including support for authorized purposes such as flood control, navigation, water supply, and hydropower. The EIS outlines other alternatives that are anticipated to meet species objectives while being less impactful to other resources and uses.

Representative Quotes (Correspondence ID): 206

Comments (Comment ID): 645146

Concern Statement: Alternative 2 was not intended to be the preferred alternative and was only included due to expectations under NEPA and as a gesture to environmentalists. A minimalist approach was used in development of the alternative primarily in only acquiring a low number of acres per year. This fails the good faith concept. Additionally, changing of unit values made it difficult to impossible to compare the amount of shallow water habitat acres with previous years and slow responses to requests for year-end summaries.

Response: An important point of clarification is that Alternative 2 was developed by USFWS and outlined in a letter to USACE in November of 2015. The same letter was also shared with MRRIC and published with the Draft EIS. Alternative 2 was included to display the impacts and benefits of full implementation of the 2003 Biological Opinion. The same level of impacts assessment and same methods were used across all of the alternatives examined in detail. The No Action Alternative (Alternative 1) and Alternative 2 represent the range of anticipated effects of the 2003 Biological Opinion carried into the future so they could be compared to action alternatives. USACE believes this is rational and is consistent with NEPA. Shallow water habitat goals are presented in terms of acres in the 2003 Biological Opinion. USFWS has defined IRCs in terms of acre/days per year to incorporate flow variability into the definition. This is documented in a planning aid letter

sent to USACE by USFWS on September 14, 2016. This letter was also published with the Draft EIS. Detailed BiOp compliance activities are documented in MRRP annual reports that have been shared with MRRIC and USFWS annually since 2004. Current and past reports are available on the MRRP website: www.moriverrecovery.org.

Representative Quotes (Correspondence ID): 179
Comments (Comment ID): 645207

Concern Statement: The approach used to minimize impacts to human considerations biased the evaluation of possible management actions and weighted the process away from sound biological actions under Alternative 2. Thus, Alternative 2 failed in high costs and impacts to human considerations.

Response: The alternatives are designed to meet the objectives of the plan while taking into account impacts to other resources including “human considerations.” This is consistent with NEPA requirements. An EIS attempts to meet its purpose and need while examining the environmental consequences of alternative ways to meet the purpose and need. The reason for analyzing environmental consequences in a NEPA document is so these impacts can be considered in the decision-making process. USACE developed alternative means of meeting species needs and analyzed the impact of those alternatives on human needs and factored this into identification of a preferred and ultimately a selected alternative as summarized in Section 2.9 of the Final EIS. USACE believes it has selected the alternative that is least impactful across the full range of interests while still meeting species objectives. USACE believes this is a reasonable decision and has taken the full spectrum of considerations into account in the decision-making process and this is well-documented in the Final EIS and supporting materials. Since release of the Draft EIS, USACE has completed formal Section 7 consultation with USFWS and received a non-jeopardy opinion based on implementation of Alternative 3 within the SAMP framework.

Representative Quotes (Correspondence ID): 179
Comments (Comment ID): 645215

Concern Statement: Alternative 2 should be modified to include the SAMP developed for implementation of Alternatives 3–6.

Response: Alternatives 1 and 2 represent a different management approach than Alternatives 3–6 because the habitat goals and types described in Alternatives 1 and 2 were written in 2003, before the recent effects analysis. The habitat types and goals reflected in Alternatives 3–6 incorporate more recent guidance from USFWS and the results of the effects analysis. It is reasonable to predict the effects of the current course of action (the range of future implementation of the current BiOp is reflected by Alternatives 1 and 2) and compare these to new courses of action. This is a meaningful comparison; the no action alternative would not provide a useful comparison if it assumes the very existence of the plan being proposed.

Representative Quotes (Correspondence ID): 149
Comments (Comment ID): 637684, 637683

Concern Statement: Alternative 2 should be modified to include a more ecosystem-wide approach that benefits all wildlife.

Response: Overall ecosystem restoration is outside the scope the Draft EIS. Such a plan would be reflective of the Missouri River Ecosystem Restoration Plan and EIS (MRERP).

Congress has withheld funding for MRERP since 2012 indicating it is not the intent of Congress for MRERP to move forward at this time. In addition, it would not be appropriate to adopt the objectives of MRERP under a different title and continue as if Congress intended the defunded effort to move forward. However, USACE has an obligation under the Endangered Species Act, the MRRP-EIS provides the direction on how USACE will meet those requirements within its need to manage for the authorized purposes.

Representative Quotes (Correspondence ID): 45
Comments (Comment ID): 628645

AL300 *Alternatives: Alternative 3 (Preferred Alternative)*

Concern Statement: The preferred alternative (Alternative 3) should be modified to include more off-channel habitat (non-ESH created habitat) for piping plovers.

Response: USACE considered “Off-Channel” habitat creation and mechanical creation of hydrologically connected non-ESH habitat on Missouri River segments as part of alternatives development. This management action was eliminated from further consideration because it is not currently demonstrated to be as effective or efficient at meeting species objectives relative to other available management actions such as in-river construction of ESH and vegetation management on ESH. Although this action was eliminated from consideration in the Draft EIS, USFWS has expressed a willingness to pursue funding for a pilot project. This funding would not be through the USACE MRRP; however, the results of any pilot project could be evaluated under the SAMP. As stated in the SAMP, long-term changes off-river affecting Missouri River populations may require adjustments to target criteria or objectives. The AM process would incorporate the results of future metapopulation modeling as it becomes available in order to improve management decisions.

Representative Quotes (Correspondence ID): 172
Comments (Comment ID): 641804

Concern Statement: **Concern Statement:** The preferred alternative should be modified to include additional emphasis on the pallid sturgeon science, sediment management as a component of the management plan, and address flow constraints from Fort Randall.

Response: The SAMP outlines a comprehensive and structured approach for conducting pallid sturgeon science and incorporating the results into future management. As described in Section 2.10 USACE will continue to analyze how the flow release under the preferred alternative may impact private landowners and if these impacts are covered by any existing easements. Where an easement does not already exist, USACE will continue to effectively strategize how to minimize the impacts over the next nine years. Sediment transport issues are the subject of the Lewis and Clark sediment management study funded by the MRRP (available at www.moriverrecovery.org). Phase II of this study is ongoing. In the future, it is likely that MRRP will continue to fund sediment management studies where sediment issues intersect with ESA issues.

Representative Quotes (Correspondence ID): 206
Comments (Comment ID): 645153

Concern Statement: There is concern that the one-time flow test could become a permanent flow regime. This action should be removed from the preferred alternative.

Response: The preferred alternative includes nine years of study of existing spring pulses from intervening tributary flows to better understand pallid responses. Combined with existing data, it is possible this will be sufficient to determine if a spring pulse is necessary and the one-time test may not be needed.

Representative Quotes (Correspondence ID): 27, 30, 64, 107, 159, 173, 176, 197, 204, 206, 230

Comments (Comment ID): 626704, 626827, 633522, 641013, 641389, 642772, 643515, 644443, 644453, 644746, 645128, 645243, 645878

Concern Statement: Alternative 3 would require indefinite work and maintenance due to its dependence on manual, artificially created habitat.

Response: Each of the alternatives would entail significant maintenance of constructed habitat. Maintenance costs would be highest under Alternative 2 which calls for increased acreage of constructed ESH and SWH. Maintenance costs do not differ significantly between the other alternatives as described in the cost estimates appendix of the EIS (Appendix F).

Representative Quotes (Correspondence ID): 41

Comments (Comment ID): 627007

Concern Statement: Alternative 3 or 6 provides the best opportunity for further study of the pallid sturgeon with the least adverse effect on human considerations.

Response: Comment noted. Alternative 3 was identified as the preferred alternative.

Representative Quotes (Correspondence ID): 91

Comments (Comment ID): 627568

Concern Statement: The one-time flow test should be removed from the preferred alternative due to the lack of science to support any value.

Response: The preferred alternative includes nine years of study of existing spring pulses from intervening tributary flows to better understand pallid responses. Combined with existing data, it is possible this will be sufficient to determine if a spring pulse is necessary and the one-time test may not be needed.

Representative Quotes (Correspondence ID): 33, 65, 107

Comments (Comment ID): 628017, 631573, 643883

Concern Statement: The preferred alternative is inadequate because of the absence of acquiring additional floodplain acres and constructing shallow water habitat.

Response: The preferred alternative includes purchasing of floodplain acres from willing sellers where needed using the BSNP Mitigation authority. The acres would be used to support IRC habitat and surrounding terrestrial areas would be developed as additional habitat. The preferred alternative involves constructing IRC habitat rather than SWH. Previous channel restoration efforts on the lower Missouri River focused on adding SWH (areas 0-5 feet deep, 0-2 feet per second current velocity). IRCs by comparison are designed specifically to provide three ecological attributes (interception hydraulics, food production habitat, and foraging habitat) to support sturgeon growth and survival. These three attributes can individually be designed to provide optimal habitat and survival benefits tailored to particular river reaches. IRCs occupy locations similar to SWH projects, but they are designed specifically to provide these three needed attributes.

Comments (Comment ID): 628479

Concern Statement: The MRRMP-EIS should increase IRC construction under Alternative 3.

Response: Alternative 3 contains the amount of IRC construction needed to test the concept to see if it is effective. Alternative 3 also includes additional flexibility to add more IRCs should they be determined to be effective. The acreages of IRC in Alternatives 3–6 are in alignment with recommended levels of IRC presented to USACE from USFWS via planning aid letter in September of 2016.

Representative Quotes (Correspondence ID): 42, 207
Comments (Comment ID): 628511, 643519

Concern Statement: Alternative 3 is the least sustainable alternative due to the use of all mechanical construction and does not include an adequate amount of IRC construction.

Response: Alternative 3 contains the amount of IRC construction needed to test the concept to see if it is effective. Alternative 3 also includes additional flexibility to add more IRCs should they be determined to be effective. The acreages of IRC in Alternatives 3–6 are in alignment with recommended levels of IRC presented to USACE from USFWS via planning aid letter in September of 2016. Each of the alternatives would entail significant maintenance of constructed habitat. Maintenance costs would be highest under Alternative 2 which calls for increased acreage of constructed ESH and SWH. Maintenance costs do not differ significantly between the other alternatives as described in the cost estimates appendix of the EIS (Appendix F).

Representative Quotes (Correspondence ID): 50
Comments (Comment ID): 628615

Concern Statement: The MRRMP-EIS should describe the process for creating mechanical habitat if funding is not available in the future.

Response: If funding is not available to accomplish habitat construction or any other major component of the plan then USACE would likely re-initiate formal consultation with USFWS and a different path-forward would potentially be determined.

Representative Quotes (Correspondence ID): 55
Comments (Comment ID): 631092

Concern Statement: Alternative 3 is unlikely to reach the goal of 11,886 acres of ESH on the Missouri River.

Response: Alternative 3 is not designed to meet the goal of 11,886 acres of ESH on the Missouri River, it is designed to meet the 95 percent probability of persistence objectives developed by USFWS. The 11,886 acres of ESH is a goal from the 2003 BiOp that is based on the amount of habitat present in the system after flooding in 1997 had created large amounts of ESH in the upper river. Best available science indicates that this amount of habitat is not needed to meet the 95 percent probability of persistence goals outlined by USFWS.

Representative Quotes (Correspondence ID): 63
Comments (Comment ID): 632134

Concern Statement: Alternative 3 is inadequate in repairing the natural ecosystem and is not financially sustainable. Alternative 3 will only facilitate the reestablishment of most of the components needed to recover the pallid sturgeon, piping plover, and least tern and avoid jeopardy. Alternative 3 should include the management action included under Alternatives 4, 5, and 6 that include actions that mimic historic natural flows and habitat.

Response: Alternative 3 is designed to restore components of the ecosystem thought to be important to the three listed species based on best available science. Alternative 3 also includes a comprehensive SAMP designed to continually update the scientific knowledge base and incorporate this knowledge into management actions on the ground. Each of the alternatives would entail significant maintenance of constructed habitat. Maintenance costs would be highest under Alternative 2 which calls for increased acreage of constructed ESH and SWH. Maintenance costs do not differ significantly between the other alternatives as described in the cost estimates appendix of the EIS (Appendix F). Alternative 3 was chosen as the preferred alternative because it is anticipated to meet species objectives while avoiding impacts to other resources that occur under Alternatives 4, 5, and 6.

Representative Quotes (Correspondence ID): 103
Comments (Comment ID): 636883

Concern Statement: Alternative 3 does not do enough to conserve and protect the natural resources of the Missouri River due to the lack of flows. Establishing a more natural flow regime in combination with habitat construction through an adaptive management plan is a more prudent approach.

Response: Rather than a comparison to historical pre-dam and pre-bank stabilization conditions, USACE believes the science and adaptive management approach that consists of research, monitoring of natural flow events, and potential test flows is more likely to be successful given the extensive modifications to the Missouri River to support authorized purposes. The flows for ESH creation are scientifically supported. We have a population model that predicts the response of terns and plovers to different ESH creating flow events and those results are provided in the EIS. The analysis shows, however, that objectives for terns and plovers can be met without the use of intentional ESH flows and incurring the associated impacts to other resources.

Representative Quotes (Correspondence ID): 149, 179
Comments (Comment ID): 637677, 645206

Concern Statement: Alternative 3 should include a substantially greater commitment to land acquisition, floodplain connectivity, and habitat restoration.

Response: Alternative 3 contains the amount of IRC construction needed to test the concept to see if it is effective. Alternative 3 also includes additional flexibility to add more IRCs should they be determined to be effective. The acreages of IRC in Alternatives 3–6 are in alignment with recommended levels of IRC presented to USACE from USFWS via planning aid letter in September of 2016. As described in the EIS, the BSNP land acquisition authority would be used to purchase lands from willing sellers as needed for IRCs and surrounding terrestrial areas would also be developed as habitat. Use of the BSNP Mitigation Authority to potentially improve conditions for endangered species is also a component of the ESA 7(a)(1) Plan. USACE coordinated with USFWS during development of Alternative 2 to identify criteria for clarification of the floodplain connectivity language from the 2003 BiOp. The 2003 BiOp did not contain numeric

criteria for floodplain connectivity. USFWS provided these criteria in a Planning Aid Letter submitted to USACE on November 5, 2015. The criteria stated that the management action should maximize floodplain habitat by ensuring that 77,410 acres of connected floodplain are inundated at a 20 percent annual chance exceedance. This acreage amount was an interpretation, made in 2015, of the language from the 2003 BiOp developed to inform alternatives development. USACE conducted HEC-GeoRAS mapping to determine the acres of existing floodplain connectivity in the lower Missouri River. This was the first time this type of an analysis had been done. The mapping results indicated that 147,650 acres of floodplain connectivity are currently present, not including the area of the main channel. Under each Alternative, it is assumed that normal operations combined with tributary inflow would result in floodplain connectivity of at least 77,410 acres as indicated by the mapping results described previously, thus no additional action would be required. This analysis should not be interpreted to indicate that floodplain connectivity has increased from 77,410 acres to 147,650 acres from 2003 to present. Only that current normal operations combined with tributary inflow are meeting numeric criteria for floodplain connectivity developed by USFWS in 2015.

Representative Quotes (Correspondence ID): 178
Comments (Comment ID): 641437

Concern Statement: Due to the uncertainty of the alternatives and the actions needed for the pallid sturgeon, piping plover, and least tern there is uncertainty in the success of these actions. Additionally, the one-time flow test is opposed.

Response: The preferred alternative outlines an initial set of actions that can be implemented as more is learned about species needs. The SAMP is designed to reduce uncertainty and feed new knowledge back into implementation decisions. The preferred alternative includes nine years of study of existing spring pulses from intervening tributary flows to better understand pallid responses. Combined with existing data, it is possible this will be sufficient to determine if a spring pulse is necessary and the one-time test may not be needed.

Representative Quotes (Correspondence ID): 189
Comments (Comment ID): 641574

Concern Statement: The preferred alternative should not threaten navigation.

Response: The preferred alternative does not include a split navigation season or otherwise threaten commercial navigation.

Representative Quotes (Correspondence ID): 192, 194, 212
Comments (Comment ID): 641641, 641710, 641725

Concern Statement: The preferred alternative should enhance the research surrounding Big Questions 1: Spawning Cues and include Level 2 experimental flow decreases from Gavins Point Dam in addition to the proposed release. These decreases would be timed to coincide with high flow events at appropriate water temperatures (spawning) occurring on the tributaries near Gavins Point Dam to attempt to enhance localized temperature and turbidity - known factors impacting pallid spawning behaviors. Additionally, the preferred alternative should evaluate and implement low stable flows during known periods of peak aquatic-insect laying. The Nature Conservancy also believes evaluation of the impacts on these same insects by harassment flows to discourage bird nesting on low sandbar elevations should be considered.

Response: At this point, there does not appear to be evidence that temperature and/or turbidity are needed to cue pallid sturgeon spawning below Gavins Point Dam. Spawning is currently occurring – best evidence shows documented reproduction occurred in 2014 during a “flat” hydrograph. The preferred alternative includes nine years of study of existing spring pulses from intervening tributary flows to better understand pallid responses. Combined with existing data, it is possible this will be sufficient to determine if a spring pulse is necessary and the one-time test may not be needed. If temperature and/or turbidity are determined to be factors limiting spawning then level 2 experimental releases can be added at a future date through the science and adaptive management process. The Final EIS contains an analysis of flow management to reduce take of birds and the potential impacts to aquatic insects. This analysis is provided in Section 3.5 of the Final EIS.

Representative Quotes (Correspondence ID): 148, 229

Comments (Comment ID): 642691, 644899

Concern Statement: The number of spawning habitat sites included under Alternative 3 is insufficient and should include more.

Response: The intent of spawning site creation is to stimulate aggregation of males and females in one location for spawning; too many sites would potentially lead to further disaggregation. In the case of spawning habitat, USACE believes it is more prudent to develop one site as a pilot project prior to expanding that site if it proves to be effective.

Representative Quotes (Correspondence ID): 207

Comments (Comment ID): 643518

Concern Statement: There is concern about the knowledge concerning requirements for pallid sturgeon spawning and rearing habitat and these proposed actions in the MRRMP-EIS. Coordination between USACE and stakeholders regarding design, location, and implementation is important.

Response: A process to coordinate design, location, and implementation is being developed with MRRIC. Initial planning for the Langdon Bend project was conducted in February of 2014. All environmental compliance and National Environmental Policy Act requirements were satisfied and documented in a Project Implementation Report with Integrated Tiered Environmental Assessment and Finding of No Significant Impact. A 30-day public comment period began June 20, 2016 and ended July 20, 2016. No Recommendations from MRRIC nor comments from the members of MRRIC were received. As with all habitat sites, this site will be monitored and, if warranted, adjusted through the adaptive management process. Consistent with Langdon Bend and in addition to the IRCs included within the study design, MRRP will be modifying existing chutes and SWH to better incorporate the concepts of IRC. Any additional necessary environmental documentation will be completed as required by law.

Representative Quotes (Correspondence ID): 107

Comments (Comment ID): 643906

Concern Statement: The suite of actions in the preferred alternative alone may not meet the purpose and objectives of the Draft MRRMP-EIS. The near-complete reliance upon mechanical construction in the Missouri River system overlooks the value of ecological functions to support the program purposes. Restoring natural flows should be a cornerstone of management approaches to river ecosystems, yet the current Draft

MRRMP-EIS preferred alternative only includes them as a potential for testing the applicability of flows.

Response: Rather than a comparison to historical pre-dam and pre-bank stabilization conditions, USACE believes the science and adaptive management approach that consists of research, monitoring of natural flow events, and potential test flows is more likely to be successful given the extensive modifications to the Missouri River to support authorized purposes. The flows for ESH creation are scientifically supported. We have a population model that predicts the response of terns and plovers to different ESH creating flow events and those results are provided in the EIS. The analysis shows, however, that objectives for terns and plovers can be met without the use of intentional ESH flows and incurring the associated impacts to other resources.

Representative Quotes (Correspondence ID): 183
Comments (Comment ID): 643928

Concern Statement: The preferred alternative does not address the identification and removal of impediments to implement more natural flows in the Missouri River. The Final MRRMP-EIS should consider the use of land acquisition, flowage easements, coordination with landowners, and necessary site preparations, within the 15-year project implementation period to achieve the purpose and objectives of the Draft MRRMP-EIS.

Response: Rather than a comparison to historical pre-dam and pre-bank stabilization conditions, USACE believes the science and adaptive management approach that consists of research, monitoring of natural flow events, and potential test flows is more likely to be successful given the extensive modifications to the Missouri River to support authorized purposes. The flows for ESH creation are scientifically supported. We have a population model that predicts the response of terns and plovers to different ESH creating flow events and those results are provided in the EIS. The analysis shows, however, that objectives for terns and plovers can be met without the use of intentional ESH flows and incurring the associated impacts to other resources.

Representative Quotes (Correspondence ID): 183
Comments (Comment ID): 643935

Concern Statement: The preferred alternative (Alternative 3) is too limited in scope and it does not provide sufficient consideration for ecological function and other river resources. The preferred alternative should include management actions that achieve closer to natural flow regimes, such as those in Alternative 2.

Response: Rather than a comparison to historical pre-dam and pre-bank stabilization conditions, USACE believes the science and adaptive management approach that consists of research, monitoring of natural flow events, and potential test flows is more likely to be successful given the extensive modifications to the Missouri River to support authorized purposes. The flows for ESH creation are scientifically supported. We have a population model that predicts the response of terns and plovers to different ESH creating flow events and those results are provided in the EIS. The analysis shows, however, that objectives for terns and plovers can be met without the use of intentional ESH flows and incurring the associated impacts to other resources.

Representative Quotes (Correspondence ID): 183
Comments (Comment ID): 643950

Concern Statement: The preferred alternative should include other traditional shallow water habitat construction projects (bank notches, dike notches, revetment notches, placement of new structures, side channels, chutes, and channel widening/top-width widening) and should continue to be considered throughout the lower river because of their demonstrated effectiveness in providing multiple species benefits, along with flood control and water quality improvements.

Response: Techniques such as bank notching, dike notching, revetment notches, placement of new structures, and channel widening are potential methods to construct IRC habitat. There is still uncertainty about the effectiveness of the IRC concept including optimal distribution, size, and quantity. The preferred alternative analyzed the impacts of creating 276 acres of IRC from Sioux City to the Platte River, 585 acres from the Platte River to Rulo, 670 acres from Rulo to the Kansas River, 1,389 from the Kansas River to the Osage River, and 460 acres from the Osage River to the mouth.

Representative Quotes (Correspondence ID): 224
Comments (Comment ID): 644397

Concern Statement: Any mechanical habitat construction should be undertaken in a manner that avoids, to the greatest extent possible, deposition of sediment back into the Missouri River.

Response: Potential downstream sediment impacts will be examined for each channel modification project and if sediment impacts are identified then ways to reduce impacts will be examined. Each project will also include State Section 401 water quality certification.

Representative Quotes (Correspondence ID): 224
Comments (Comment ID): 644409

Concern Statement: Level 2 studies would have no effect on pallid sturgeon living in the river and insufficient statistical power to overcome what is, essentially, a policy decision preference for an intervention under the preferred alternative that may not work.

Response: Level 1 studies are research studies without changes to the system (laboratory or field studies under ambient river conditions). By definition, level 2 studies take place in the river. Level 2 actions are implemented at a sufficient level to expect a measurable biological, behavioral, or physiological response in pallid sturgeon, surrogate species, or related habitat response. Prior to implementing any level 2 study in the river, or level 1 studies monitoring ambient conditions, a statistical power analysis will be performed to ensure the study designed in a way that produces meaningful information. For example, as part of implementing IRC habitat under the preferred alternative a statistical power analysis was conducted that was used in determining the extent of monitoring and sampling intensity at IRC and control sites required to observe an effect.

Representative Quotes (Correspondence ID): 166
Comments (Comment ID): 644851

Concern Statement: The preferred alternative is insufficient at avoiding jeopardy for the pallid sturgeon, piping plover, and least tern.

Response: USFWS has issued a non-jeopardy opinion on implementation of the preferred alternative under the SAMP.

Representative Quotes (Correspondence ID): 166
Comments (Comment ID): 644860

Concern Statement: The Draft MRRMP-EIS seems to lack any detail on the amount of acquired land would occur or the types of habitat development.

Response: As described in Section 2.8.4 of the EIS under the preferred alternative approximately 1,772 acres of additional land would be projected to be purchased in association with IRC habitat construction. As described in Section 2.5.4 of the EIS the land acquisition authority for mitigation of the construction of the BSNP is not being reassessed through this Management Plan and the total mitigation authority acres remain at 166,750 acres. USACE has acquired approximately 66,616 acres of the authorized 166,750 acres, nearly 40 percent. Land acquisition and habitat development under the BSNP mitigation authority is not limited to pallid sturgeon habitat and can include restoration of native vegetation, wetlands, bottomland forest, backwaters and other Missouri River habitats lost due to the BSNP. Appropriate vegetation and habitat types are determined on a site-specific basis. It is assumed that real-estate purchases for the 15-year implementation timeframe would continue to prioritize land that contributes to jeopardy avoidance, while still constituting appropriate acquisition and development under the WRDA authorities. The current budgetary priority is on ESA compliance rather than habitat acquisition and creation for non-listed species. If budgetary priorities change the necessary authorities and NEPA framework (the 2003 Supplemental EIS for BSNP Mitigation) are already in place to fully implement BSNP mitigation.

Representative Quotes (Correspondence ID): 229
Comments (Comment ID): 644901

Concern Statement: The MRRMP-EIS should provide an explanation of how it will meet the goal of reproducing the effect of floodplain connectivity and inundation as recommended by USFWS.

Response: Best available science at this time does not indicate that pallid sturgeon of any age are food limited or that floodplain connectivity would increase pallid spawning habitat. USACE coordinated with USFWS during development of Alternative 2 to identify criteria for clarification of the floodplain connectivity language from the 2003 BiOp. The 2003 BiOp did not contain numeric criteria for floodplain connectivity. USFWS provided these criteria in a Planning Aid Letter submitted to USACE on November 5, 2015. The criteria stated that the management action should maximize floodplain habitat by ensuring that 77,410 acres of connected floodplain are inundated at a 20 percent annual chance exceedance. This acreage amount was an interpretation, made in 2015, of the language from the 2003 BiOp developed to inform alternatives development. USACE conducted HEC-GeoRAS mapping to determine the acres of existing floodplain connectivity in the lower Missouri River. This was the first time this type of an analysis had been done. The mapping results indicated that 147,650 acres of floodplain connectivity are currently present, not including the area of the main channel. Under each Alternative, it is assumed that normal operations combined with tributary inflow would result in floodplain connectivity of at least 77,410 acres as indicated by the mapping results described previously, thus no additional action would be required. This analysis should not be interpreted to indicate that floodplain connectivity has increased from 77,410 acres to 147,650 acres from 2003 to present. Only that current normal operations combined with

tributary inflow are meeting numeric criteria for floodplain connectivity developed by USFWS in 2015.

Representative Quotes (Correspondence ID): 166, 131
Comments (Comment ID): 644928, 645761

Concern Statement: Expanding the budget for level 1 and level 2 research on the effectiveness of physical habitat creation and modification within the current river channel needs to be a priority. However, if research indicates these habitats are contributing to reproduction and recruitment of pallid sturgeon, the goal of 20 acres of shallow water habitat or IRC per river mile should be increased to 30 acres per river mile, the upper end of the range specified in the 2003 Amended Biological Opinion. Additionally, the research effort should be increased such that in 9-10 years, there is sufficient information to determine if flow modifications to annual operations of the system are needed to support pallid sturgeon recovery.

Response: Level 1 and Level 2 activities have been outlined in-detail in the SAMP and funding will be prioritized for these activities. The appropriate size, distribution, and number of sites will be determined through the AM process rather than defaulting to SWH acreage goals provided in the 2003 Biological Opinion. The preferred alternative lays out an incremental approach to increase the amount of IRC habitat should it be deemed effective. Level 1 studies during the first 9 years will be designed to produce statistically valid results used to determine if a bi-modal pulse is needed for successful spawning.

Representative Quotes (Correspondence ID): 206
Comments (Comment ID): 645130

Concern Statement: The MRRMP-EIS should implement the preferred alternative in a manner that would provide both beneficial habitat and improve overall channel flow conveyance and habitat construction activities within the navigation channel should be implemented only after these deficient structures are brought up to their original design dimensions.

Response: Site-specific IRC projects will be located and designed in a manner that avoids or minimizes impacts to the authorized purposes including navigation. Each site will include site-specific planning and NEPA compliance including coordination with the public, States, Tribes, and stakeholders.

Representative Quotes (Correspondence ID): 197
Comments (Comment ID): 645242

Concern Statement: The MRRMP-EIS should provide further explanation of how the ESH acres would be distributed between the reaches under the preferred alternative.

Response: Additional detail regarding the modeled distribution of ESH habitat construction has been added to the Final EIS.

Representative Quotes (Correspondence ID): 239
Comments (Comment ID): 645380

Concern Statement: Additional detail should be included in the MRRMP-EIS on the size, location, and timing of construction for the three spawning habitat construction sites.

Response: At this point the ideal location and size for spawning habitat construction is unknown. Several Level 1 and Level 2 studies are outlined in the SAMP that will be used to determine locations, substrate, and size.

Representative Quotes (Correspondence ID): 242
Comments (Comment ID): 645513

Concern Statement: The sequential approach in the preferred alternative (Alternative 3) further delays meaningful conservation of pallid sturgeon in the upper Missouri River basin through unnecessary reliance on Level 1 and Level 2 studies.

Response: The Effects Analysis and SAMP were developed by a team of internationally recognized experts in sturgeon biology, tern and plover biology, population modeling, adaptive management, and other related fields. The Effects Analysis and SAMP have been thoroughly reviewed by an independent science advisory panel consisting of internationally recognized experts in the field. USACE and USFWS believe the Effects Analysis represents the best available science related to the three species. The incremental approach described in the SAMP is based on the results of the Effects Analysis and provides a process where hypotheses can be tested and the agencies can adjust as more is learned. Science and implementation activities are scheduled in detail in the plan to avoid delays in knowledge acquisition and implementation.

Comments (Comment ID): 643285

AL400, AL500, AL600 Alternatives: Alternative 4, Alternative 5, Alternative 6

Concern Statement: Alternatives 4, 5, and 6 create unacceptable amounts of flooding risk in the spring or fall, increasing downstream flood control constraints, impacts to interior drainage, and doubling releases from Gavins Point.

Response: As discussed in detail in Section 3.12, beginning on page 3-261 in the Draft EIS, Flood Risk Management and Interior Drainage were discussed and evaluated for each of the alternatives. Alternatives 4, 5, and 6 were not identified as the preferred alternative, in part, because of the estimated impacts to other river uses including support for authorized purposes such as flood risk management coupled with uncertain benefits for the species. The preferred alternative includes nine years of study of existing spring pulses from intervening tributary flows to better understand pallid responses. Combined with existing data, it is possible this will be sufficient to determine if a spring pulse is necessary and the one-time test may not be needed.

Representative Quotes (Correspondence ID): 33, 64, 65, 98, 144, 154
Comments (Comment ID): 628008, 631571, 633520, 633684, 633916, 640728, 646364, 626700

Concern Statement: There is opposition to Alternatives 4 and 5 as they still allow for spring or fall flows for the pallid sturgeon without the science to suggest its effectiveness.

Response: The spring flow included in Alternative 4 and the fall flow included in Alternative 5 are for Emergent Sandbar Habitat Creation, not for pallid sturgeon benefit. Alternatives 4 and 5 were not identified as the preferred alternative, in part, because of the estimated impacts to other river uses including support for authorized purposes such as flood risk management coupled with uncertain benefits for the species. The preferred alternative includes nine years of study of existing spring pulses from intervening tributary flows to better understand pallid responses. Combined with existing data, it is possible this will be sufficient to determine if a spring pulse is necessary and the one-time test may not be needed.

Representative Quotes (Correspondence ID): 187
Comments (Comment ID): 641563

Concern Statement: The EIS should verify that flow duration parameters in Section 2.7.3 pg. 2-40 have been verified in the river.

Response: The model used to estimate flow durations needed to create 500 acres of ESH uses available observed river data; however, the model will be improved in the future as additional monitoring information is collected and fed back into the model. The model is a planning tool rather than a more exact representation of observed conditions.

Representative Quotes (Correspondence ID): 107
Comments (Comment ID): 643867

Concern Statement: Alternative 4 appears to benefit downstream interests to the detriment of upstream users, such as power generation.

Response: USACE agrees that Alternative 4 can have adverse impacts to thermal power plants in Garrison Reach, which seem to occur following a spring release when there is less water available for subsequent releases from Lake Sakakawea when compared to No Action. Power plants in the lower river would also experience some adverse impacts from flow releases under Alternative 4 as well. However, the NED model indicates that power plants in the lower river would experience some increases in power generation under Alternative 4 because river temperatures would be slightly lower in the lower river than under No Action. Not all resources benefit from the flow releases in the lower river from the Alternative 4. Water supply and irrigation water intakes can experience adverse effects in the year or years following a flow release from reduced access to water. Flood risks can also increase during the release years as well in the lower river. Alternative 4 was not identified as the preferred alternative, in part, because of the estimated impacts to other river uses including support for authorized purposes such as power generation coupled with uncertain benefits for the species. The preferred alternative includes nine years of study of existing spring pulses from intervening tributary flows to better understand pallid responses. Combined with existing data, it is possible this will be sufficient to determine if a spring pulse is necessary and the one-time test may not be needed.

Representative Quotes (Correspondence ID): 167
Comments (Comment ID): 643873

Concern Statement: Alternatives 3–6 fail to meet the minimum floodplain connectivity and inundation recommended by USFWS or how it would achieve the goal of 11,886 acres of ESH.

Response: USACE coordinated with USFWS during development of Alternative 2 to identify criteria for clarification of the floodplain connectivity language from the 2003 BiOp. The 2003 BiOp did not contain numeric criteria for floodplain connectivity. USFWS provided these criteria in a Planning Aid Letter submitted to USACE on November 5, 2015. The criteria stated that the management action should maximize floodplain habitat by ensuring that 77,410 acres of connected floodplain are inundated at a 20 percent annual chance exceedance. This acreage amount was an interpretation, made in 2015, of the language from the 2003 BiOp developed to inform alternatives development. USACE conducted HEC-GeoRAS mapping to determine the acres of existing floodplain connectivity in the lower Missouri River. This was the first time this type of an analysis had been done. The mapping results indicated that 147,650 acres of floodplain

connectivity are currently present, not including the area of the main channel. Under each Alternative, it is assumed that normal operations combined with tributary inflow would result in floodplain connectivity of at least 77,410 acres as indicated by the mapping results described previously, thus no additional action would be required. This analysis should not be interpreted to indicate that floodplain connectivity has increased from 77,410 acres to 147,650 acres from 2003 to present. Only that current normal operations combined with tributary inflow are meeting numeric criteria for floodplain connectivity developed by USFWS in 2015. Alternatives 3–6 are not designed to meet the goal of 11,886 acres of ESH on the Missouri River, they are designed to meet the 95 percent probability of persistence objectives developed by USFWS. The 11,886 acres of ESH is a goal from the 2003 BiOp that is based on the amount of habitat present in the system after flooding in 1997 had created large amounts of ESH in the upper river. Best available science indicates that this amount of habitat is not needed to meet the 95 percent probability of persistence goals outlined by USFWS.

Representative Quotes (Correspondence ID): 63, 131, 166
Comments (Comment ID): 644928, 645761, 645762

Concern Statement: Alternatives 2 and 5 would have a degree of unacceptable uncertainty in impacts associated with USACE holding back flows to maintain volume in upstream reservoirs.

Response: The Master Manual indicates that the water control plan's purpose is to meet water supply requirements to the extent reasonably possible. The minimum Garrison releases in the Master Manual that are considered adequate to meet water intake or water quality requirements are used in each alternative. Although USACE can help meet short-term intake requirements (e.g., increasing releases for a short period to ensure an intake can access water), it is the intake owners' responsibility to ensure that their intake is operational under the range of flows specified in the Master Manual. Alternative 5 was not identified as the preferred alternative, in part, because of the estimated impacts to other river uses including support for authorized purposes such as water supply coupled with uncertain benefits for the species. The preferred alternative includes nine years of study of existing spring pulses from intervening tributary flows to better understand pallid responses. Combined with existing data, it is possible this will be sufficient to determine if a spring pulse is necessary and the one-time test may not be needed.

Representative Quotes (Correspondence ID): 167
Comments (Comment ID): 643872

Concern Statement: Reservoir releases will impact thermal power and the value of the water released to create ESH should be determined in order to assess the total cost to stakeholders.

Response: Most human considerations topics have NED and RED evaluations; some of the evaluations include cost-based evaluations, while others are focused on the change in benefits under the alternatives. The RED evaluation includes various geographies depending on the resource under evaluation. In addition, some of the adverse impacts from the flow releases occur in release years, while other impacts occur in the year following a release and sometimes multiple years following a release. It would be inaccurate to aggregate all of these estimates to attempt to estimate all impacts associated with a flow release for ESH creation. The consequence table in the Chapter 2 (Tables 2-30 and 2-31) summarizes all of the possible consequences on average

associated with the alternatives; Chapter 3 and the technical reports further explain the annual economic impacts associated with each of the human considerations.

Representative Quotes (Correspondence ID): 107
Comments (Comment ID): 643884, 643885

Concern Statement: Alternatives 4 and 5 will not achieve desired flow release ESH habitat creation objectives due to the limited amount of time the flow releases would be fully implemented.

Response: With the exception of Alternative 1, all of the alternatives were projected to meet the 95 percent probability of persistence targets determined by USFWS.

Representative Quotes (Correspondence ID): 223
Comments (Comment ID): 644951

Concern Statement: USACE should manage flows after the fall flow release to restore the elevation of the big-three storage reservoirs to the base of the annual flood control pool by March 1st of each year.

Response: The preferred alternative does not include a fall flow release, however if a fall release were to be implemented in the future, USACE would attempt to manage flows to restore the elevation to the base of the annual flood control pool if possible.

Representative Quotes (Correspondence ID): 206
Comments (Comment ID): 645144

Concern Statement: There is opposition to Alternatives 1, 2, and 6 as it still allows for bi-modal spring rise for the pallid sturgeon without the science to suggest its effectiveness.

Response: Alternative 6 was not identified as the preferred alternative, in part, because of the estimated impacts to other river uses including support for authorized purposes coupled with uncertain benefits for the species. The preferred alternative includes nine years of study of existing spring pulses from intervening tributary flows to better understand pallid responses. Combined with existing data, it is possible this will be sufficient to determine if a spring pulse is necessary and the one-time test may not be needed.

Comments (Comment ID): 633683, 641563, 643886, 645376, 645450, 646363

Concern Statement: Please clarify what is meant by the term “the preclude” on page 2-73.

Response: The term "preclude" was removed when referring to spawning cues and ESH releases. The term is in reference to a set of circumstances that would stop the flow from occurring. The spawning cues and ESH releases have System storage checks that determine if the releases will occur. The drought preclude of 31.0 MAF used on the March 15 storage check to determine if there will be navigation season does not change in any of the alternatives.

AL4000 *Alternatives: New Alternatives or Elements*

Concern Statement: USACE is encouraged to meet mitigation objectives from willing sellers by purchasing less costly lands worthy of habitat substitution for all species, not just protected species.

Response: The actions in the EIS are designed to fulfill endangered species act responsibilities although a variety of fish and wildlife species would benefit as outlined in Chapter 3 of the EIS. The acres would be used to support IRC habitat and surrounding terrestrial areas would be developed as additional habitat. The Bank Stabilization and Navigation Mitigation Project is linked to every alternative in the Management Plan. It is the authority that would be used to purchase land from willing sellers and develop habitat under each alternative as explained in the EIS.

Representative Quotes (Correspondence ID): 222
Comments (Comment ID): 644792

Concern Statement: Emphasis should be placed on acquiring more acres of land for development of natural habitat for the adult pallid sturgeon and then accelerated if monitoring demonstrates success. Perhaps a hybrid of Alternatives 2 and 3.

Response: Alternative 3 contains the amount of IRC construction needed to test the concept to see if it is effective. Alternative 3 also includes additional flexibility to add more IRCs should they be determined to be effective. The acreages of IRC in Alternatives 3–6 are in alignment with recommended levels of IRC presented to USACE from USFWS via planning aid letter in September of 2016. As described in the EIS, the BSNP land acquisition authority would be used to purchase lands from willing sellers as needed for IRCs and surrounding terrestrial areas would also be developed as habitat. Use of the BSNP Mitigation Authority to potentially improve conditions for endangered species is also a component of the ESA 7(a)(1) Plan.

Comments (Comment ID): 626567, 628485, 628512, 640077

Concern Statement: Some levees should be set back and controlled release structures placed using LiDAR elevation and GIS imaging.

Response: Levee setbacks have occurred on MRRP acquired lands in the past and could be considered in the future should floodplain connectivity or other levee setback benefit become necessary. At this time, however, pallid sturgeon do not appear to be food limited and spawning success does not appear to be related to floodplain connectivity.

Representative Quotes (Correspondence ID): 68
Comments (Comment ID): 633534

Concern Statement: USACE and USFWS should seek an alternative which allows USACE to provide flood control and protect the species at the same time; a better balance needs to be reached.

Response: USACE believes that Alternative 3 achieves the balance between flood risk reduction and species protection. The preferred alternative includes nine years of study of existing spring pulses from intervening tributary flows to better understand pallid responses. Combined with existing data, it is possible this will be sufficient to determine if a spring pulse is necessary and the one-time test may not be needed.

Representative Quotes (Correspondence ID): 140
Comments (Comment ID): 633862

Concern Statement: Current science validates that a broader and more dynamic management plan is needed for species recovery than just a mechanical construction only option.

Response: The Effects Analysis and SAMP were developed by a team of internationally recognized experts in sturgeon biology, tern and plover biology, population modeling, adaptive management, and other related fields. The Effects Analysis and SAMP have been thoroughly reviewed by an independent science advisory panel consisting of internationally recognized experts in the field. USACE and USFWS believe the Effects Analysis represents the best available science related to the three species. The SAMP is based on the results of the Effects Analysis and provides a process where hypotheses can be tested and the agencies can adjust as more is learned. Science and implementation activities are scheduled in detail in the plan to avoid delays in knowledge acquisition and implementation. The SAMP outlines a comprehensive and structured approach for conducting pallid sturgeon science and incorporating the results into future management. USACE believes implementation of the initial actions outlined in Alternative 3 combined with the SAMP offers a higher likelihood of success for the three species rather than implementation of full scale management actions that could have significant impacts with very uncertain benefits.

Representative Quotes (Correspondence ID): 103
Comments (Comment ID): 636886

Concern Statement: The inevitable and ongoing channel degradation below Missouri River dams means there will be less production of natural sandbars into the future; thus, the navigation channel should be modified to have a more natural cross-section to benefit the pallid sturgeon.

Response: Channel degradation is the subject of several ongoing studies. Natural sandbars are not currently identified as a limiting factor for pallid sturgeon, therefore sandbar creation was not included as a management action for pallid sturgeon.

Representative Quotes (Correspondence ID): 157
Comments (Comment ID): 637704

Concern Statement: Lower reservoir pools would give USACE more flexibility with storage and release permitting real reservoir unbalancing in future years. Lower pools also have the crucial advantage of reducing the need for high summer flood-control releases that too often have flooded tern and plover nests.

Response: Lowering the base of the annual flood control zone does provide additional flood control storage. However, since that target level stays the same from year to year, runoff received during a given year still needs to be evacuated from the reservoir system prior to the start of the next year's runoff season. Lower reservoir levels have negative impacts on other authorized purpose such as navigation, hydropower, and recreation. Changing target levels from year to year is not feasible given the uncertainty about runoff that will be received in a given year.

Comments (Comment ID): 637714, 641265

Concern Statement: The range among Alternatives 2–6 is inadequate in that there are significant differences between Alternative 2 and Alternatives 3–6. But among Alternatives 3–6 the differences are minimal.

Response: Alternatives 1 and 2 represent a different management approach than Alternatives 3–6 because the habitat goals and types described in Alternatives 1 and 2 were written in 2003, before the recent effects analysis. The habitat types and goals reflected in Alternatives 3–6 incorporate more recent guidance from USFWS and the results of the effects analysis. It is rational to predict the effects of the current course of action (the range of future implementation of the current BiOp is reflected by Alternatives 1 and 2) and compare these to new courses of action. This is a meaningful comparison; the no action alternative does not provide a useful comparison if it assumes the very existence of the plan being proposed. USACE believes it has examined a full spectrum of alternatives that represent the 2003 BiOp actions and actions based on results of the more recent effects analysis. Alternatives 3–6 represent substantially different means of achieving the objectives because, with the exception of Alternative 3, they all include a different re-occurring flow operation for endangered species. The impact analysis for Alternatives 3–6 show that the impacts vary widely depending on which resource is being examined. This further supports the notion that there is a substantial difference between these alternatives. Section 2.9 of the Final EIS provides a clear comparison of alternatives in terms of the species objectives, Affected Environment and Environmental Consequences and provides a description of how those factors were weighed in the decision. More-detailed comparisons of the alternatives in terms of species objectives are provide in Sections 3.3 and 3.4. USACE believes the analysis presented in Chapter 3 is sufficient for the public to compare the effects of the different alternatives especially considering the uncertainties regarding pallid sturgeon recruitment failure. The analysis presents what is known from the best available science and predicts the potential outcomes of the management actions based on what is currently known. A comprehensive SAMP has been developed to adjust these actions as more is learned in the future.

Comments (Comment ID): 640117, 644924, 645216, 645490, 640120, 640187, 644925

Concern Statement: USACE is encouraged to formulate a new alternative in the Final EIS that incorporates recovery actions that will: (1) reconnect the river to its floodplain, (2) restore wetlands, (3) provide quality habitat for self-sustaining populations of fish and wildlife, (4) incorporate BSNP Mitigation in all recovery actions, and (5) utilize natural processes for habitat restoration whenever possible.

Response: The actions in the EIS are designed to fulfill endangered species act responsibilities although a variety of fish and wildlife species would benefit as outlined in Chapter 3 of the EIS. Best available science at this time does not indicate that pallid sturgeon of any age are food limited or that floodplain connectivity would increase pallid spawning habitat. USACE coordinated with USFWS during development of Alternative 2 to identify criteria for clarification of the floodplain connectivity language from the 2003 BiOp. The 2003 BiOp did not contain numeric criteria for floodplain connectivity. USFWS provided these criteria in a Planning Aid Letter submitted to USACE on November 5, 2015. The criteria stated that the management action should maximize floodplain habitat by ensuring that 77,410 acres of connected floodplain are inundated at a 20 percent annual chance exceedance. This acreage amount was an interpretation, made in 2015, of the

language from the 2003 BiOp developed to inform alternatives development. USACE conducted HEC-GeoRAS mapping to determine the acres of existing floodplain connectivity in the lower Missouri River. This was the first time this type of an analysis had been done. The mapping results indicated that 147,650 acres of floodplain connectivity are currently present, not including the area of the main channel. Under each Alternative, it is assumed that normal operations combined with tributary inflow would result in floodplain connectivity of at least 77,410 acres as indicated by the mapping results described previously, thus no additional action would be required. This analysis should not be interpreted to indicate that floodplain connectivity has increased from 77,410 acres to 147,650 acres from 2003 to present. Only that current normal operations combined with tributary inflow are meeting numeric criteria for floodplain connectivity developed by USFWS in 2015.

As described in Section 2.8.4 of the EIS under the preferred alternative approximately 1,772 acres of additional land would be projected to be purchased in association with IRC habitat construction. As described in Section 2.5.4 of the EIS the land acquisition authority for mitigation of the construction of the BSNP is not being reassessed through this Management Plan and the total mitigation authority acres remain at 166,750 acres. USACE has acquired approximately 66,616 acres of the authorized 166,750 acres, nearly 40 percent. Land acquisition and habitat development under the BSNP mitigation authority is not limited to pallid sturgeon habitat and can include restoration of native vegetation, wetlands, bottomland forest, backwaters and other Missouri River habitats lost due to the BSNP. Appropriate vegetation and habitat types are determined on a site-specific basis. It is assumed that real-estate purchases for the 15-year implementation timeframe would continue to prioritize land that contributes to jeopardy avoidance, while still constituting appropriate acquisition and development under the WRDA authorities. The current budgetary priority is on ESA compliance rather than habitat acquisition and creation for non-listed species. If budgetary priorities change the necessary authorities and NEPA framework (the 2003 Supplemental EIS for BSNP Mitigation) are already in place to fully implement BSNP mitigation.

Comments (Comment ID): 640492, 641472

Concern Statement: The Draft EIS should include recovery actions that allow the river to resume a more natural state within selected areas such as on state and federally owned lands and lands acquired from willing sellers.

Response: The actions in the EIS are designed to fulfill endangered species act responsibilities although a variety of fish and wildlife species would benefit as outlined in Chapter 3 of the EIS. Best available science at this time does not indicate that pallid sturgeon of any age are food limited or that floodplain connectivity would increase pallid spawning habitat. USACE coordinated with USFWS during development of Alternative 2 to identify criteria for clarification of the floodplain connectivity language from the 2003 BiOp. The 2003 BiOp did not contain numeric criteria for floodplain connectivity. USFWS provided these criteria in a Planning Aid Letter submitted to USACE on November 5, 2015. The criteria stated that the management action should maximize floodplain habitat by ensuring that 77,410 acres of connected floodplain are inundated at a 20 percent annual chance exceedance. This acreage amount was an interpretation, made in 2015, of the language from the 2003 BiOp developed to inform alternatives development. USACE conducted HEC-GeoRAS mapping to determine the acres of existing floodplain connectivity in the lower Missouri River. This was the first time this type of an analysis

had been done. The mapping results indicated that 147,650 acres of floodplain connectivity are currently present, not including the area of the main channel. Under each Alternative, it is assumed that normal operations combined with tributary inflow would result in floodplain connectivity of at least 77,410 acres as indicated by the mapping results described previously, thus no additional action would be required. This analysis should not be interpreted to indicate that floodplain connectivity has increased from 77,410 acres to 147,650 acres from 2003 to present. Only that current normal operations combined with tributary inflow are meeting numeric criteria for floodplain connectivity developed by USFWS in 2015. Alternative 3 is designed to restore components of the ecosystem thought to be important to the three listed species based on best available science. Alternative 3 also includes a comprehensive SAMP designed to continually update the scientific knowledge base and incorporate this knowledge into management actions on the ground.

As described in Section 2.8.4 of the EIS under the preferred alternative approximately 1,772 acres of additional land would be projected to be purchased in association with IRC habitat construction. As described in Section 2.5.4 of the EIS the land acquisition authority for mitigation of the construction of the BSNP is not being reassessed through this Management Plan and the total mitigation authority acres remain at 166,750 acres. Comments (Comment ID): 640499, 640440, 641455

Concern Statement: The upper Mississippi River Habitat Rehabilitation Program has successfully conducted multiple large-scale projects that include the creation of islands, backwater areas, etc. and returned the river to a more natural state. These larger scale practices should be considered in the Missouri River so meaningful restoration can be accomplished. The upper Mississippi River Habitat Rehabilitation Program should be used as an example of agencies and stakeholders working together to make an ecologically relevant difference while meeting all needs and authorized purposes.

Response: The actions in the EIS are designed to fulfill endangered species act responsibilities although a variety of fish and wildlife species would benefit as outlined in Chapter 3 of the EIS. Best available science at this time does not indicate that pallid sturgeon of any age are food limited or that floodplain connectivity would increase pallid spawning habitat. Representative Quotes (Correspondence ID): 147
Comments (Comment ID): 640708

Concern Statement: USACE must pursue every opportunity to acquire available lands in the floodway and to remove or set back the levees in order to reduce flood risks.

Response: Levee setbacks have occurred on MRRP acquired lands in the past and they are an option in the future should floodplain connectivity or other levee setback benefit become necessary. However, the primary hypothesized benefit from floodplain connectivity is food production and it does not appear that pallid sturgeon of any size are food limited.

Representative Quotes (Correspondence ID): 163
Comments (Comment ID): 641276

Concern Statement: Level 1 and Level 2 actions should be prioritized to guide funding expenditures; the pallid sturgeon propagation and augmentation program should continue and lower river early life stage habitat construction should be implemented on a trial basis prior to full implementation. Additionally, habitat development should be undertaken on MRRP lands.

Response: Concur, this recommendation is consistent with the preferred alternative. The PSPAP is considered fundamental context to evaluating population level responses to management actions. The present redesign is intended to make it more efficient and relevant to management decisions.

Representative Quotes (Correspondence ID): 192
Comments (Comment ID): 641664

Concern Statement: The selected alternative must meet the eight authorized purposes. Insufficient time was allocated to the process of developing alternatives.

Response: The preferred alternative is consistent with supporting the eight authorized purposes. The alternatives were developed over a three-year period beginning with the effects analysis in 2016 which is considered to be sufficient time by USACE. All stages of alternatives development including the effects analysis were shared with MRRIC for input. The public comment period ranged from December 16 to April 24 providing another opportunity to provide input on alternatives.

Representative Quotes (Correspondence ID): 205
Comments (Comment ID): 642125

Concern Statement: The Nebraska Game and Parks Commission believes that a systematic plan of top-width widening for the entire channelized reach in Nebraska would provide huge positive economic benefits to the Missouri River system not considered in any of the alternatives presented in the Draft EIS.

Response: It is not clear that top-width widening of any scale would alleviate factors limiting pallid sturgeon recruitment. USACE has outlined a scaled approach that ultimately could lead to wider adoption of top-width widening or other actions if it is determined these actions would address ecosystem factors limiting pallid sturgeon recruitment. The effects analysis and the SAMP present the key uncertainties that challenge implementation decisions for the MRRP. They also detail the rationale and approach to developing the necessary supporting science so that management actions can be implemented and evaluated against expected outcomes with a reasonable expectation that the knowledge gained will contribute to improved understanding, better implementation decisions, and increased likelihood of achieving the program objectives over time. The AM framework provides a measured approach to implementation, recognizing that causal understanding and the development of management-response functions will be necessary to ensure that management actions taken will be effective. This strategy acknowledges the tradeoffs between knowledge and action, emphasizing the need for early investment in understanding so that long-term management prospects are improved. This strategy has the added benefits of reducing the risks of taking regrettable, expensive, and potentially irreversible actions that could have serious economic, social, and environmental impacts and ultimately hurt the prospects of species recovery.

Representative Quotes (Correspondence ID): 237
Comments (Comment ID): 643110

Concern Statement: The definition of piping plover nesting habitat should be expanded to include oxbows, sand spoil areas, alkaline lakes, and reservoir management areas. This would greatly increase the likelihood of meeting plover objectives at a reduced cost.

Response: As explained in Section 2.5.1.4 of the Draft EIS, USFWS recommended that USACE not include sandpit habitat management or habitat development in the navigation channel as management actions in this plan (USFWS 2015a). USFWS identified several issues that would need to be resolved to consider this a feasible management action including the reproductive potential of these areas, potential for high predation, habitat preferences and dispersal, forage availability, land acquisition, and feasibility of creation and maintenance (USFWS 2015a). This management action was eliminated from further consideration because it is not currently demonstrated to be as effective or efficient at meeting species objectives relative to other available management actions such as in-river construction of ESH and vegetation management on ESH (USACE 2012a). Although this action was eliminated from consideration in this EIS, USFWS has been working with MRRIC to pursue a pilot project with alternate funding (not through MRRP). The results of the pilot project could be evaluated through the AM process and incorporated into future management if deemed effective.

Representative Quotes (Correspondence ID): 107
Comments (Comment ID): 643827

Concern Statement: The potential for larval pallid sturgeon to drift out of the Missouri River (and into the Mississippi River) should not deter development of IRC habitats in the very lower portion of the Missouri River or even the Mississippi River.

Response: The preferred alternative does include the ability to construct IRC habitat in the very lower portion of the Missouri River. The MRRP ISP has already begun supporting the microchemistry and genetics studies that are the basis for understanding relations with the Mississippi River. Under Big Question 4 on drift dynamics there is a level 1 field study to assess free embryo transport to the Mississippi River. This study will estimate the number and survival of age-0 to juveniles hatched in the Missouri that reach the Mississippi River relative to the number and survival of those that remain in the Missouri River. The SAMP is designed to be flexible and a modified geographic scope for IRC construction could be incorporated into management if needed in the future after a supplemental NEPA process is conducted.

Representative Quotes (Correspondence ID): 107
Comments (Comment ID): 643860

Concern Statement: USACE should identify and define actions which can be implemented immediately.

Response: As explained in the Draft and Final EIS the preferred alternative includes immediate implementation of IRC habitat construction and associated land purchases and habitat development, spawning habitat construction, continuation of propagation and stocking, construction of ESH, vegetation management, human restriction measures, predator management, and flow management to avoid take of birds.

Representative Quotes (Correspondence ID): 183
Comments (Comment ID): 643931

Concern Statement: USACE should commit to use other tools such as flows to meet MRRMP objectives even though it may take many years to clear the impediments to use flows to

restore the ecological function of the Missouri River. USACE should focus initial efforts in reaches where flood risk is the highest such as the reach below Fort Randall Dam and other previously identified reaches where pinch points and low-lying land are at risk.

Response: Actions outside of the preferred alternative, or selected alternative, are still available for implementation pending additional analysis and public involvement. USACE believes it has selected a reasonable set of initial actions to be implemented over a 15-year timeframe that address priority hypotheses and the species objectives. It would not be appropriate to include the myriad of potential actions in the selected alternative if it is not reasonably foreseeable that they would need to be implemented. The alternative is designed to give the public, Tribes, stakeholders, and other agencies reasonable expectations of what will be implemented rather than include a myriad of potential actions that may or may not be implemented under unfettered discretion of USACE to implement. The AM process allows for new actions, not within the selected alternative, to be implemented following a transparent discourse with the Tribes, public, stakeholders, and other agencies and supplemental NEPA analysis if needed.

Representative Quotes (Correspondence ID): 183
Comments (Comment ID): 643936

Concern Statement: The MRRMP fails to benefit pallid sturgeon in Montana within a realistic timeframe. In Montana, what does this plan recover, what habitats are improved, and what USACE-caused impacts that threaten this species with extinction are eliminated?

Response: Modifications at Fort Peck Dam were considered during alternatives formulation. Please see Section 2.5.21 of the Final EIS for a detailed discussion of the status of actions at Fort Peck Dam. In recognition of the scientific uncertainty surrounding Fort Peck flow adjustments, USACE agreed to formulate test flows from Fort Peck and an AM framework for their implementation during formal ESA Section 7 consultation on this plan. Studies under the framework may include additional drift studies, tracking of fish and documentation of spawning locations, telemetry evaluations and methodology improvements, risk analysis, and engineering studies. Implementation of an identified hydrograph to test hypotheses would be considered; however, depending on the specifics of the test hydrograph, may be outside the scope of this EIS.

Representative Quotes (Correspondence ID): 191
Comments (Comment ID): 644045

Concern Statement: The preclusion from consideration of modifications to Fort Peck Dam to address the downstream impacts of hypolimnetic dam discharge severely limit the list of possible management actions in Montana that would benefit pallid sturgeon and their habitats.

Response: Modifications at Fort Peck Dam were considered during alternatives formulation. Please see Section 2.5.21 of the Final EIS for a detailed discussion of the status of actions at Fort Peck Dam. In recognition of the scientific uncertainty surrounding Fort Peck flow adjustments, USACE agreed to formulate test flows from Fort Peck and an AM framework for their implementation during formal ESA Section 7 consultation on this plan. Studies under the framework may include additional drift studies, tracking of fish and documentation of spawning locations, telemetry evaluations and methodology improvements, risk analysis, and engineering studies. Concern Statement: Along the Missouri River from St Louis, Missouri to Montana, there are different areas that deal with different segments and different circumstances. These areas could be divided up into lengths along the river and the habitat could be enhanced in different ways, for the different circumstances.

Response: Site-specific characteristics are factored into each site-specific project planning process.

Representative Quotes (Correspondence ID): 225
Comments (Comment ID): 644420

Concern Statement: The flow hypotheses are incomplete with regard to the pallid sturgeon unless additional sediment load is placed back into the system from that which is currently trapped behind the Mainstem dams in their reservoirs.

Response: There currently is no scientific evidence that a lack of sediment in the lower river is inhibiting recruitment of pallid sturgeon and this was not identified as a priority hypothesis at this time. Sediment transport issues are the subject of the Lewis and Clark sediment management study funded by the MRRP (available at www.moriverrecovery.org). Phase II of this study is ongoing. In the future, it is likely that MRRP will continue to fund sediment management studies where sediment issues intersect with ESA issues.

Representative Quotes (Correspondence ID): 222
Comments (Comment ID): 644786

Concern Statement: None of the alternatives, including the preferred alternative, address the sediment starved river due to retention behind the Mainstem dams, the spawning affects related to that trapped material, and the impact on the species.

Response: There currently is no scientific evidence that a lack of sediment in the lower river is inhibiting recruitment of pallid sturgeon and this was not identified as a priority hypothesis at this time. Sediment transport issues are the subject of the Lewis and Clark sediment management study funded by the MRRP (available at www.moriverrecovery.org). Phase II of this study is ongoing. In the future, it is likely that MRRP will continue to fund sediment management studies where sediment issues intersect with ESA issues.

Representative Quotes (Correspondence ID): 222
Comments (Comment ID): 644823, 644830

Concern Statement: The differences in spawning habitat construction are significant and unexplained. Since spawning habitat creation has not been sufficiently studied, it is reasonable to consider an alternative in which active AM, including Level 1 and 2 studies, is first used to assess the specifications of spawning habitat construction and to determine whether the action would have positive impacts on the pallid sturgeon. An alternative using a middle-ground approach to spawning habitat construction would potentially be more effective than either including or excluding spawning habitat construction.

Response: As a point of clarification, the preferred alternative does include Level 1 and Level 2 studies prior to full construction of spawning habitat. This is explained in the SAMP.

Alternatives 1 and 2 are based on the 2003 Biological Opinion which did not include spawning habitat. Alternatives 3–6 are based on the results of the recent effects analysis which identified spawning habitat as a potential limiting factor.

Representative Quotes (Correspondence ID): 223
Comments (Comment ID): 644945

Concern Statement: There is a huge cost difference between the alternatives, which leaves room for middle-ground alternatives. There is clearly room for additional reasonable and feasible alternatives to create early life stage habitat with costs that fall between the ranges of Alternative 2 and Alternatives 3–6.

Response: The amount of early life stage habitat (Shallow Water Habitat) under Alternatives 1 and 2 are a reflection of acreage goals in the 2003 Biological Opinion. The amount of early life stage habitat in Alternatives 3–6 are a reflection of what is needed for determining effectiveness of the IRC action and additional amounts of IRC that would be built if the Management Action is deemed effective. Alternatives 1 and 2 represent a different management approach than Alternatives 3–6 because the habitat goals and types described in Alternatives 1 and 2 were written in 2003, before the recent effects analysis. The habitat types and goals reflected in Alternatives 3–6 incorporate more recent guidance from USFWS and the results of the effects analysis.

Representative Quotes (Correspondence ID): 223
Comments (Comment ID): 644948

Concern Statement: Spawning habitat construction, spawning cue releases, and IRC for early life stage habitat construction need further study before they can be effectively implemented. USACE should propose at least one alternative that contains the most effective actions of Alternative 2 but also incorporates active AM and Level 1 and Level 2 studies on these topics.

Response: The most effective actions for the birds in Alternative 2 include the very same actions that are in the preferred alternative except with a different amount of ESH construction. It is uncertain which actions from Alternative 2 are “most effective” for pallid sturgeon, but most of the actions in Alternative 2 have been implemented over the past 14 years with no improvement in recruitment. USACE believes that the initial set of actions identified in Alternative 3 coupled with the SAMP represent the best chance for improving management for the listed species. They are based on the best available science and include a structured process to reduce uncertainty and introduce new management actions as necessary. USACE has completed formal ESA consultation and received a finding of non-jeopardy from USFWS in their Biological Opinion.

Representative Quotes (Correspondence ID): 223
Comments (Comment ID): 644953

Concern Statement: Increasing sediment transport downstream from the impounded section of the Missouri River needs to be included in the Draft MRRMP-EIS alternatives. It should also be evaluated in the Final EIS with regards to potential benefits to the listed species and to overall ecosystem health.

Response: There currently is no scientific evidence that a lack of sediment in the lower river is inhibiting recruitment of pallid sturgeon and this was not identified as a priority hypothesis at this time. Sediment transport issues are the subject of the Lewis and Clark sediment management study funded by the MRRP (available at

www.moriverrecovery.org). Phase II of this study is ongoing. In the future, it is likely that MRRP will continue to fund sediment management studies where sediment issues intersect with ESA issues.

Representative Quotes (Correspondence ID): 206
Comments (Comment ID): 645133

Concern Statement: USACE should re-work the Draft EIS alternatives analysis, develop a greater range of alternatives, revise the cost of and add the new SAMP to it, develop a more specific Purpose and Need Statement, and reduce the over-reaching of the Human Considerations impacts.

Response: USACE believes the current range of alternatives represents the full spectrum of alternatives that could be taken in relation to the 2003 BiOp and in relation to the recent effects analysis. The cost of alternative 2 is largely driven by required ESH and SWH acreages included in the 2003 Biological Opinion. The SAMP is based on hypotheses in the effects analysis that are rooted in the best available science. The AM framework for Alternatives 1 and 2 would continue to follow the AM framework as described in the MRRP AM Framework (USACE, 2011), SWH AM Plan (USACE, 2012), and ESH AM Plan (USACE, 2011). The primary goal for the alternatives is to meet species objectives as described in the Purpose and Need Chapter of the EIS. USACE believes it has selected the plan that achieves species objectives while causing the least amount of impacts to the range of river uses. Alternatives 1 and 2 represent a different management approach than Alternatives 3–6 because the habitat goals and types described in Alternatives 1 and 2 were written in 2003, before the recent effects analysis. The habitat types and goals reflected in Alternatives 3–6 incorporate more recent guidance from USFWS and the results of the effects analysis.

Representative Quotes (Correspondence ID): 179
Comments (Comment ID): 645200

Concern Statement: Levee setbacks and a riparian corridor along the full length of the Mainstem river would provide habitat, connectivity to the floodplain and prevention of fragmentation of habitat. This approach would also provide significant acres of adjacent lands capable of holding excess water and of providing infiltration and evaporation - all contributing to Flood Risk Reduction.

Response: Levee setbacks have occurred on MRRP acquired lands in the past and they are an option in the future should floodplain connectivity or other levee setback benefit become necessary. However, the primary hypothesized benefit from floodplain connectivity is food production and it does not appear that pallid sturgeon of any size are food limited.

Representative Quotes (Correspondence ID): 179
Comments (Comment ID): 645217

Concern Statement: USFWS outstanding concept of the development of habitat sites distributed along the Missouri River, giving a diversity of habitats for all species, should be incorporated in the Draft EIS.

Response: Comment noted. The comment appears to be in reference to a specific concept not introduced into the planning process by USFWS either through their role as a Cooperating Agency on the EIS or through ESA formal consultation.

Representative Quotes (Correspondence ID): 179
Comments (Comment ID): 645226

Concern Statement: USACE and USFWS are requested to develop and incorporate into the Draft EIS a pilot project utilizing beach nourishment technologies to transfer sediment from behind a Mainstem dam into a downstream reach of the Missouri River. Stream bed degradation in certain reaches of the Missouri River below the dams is an issue that must be addressed in the coming decades.

Response: There currently is no scientific evidence that a lack of sediment in the lower river is inhibiting recruitment of pallid sturgeon and this was not identified as a priority hypothesis at this time. Sediment transport issues are the subject of the Lewis and Clark sediment management study funded by the MRRP (available at www.moriverrecovery.org). Phase II of this study is ongoing. In the future, it is likely that MRRP will continue to fund sediment management studies where sediment issues intersect with ESA issues.

Representative Quotes (Correspondence ID): 221
Comments (Comment ID): 645297

Concern Statement: The preferred alternative would benefit from inclusion of the following management actions: (1) creation of IRC or other hydraulic roughness in the upper river section, (2) improve anoxic conditions at reservoir arms which could serve as nursery habitat for the pallid sturgeon, and (3) modifications at Fort Peck to support flows, warmer temperatures, and hydraulic roughness.

Response:

- (1) Increasing channel “roughness” in the upper river does not appear to be a viable management hypothesis because the reach of the Missouri River between Fort Peck and Lake Sakakawea is already unchannelized and any drift distance gained from mechanical channel modifications in this reach would be negligible in context of the already relatively natural channel. Any channel roughness that could be added would likely not be enough to overcome the lack of drift distance. Improvement of conditions via drawdown of Lake Sakakawea was deemed not viable given the levels of drawdown that would need to occur and the uncertainty whether the drawn-down lake pool would be hospitable to settling pallid larvae.
- (2) Anoxic conditions in the reservoir is a function of reduced river velocities and the concentration of fine particulate organic material with high microbial respiration (Guy et al, 2015). Anoxic sediments will continue to form even if existing anoxic sediment were to be removed. Removal of sediment from the headwaters of Lake Sakakawea and/or increasing dissolved oxygen in headwaters using air diffusers or similar methods is not feasible given the scale and cost of effort and the uncertainty whether this could actually be accomplished and whether it would have any benefit to pallid sturgeon if it were.
- (3) Modifications at Fort Peck Dam were considered during alternatives formulation. Please see Section 2.5.21 of the Final EIS for a detailed discussion of the status of actions at Fort Peck Dam. In recognition of the scientific uncertainty surrounding Fort Peck flow adjustments, USACE agreed to formulate test flows from Fort Peck and an AM framework for their implementation during formal ESA Section 7 consultation on this plan. Studies under the framework may include additional drift studies, tracking of fish and documentation of spawning locations, telemetry evaluations and methodology improvements, risk analysis, and engineering studies. Implementation of an identified hydrograph to test hypotheses would be considered; however, depending on the specifics of the test hydrograph, may be outside the scope of this EIS.

Representative Quotes (Correspondence ID): 238
Comments (Comment ID): 645325

Concern Statement: Reservoir reallocation of uses is needed to support implementation of the selected alternative; a basin wide approach could be taken to regulate flows throughout the basin. Without reallocation of reservoir storage, successful implementation of flow modifications under the alternatives outlined in the Draft EIS are unlikely to occur.

Response: There is very little scientific evidence to support flow modifications of any magnitude or frequency for pallid sturgeon including the flows called for in the 2003 Biological Opinion. USFWS acknowledged this uncertainty and urged USACE to implement the 2003 BiOp using a science and adaptive management approach. USACE believes the newly updated science and adaptive management approach that consists of research, monitoring of natural flow events, and potential test flows is more likely to be successful than prescribing and implementing flows based on little scientific knowledge. As described in Chapter 3 of the EIS, as a whole, the population of pallid sturgeon appears to be stable because of the supplemental stocking by the PSCAP but is not self-sustaining because natural recruitment is apparently not occurring. Stocked pallid sturgeon feed and grow successfully in all RPMAs where they have been stocked and have begun to reach sexual maturity in the past few years and spawning is occurring and has been documented. USACE has outlined a scaled approach that ultimately could lead to reservoir and/or flow modification if it is determined these actions would address ecosystem factors limiting pallid sturgeon recruitment. The effects analysis and the SAMP present the key uncertainties that challenge implementation decisions for the MRRP. They also detail the rationale and approach to developing the necessary supporting science so that management actions can be implemented and evaluated against expected outcomes with a reasonable expectation that the knowledge gained will contribute to improved understanding, better implementation decisions, and increased likelihood of achieving the program objectives over time. The AM framework provides a measured approach to implementation, recognizing that causal understanding and the development of management-response functions will be necessary to ensure that management actions taken will be effective. This strategy acknowledges the tradeoffs between knowledge and action, emphasizing the need for early investment in understanding so that long-term management prospects are improved.

Comments (Comment ID): 645330

Concern Statement: What research is proposed to address the issue of hybridization of pallid and shovelnose sturgeon?

Response: Genetic testing is done for sampled sturgeon and part of the spawning habitat hypothesis is that manipulating spawning substrates will increase aggregation and reduce hybridization and improve reproductive success. Improvements to address genetic concerns (e.g., maintaining genetic variation similar to the natural population minimizing threats of hybridization, disease, stocking size etc.) are being pursued collaboratively with USFWS and others to be consistent with the Basin-Wide stocking and augmentation plan.

Comments (Comment ID): 645541

Concern Statement: More research should be conducted on the hypothesis that the velocity and turbulence of navigation channel may be fatal to free embryos of pallid sturgeon in the lower river.

Response: Addressing the turbulence and velocity hypothesis is part of addressing Big Question 4 in the SAMP: Drift Dynamics: Can naturalization of the flow regime or channel reconfiguration (alone or in combination) contribute to decreased direct mortality and increased interception of free embryos into supporting habitats. Research is scheduled to be conducted to determine the survival of free embryos related to measures of fluid stress, including turbulent intensity and shear.

Representative Quotes (Correspondence ID): 242
Comments (Comment ID): 645552

Concern Statement: USACE is urged to implement recovery actions that return low velocity areas to the river. This type of aquatic habitat would provide long-term, large, beneficial impacts to fish and wildlife. Further, USACE is encouraged to implement recovery actions that restore needed habitat for the 51 of 67 native fish species that are rare or declining on the river; this can be accomplished through restoring slow and shallow water habitat, levee setbacks, and river widening projects. Other federally protected species should also be considered.

Response: The IRC habitat construction and associated land acquisition are consistent with adding low-velocity areas to the river although the IRC concept also incorporates depth and interception hydraulics.

Representative Quotes (Correspondence ID): 242
Comments (Comment ID): 645568

Concern Statement: More research needs to be conducted to determine if the high turbulence of the navigation channel is fatal to free drifting embryos.

Response: Addressing the turbulence and velocity hypothesis is part of addressing Big Question 4 in the SAMP: Drift Dynamics: Can naturalization of the flow regime or channel reconfiguration (alone or in combination) contribute to decreased direct mortality and increased interception of free embryos into supporting habitats. Research is scheduled to be conducted to determine the survival of free embryos related to measures of fluid stress, including turbulent intensity and shear.

Representative Quotes (Correspondence ID): 242
Comments (Comment ID): 645841

Concern Statement: USACE should consider an alternative in which the average ESH construction in build years falls between the 3,546 acres of Alternative 2 and the 391 acres constructed in Alternative 3–6.

Response: The ESH acres under Alternatives 3–6 meet the piping plover objectives. There is no need at this point to look for ESH acreages that fall in-between Alternative 2 and Alternatives 3–6.

Representative Quotes (Correspondence ID): 223
Comments (Comment ID): 645990

Concern Statement: Increasing channel capacity in the river would benefit flow-based management actions and is a necessary prerequisite to any use of flow as an action.

Response: The SAMP outlines a comprehensive and structured approach for conducting pallid sturgeon science and incorporating the results into future management. Real-time careful consideration of precipitation forecasts and resulting downstream tributary inflow would be necessary in order to plan releases to avoid flooding potential downstream of Gavins Point Dam. However, since this release is above current channel capacity in the Fort Randall reach some impacts to private lands would likely occur. In addition, the ability to mitigate impacts by using downstream inflow forecasts is limited by the travel time downstream of Gavins Point Dam and the reduced forecast accuracy 5 to 7 days in the future. USACE has sought to minimize this impact as much as possible in the very selection of the preferred alternative. USACE will continue to effectively strategize how to minimize the impacts over the next 9 years should this test be required. The single year impacts of a partial or fully implemented pulse would be expected within range of the years where a pulse was implemented in Alternative 6. It would also be advisable to avoid this release when System storage levels are close to navigation preclusions to avoid impacts to navigation.

Representative Quotes (Correspondence ID): 206
Comments (Comment ID): 646270

Concern Statement: The location of spawning and rearing habitat for pallid sturgeon should be located to minimize impacts to existing water intakes.

Response: Each site-specific construction project will be designed to avoid or minimize impacts to water intakes and other infrastructure.

Representative Quotes (Correspondence ID): 107
Comments (Comment ID): 646288

Concern Statement: Flow releases should contain accompanying sediment as clear water releases have not demonstrated any benefits to pallid sturgeon.

Response: Sediment redistribution as a management action was considered and discussed in Section 2.5.1.14 of the Draft EIS. Based on the results of Phase I of the Lewis and Clark Sediment Management Study, this action was eliminated from consideration in the Draft EIS because its effectiveness at contributing towards the species objectives and implementation feasibility has not been demonstrated. Phase II of the Sediment Study is ongoing and the results of that study would be evaluated through the process established in the SAMP.

Representative Quotes (Correspondence ID): 222
Comments (Comment ID): 644786

Concern Statement: USACE should develop a new management action for inclusion with the appropriate alternatives that modifies the navigation channel below Sioux Falls to have a more natural cross-section to benefit pallid sturgeon.

Response: Since 2003, USACE has constructed numerous projects on the lower river to increase shallow water habitat and to provide habitats lost from the BSNP. The preferred alternative does include construction of IRC habitats which involve modifying the channel to potentially improve interception of free embryos and foraging and food producing habitat for young of year sturgeon.

Representative Quotes (Correspondence ID): 162
Comments (Comment ID): 641212

Concern Statement: USACE should create a new management action that would lower March 1st storage targets and reduce navigation service levels to provide greater operational flexibility.

Response: Lowering the base of the annual flood control zone does provide additional flood control storage. However, since that target level stays the same from year to year, runoff received during a given year still needs to be evacuated from the reservoir system prior to the start of the next year's runoff season. Lower reservoir levels have negative impacts on other authorized purpose such as navigation, hydropower, and recreation. Changing target levels from year to year is not feasible given the uncertainty about runoff that will be received in a given year.

Representative Quotes (Correspondence ID): 162
Comments (Comment ID): 641264

Concern Statement: A new management action element should be created and aligned with the appropriate alternatives that terminates barge traffic along the stretch of the Missouri River that borders Iowa and restore the natural course of the river to improve habitat conditions for the least tern, piling plover and pallid sturgeon.

Response: The authority to terminate barge traffic on the Missouri River rests with Congress rather than USACE.

Representative Quotes (Correspondence ID): 190
Comments (Comment ID): 641582

Concern Statement: To support improved flood control on the Missouri River during MRRMP implementation, USACE should develop a management action for inclusion with all alternatives that would maintain reservoirs at 46.8 MAF on March 1, which would also benefit the bird species of concern.

Response: Lowering the base of the annual flood control zone does provide additional flood control storage. However, since that target level stays the same from year to year, runoff received during a given year still needs to be evacuated from the reservoir system prior to the start of the next year's runoff season. Lower reservoir levels have negative impacts on other authorized purpose such as navigation, hydropower, and recreation. Changing target levels from year to year is not feasible given the uncertainty about runoff that will be received in a given year.

Representative Quotes (Correspondence ID): 179
Comments (Comment ID): 645220

Concern Statement: USACE should create an alternative that requires barges to be shallow draft vessels allowing for shallower waters in the channel for spawning habitat construction.

Response: USACE does not have the authority to require use of shallow draft vessels.

Representative Quotes (Correspondence ID): 179
Comments (Comment ID): 645225

Concern Statement: A new alternative should be developed to include results of all science performed since 2003 with modified costs.

Response: Alternatives 3–6 were developed using the Effects Analysis which represents the best available science on the three listed species according to USFWS.

Representative Quotes (Correspondence ID): 81
Comments (Comment ID): 636790

Concern Statement: The range of alternatives is insufficient because a reasonable alternative could fall between Alternative 2 and Alternatives 3–6.

Response: The habitat types and goals reflected in Alternatives 3–6 incorporate more recent guidance from USFWS and the results of the effects analysis. It is rational to predict the effects of the current course of action (the range of future implementation of the current BiOp is reflected by Alternatives 1 and 2) and compare these to new courses of action. This is a meaningful comparison; the no action alternative is meaningless if it assumes the very existence of the plan being proposed. USACE believes it has examined a full spectrum of alternatives that represent the 2003 BiOp actions and actions based on results of the more recent effects analysis. Alternatives 3–6 represent substantially different means of achieving the objectives because, with the exception of Alternative 3, they all include a different re-occurring flow operation for endangered species. The impact analysis for Alternatives 3–6 show that the impacts vary widely depending on which resource is being examined. This further supports the notion that there is a substantial difference between these alternatives. USACE believes it has considered a range of alternatives and fully evaluated those that were determined to be reasonable. Although there could be other alternatives or variations of alternatives that could be assessed, an agency is not required to consider every potential permutation, but must consider a sufficient number covering the spectrum of the alternatives. USACE believes it has met this requirement. See generally 46 Fed. Reg. 18026 (March 23, 1981) as amended; question 1b.

Comments (Comment ID): 645216

Concern Statement: At the very least, a dam-removal alternative should be included, for baseline analysis of a full range of opportunities for restoration of water temperature needed for sturgeon reproduction in the Final EIS.

Response: Congressional authorization would be required to remove a dam. USACE feels it has examined a full range of alternatives and has identified an alternative that meets species objectives while minimizing impacts to other river interests. Therefore; a thorough examination of dam removal is not necessary at this point.

Representative Quotes (Correspondence ID): 232
Comments (Comment ID): 645481

Concern Statement: Riverine fish species in the Missouri River are adapted to warm, turbid waters. Any adjustments to Fort Peck should also include considerations for their life cycle needs including turbidity.

Response: Management actions concerning Fort Peck Dam and immediately downstream were not selected due to the high level of uncertainty regarding their feasibility to achieve desired biological, hydrological, or physical results and documented issues regarding their technical feasibility. In recognition of the scientific uncertainty surrounding Fort Peck flow adjustments, USACE agreed to formulate test flows from Fort Peck and an AM framework for their implementation during formal ESA Section 7 consultation on this plan. Studies under the framework may include additional drift studies, tracking of fish and documentation of spawning locations, telemetry evaluations and methodology improvements, risk analysis, and engineering studies. Implementation of an identified hydrograph to test hypotheses would be considered; however, depending on the specifics of the test hydrograph, may be outside the scope of this EIS.

AL5000 *Alternatives: Alternatives Considered but Eliminated from the Analysis*

Concern Statement: Changes in flow without enhancing the sediment load have no value and are a waste of precious water in the system.

Response: Sediment redistribution as a management action was considered and discussed in Section 2.5.1.14 of the Draft EIS. Based on the results of Phase I of the Lewis and Clark Sediment Management Study, this action was eliminated from consideration in the Draft EIS because its effectiveness at contributing towards the species objectives and implementation feasibility has not been demonstrated. Phase II of the Sediment Study is

ongoing and the results of that study would be evaluated through the process established in the SAMP.

Representative Quotes (Correspondence ID): 34
Comments (Comment ID): 628339

Concern Statement: USFWS and USACE should not confine the geographic scope for the birds to the Mainstem Missouri River only, but also consider other habitat (i.e., non-ESH habitat, and alkali lakes) to assist in achieving their goals. Many areas could be used for habitat development including meander scars, alkaline lakes, deltas, oxbows, and sand pits.

Response: USACE considered “Off-Channel” habitat creation and mechanical creation of hydrologically connected non-ESH habitat on Missouri River segments as part of alternatives development. This management action was eliminated from further consideration because it is not currently demonstrated to be as effective or efficient at meeting species objectives relative to other available management actions such as in-river construction of ESH and vegetation management on ESH. Although this action was eliminated from consideration in the Draft EIS, USFWS has expressed a willingness to pursue funding for a pilot project. This funding would not be through the USACE MRRP; however, the results of any pilot project could be evaluated under the SAMP. As stated in the SAMP, long-term changes off-river affecting Missouri River populations may require adjustments to target criteria or objectives. The AM process would incorporate the results of future metapopulation modeling as it becomes available in order to improve management decisions.

Representative Quotes (Correspondence ID): 107, 212
Comments (Comment ID): 644440, 641729

Concern Statement: Where are provisions for designation of critical habitat for the endangered pallid sturgeon; for unbalanced reservoirs to address the situation at a particular reservoir; and for the application of the best science currently available? Perhaps having unbalanced reservoirs as a management tool in the Missouri River Mainstem Reservoir System Master Water Control Manual is adequate, but perhaps not.

Response: Designation of pallid sturgeon critical habitat is not within the jurisdiction of USACE and therefore outside the scope of the proposed action. The effects analysis on which the Draft EIS was based gave consideration to all potential hypotheses related to pallid sturgeon limiting factors. The hypotheses were ranked through a panel of experts as to those most important to the species and the final set of management hypotheses formed the basis for the development of alternatives. However, the adaptive management process allows for returning to hypotheses that were filtered out should new information provide a reason to do so.

Representative Quotes (Correspondence ID): 81
Comments (Comment ID): 636788

Concern Statement: Reservoir unbalancing should be considered as a method to manage tern and plover nesting habitat along reservoir shorelines.

Response: A reservoir water level management action to contribute towards piping plover objectives was assessed by modeling an unbalancing of Lake Oahe. Modeling indicated that this action resulted in little additional available habitat over the POR. Bird population models showed that although this action contributed to bird populations on Lake Oahe, it

resulted in a corresponding negative effect on the bird population at Lake Sakakawea due to higher reservoir levels. As a result, this management action was eliminated from further consideration because it was not effective at contributing to the bird habitat targets and in turn the species objectives. Under all alternatives, the reservoir unbalancing included in the existing Master Manual would not be implemented. Experience has shown that storing water in the annual flood control zone, particularly at Lake Oahe, as the current criteria requires in order to implement unbalancing is undesirable due to flood control impacts.

Comments (Comment ID): 637705

Concern Statement: CMEPC supports a slightly revised Draft EIS preferred alternative, the addition of more off-channel, non-ESH work for plovers. Further, CMEPC believes that if the goal is to recover the species, it is imperative that for a societal economic as well as a species impact this work must be considered and implemented unless the science proves the benefits are not as robust as many believe they will be.

Response: USACE considered “Off-Channel” habitat creation and mechanical creation of hydrologically connected non-ESH habitat on Missouri River segments as part of alternatives development. This management action was eliminated from further consideration because it is not currently demonstrated to be as effective or efficient at meeting species objectives relative to other available management actions such as in-river construction of ESH and vegetation management on ESH. Although this action was eliminated from consideration in the Draft EIS, USFWS has expressed a willingness to pursue funding for a pilot project. This funding would not be through the USACE MRRP; however, the results of any pilot project could be evaluated under the SAMP. As stated in the SAMP, long-term changes off-river affecting Missouri River populations may require adjustments to target criteria or objectives. The AM process would incorporate the results of future metapopulation modeling as it becomes available in order to improve management decisions.

Comments (Comment ID): 640654

Concern Statement: Lower pools also produce lower river flood damage reductions, and I hope you will consider an alternative that incorporates a lower storage target and navigation service levels, better unbalancing, and overall better management of pools for terns and plovers and other wildlife benefits.

Response: USACE conducted a separate study of potential habitat enhancements on the Mainstem reservoirs. The purpose of the Draft Study of Potential Least Tern and Piping Plover Habitat Enhancement on the Reservoirs of the Missouri River Mainstem Reservoir System (Reservoir Study) is to identify potential habitat enhancement opportunities on reservoir segments in order to provide habitat for the least tern and piping plover. It examined broad feasibility of providing reservoir habitat and summarized findings on potential habitat creation opportunities. The study evaluated 149 sites for potential habitat enhancement on the reservoirs. The Reservoir Study recommended that the priority for mechanical habitat creation efforts should remain focused on the current riverine creation efforts, and not in the reservoirs. This conclusion was based on the multiple uncertainties and risks identified, including inundation, increased incidental take, excessive cost compared to other proven habitat creation options, infrequent availability for use by the birds, biological benefit to the birds, potential exacerbated

predation, and maintenance. The Draft EIS used the results of this study in evaluated a management action that considered creation of least tern and piping plover habitat on reservoirs, which was dismissed from consideration because of the rationale presented in the Reservoir Study.

A reservoir water level management action to contribute towards piping plover objectives was assessed by modeling an unbalancing of Lake Oahe. Modeling indicated that this action resulted in little additional available habitat over the POR. Bird population models showed that although this action contributed to bird populations on Lake Oahe, it resulted in a corresponding negative effect on the bird population at Lake Sakakawea due to higher reservoir levels. As a result, this management action was eliminated from further consideration because it was not effective at contributing to the bird habitat targets and in turn the species objectives. Under all alternatives, the reservoir unbalancing included in the existing Master Manual would not be implemented. Experience has shown that storing water in the annual flood control zone, particularly at Lake Oahe, as the current criteria requires in order to implement unbalancing is undesirable due to flood control impacts.

Lowering the amount of carryover storage available in the System would diminish the System's ability to provide support to all the authorized purposes during an extended drought. In terms of providing more exposed habitat on the reservoirs, the exposed habitat that would be available after the top of the carryover zone was lowered would eventually become unusable as it becomes covered with vegetation. Therefore, there would be no habitat benefit in the long term.

Comments (Comment ID): 641266

Concern Statement: Sediment transfer is a way to restore habitat and function to the Missouri and Mississippi River ecosystems while maintaining storage capacity for flood control, reducing bank erosion, and minimizing impacts on other uses of the rivers.

Response: Sediment redistribution as a management action was considered and discussed in Section 2.5.1.14 of the Draft EIS. Based on the results of Phase I of the Lewis and Clark Sediment Management Study, this action was eliminated from consideration in the Draft EIS because its effectiveness at contributing towards the species objectives and implementation feasibility has not been demonstrated. Phase II of the Sediment Study is ongoing and the results of that study would be evaluated through the process established in the SAMP.

Representative Quotes (Correspondence ID): 193
Comments (Comment ID): 641678

Concern Statement: Because the Draft EIS does not differentiate between nests on riverine and reservoir shorelines except to document that most incidental take occurs on reservoir shorelines it is misleading the public, and the science, as to the true role of the reservoirs. It is possible reservoirs and the increased shore line habitat would be a benefit to piping plover. Water level management utilizing all reservoirs to reduce the instance of incidental take on Lake Oahe and Lake Sakakawea has been adequately addressed in the Draft EIS or the Draft SAMP.

Response: USACE conducted a separate study of potential habitat enhancements on the Mainstem reservoirs. The purpose of the Draft Study of Potential Least Tern and Piping Plover Habitat Enhancement on the Reservoirs of the Missouri River Mainstem

Reservoir System (Reservoir Study) is to identify potential habitat enhancement opportunities on reservoir segments in order to provide habitat for the least tern and piping plover. It examined broad feasibility of providing reservoir habitat and summarized findings on potential habitat creation opportunities. The study evaluated 149 sites for potential habitat enhancement on the reservoirs. The Reservoir Study recommended that the priority for mechanical habitat creation efforts should remain focused on the current riverine creation efforts, and not in the reservoirs. This conclusion was based on the multiple uncertainties and risks identified, including inundation, increased incidental take, excessive cost compared to other proven habitat creation options, infrequent availability for use by the birds, biological benefit to the birds, potential exacerbated predation, and maintenance. The Draft EIS used the results of this study in evaluating a management action that considered creation of least tern and piping plover habitat on reservoirs, which was dismissed from consideration because of the rationale presented in the Reservoir Study.

Comments (Comment ID): 643857

Concern Statement: As the result of ongoing research, it appears there may be potential for survival/recruitment of larval pallid sturgeon within the Missouri River below Fort Peck Dam (Ryan Wilson. pers. comm. 2017). USFWS encourages consideration of MRRP actions within that reach of the Missouri River, pending the additional information and subsequent review.

Response: Modifications at Fort Peck Dam were considered during alternatives formulation. Please see Section 2.5.21 of the Final EIS for a detailed discussion of the status of actions at Fort Peck Dam. In recognition of the scientific uncertainty surrounding Fort Peck flow adjustments, USACE agreed to formulate test flows from Fort Peck and an AM framework for their implementation during formal ESA Section 7 consultation on this plan. Studies under the framework may include additional drift studies, tracking of fish and documentation of spawning locations, telemetry evaluations and methodology improvements, risk analysis, and engineering studies. Implementation of an identified hydrograph to test hypotheses would be considered; however, depending on the specifics of the test hydrograph, may be outside the scope of this EIS.

Representative Quotes (Correspondence ID): 183
Comments (Comment ID): 643933

Concern Statement: Implementation of Fort Peck management actions or a drawdown of Lake Sakakawea were not retained for alternative development in the Draft EIS due to the high level of uncertainty regarding their feasibility to achieve desired biological results and documented issues regarding their technical feasibility. The SAMP identifies a comprehensive framework for research and studies to address the uncertainty regarding the effectiveness of management actions for pallid sturgeon in the upper basin.

Response: Comment noted.

Representative Quotes (Correspondence ID): 191
Comments (Comment ID): 644087

Concern Statement: Realizing that the scope for the Draft EIS is 15 years, it is still dismaying that Big Question 5 Components 5 and 6 (studies with temperature control device at Fort Peck Dam) do not appear on the schedules for Proposed Implementation of Actions for the Upper Missouri River (Figure 4.4, 4 - 4, {1/344} in Volume 4 of the Draft EIS and in

the SAMP). If unnatural temperatures in Missouri River below Fort Peck Dam constitute take, how can USACE avoid jeopardy without addressing the effects of hypolimnetic withdrawals?

Response: Modifications at Fort Peck Dam were considered during alternatives formulation. Please see Section 2.5.21 of the Final EIS for a detailed discussion of the status of actions at Fort Peck Dam. In recognition of the scientific uncertainty surrounding Fort Peck flow adjustments, USACE agreed to formulate test flows from Fort Peck and an AM framework for their implementation during formal ESA Section 7 consultation on this plan. Studies under the framework may include additional drift studies, tracking of fish and documentation of spawning locations, telemetry evaluations and methodology improvements, risk analysis, and engineering studies. Implementation of an identified hydrograph to test hypotheses would be considered; however, depending on the specifics of the test hydrograph, may be outside the scope of this EIS. USFWS has determined the proposed action avoids a finding of jeopardy in its Final Biological Opinion (USFWS 2018).

Representative Quotes (Correspondence ID): 191
Comments (Comment ID): 644106

Concern Statement: USACE should develop alternative scenarios for flow releases of retained material in the reservoirs that increase sediment load downstream changing the flow cue strategy, or abandon all flow alternatives going forward.

Response: Sediment redistribution as a management action was considered and discussed in Section 2.5.1.14 of the Draft EIS. Based on the results of Phase I of the Lewis and Clark Sediment Management Study, this action was eliminated from consideration in the Draft EIS because its effectiveness at contributing towards the species objectives and implementation feasibility has not been demonstrated. Phase II of the Sediment Study is ongoing and the results of that study would be evaluated through the process established in the SAMP.

Representative Quotes (Correspondence ID): 222
Comments (Comment ID): 644804

Concern Statement: Adding sediment transport below Gavins Point Dam to the range of alternatives would help reduce shoreline erosion and degradation of the river bed. Removing sediment from the Niobrara River delta would help reduce flow constraints that hamper the ability to use flow as a tool to aid in species recovery.

Response: Sediment redistribution as a management action was considered and discussed in Section 2.5.1.14 of the Draft EIS. Based on the results of Phase I of the Lewis and Clark Sediment Management Study, this action was eliminated from consideration in the Draft EIS because its effectiveness at contributing towards the species objectives and implementation feasibility has not been demonstrated. Phase II of the Sediment Study is ongoing and the results of that study would be evaluated through the process established in the SAMP.

Representative Quotes (Correspondence ID): 206
Comments (Comment ID): 645134

Concern Statement: A low summer flow management action should be included in the range of alternatives because it resembles a more natural flow regime.

Response: A low summer flow management action was included in Alternative 2 and therefore was included within the range of alternatives.

Representative Quotes (Correspondence ID): 179
Comments (Comment ID): 645219

Concern Statement: The section of the EIS describing the reasons for not considering Fort Peck Dam removal should also state USACE does not have the authority to remove the dam.

Response: A statement has been added indicating that Congressional authorization would be required to remove Fort Peck dam.

Representative Quotes (Correspondence ID): 239
Comments (Comment ID): 645362

Concern Statement: Fort Peck management actions or a drawdown of Lake Sakakawea were not retained for alternative analysis due to the "high level of uncertainty" of the actions' ability to achieve the desired result. How can these actions be considered in any section of the SAMP if the actions were not analyzed in the EIS?

Response: Eliminating consideration of an action in the Draft EIS does not mean the action cannot still be considered within the scope of the SAMP. If implementation of the SAMP proceeds and the results of Level 1 or 2 studies or new information were to indicate that actions should be implemented that were not fully evaluated in this EIS, then additional NEPA compliance would likely be necessary prior to implementation of those actions.

Representative Quotes (Correspondence ID): 239
Comments (Comment ID): 645371

Concern Statement: A pilot project utilizing beach nourishment technologies to transfer sediment from past a Mainstem dam into a downstream reach of the Missouri River.

Response: Available information and analysis performed by USACE indicate that there is not a sand volume limitation for the formation of sandbars in the Gavins Point or Garrison Reach over the 50-year planning horizon for this project. This discussion is provided in Section 3.2 of the Final EIS. There currently is no scientific evidence that a lack of sediment in the lower river is inhibiting recruitment of pallid sturgeon and this was not identified as a priority hypothesis at this time. Sediment transport issues are the subject of the Lewis and Clark sediment management study funded by the MRRP (available at www.moriverrecovery.org). Phase II of this study is ongoing. In the future, it is likely that MRRP will continue to fund sediment management studies where sediment issues intersect with ESA issues.

Representative Quotes (Correspondence ID): 193
Comments (Comment ID): 641673

Concern Statement: Supporting appropriate releases from Fort Peck dam should be part of the Draft EIS alternative management actions, as the reach is currently part of the 2016 Biological Opinion. Resources should be dedicated to preserve this source population of pallid sturgeon. This includes investing in actions below Fort Peck to increase water temperatures, turbidity, and habitat to enhance relative drift distance.

Response: Modifications at Fort Peck Dam were considered during alternatives formulation. Please see Section 2.5.21 of the Final EIS for a detailed discussion of the status of

actions at Fort Peck Dam. In recognition of the scientific uncertainty surrounding Fort Peck flow adjustments, USACE agreed to formulate test flows from Fort Peck and an AM framework for their implementation during formal ESA Section 7 consultation on this plan. Studies under the framework may include additional drift studies, tracking of fish and documentation of spawning locations, telemetry evaluations and methodology improvements, risk analysis, and engineering studies. Implementation of an identified hydrograph to test hypotheses would be considered; however, depending on the specifics of the test hydrograph, may be outside the scope of this EIS.

Representative Quotes (Correspondence ID): 238
Comments (Comment ID): 645838

Concern Statement: USACE should consider purchase of off-channel habitat for both the piping plover and least tern which should be attainable at less cost than mechanical ESH creation or by flow releases.

Response: USACE considered “Off-Channel” habitat creation and purchase on Missouri River segments as part of alternatives development. This management action was eliminated from further consideration because it is not currently demonstrated to be as effective or efficient at meeting species objectives relative to other available management actions such as in-river construction of ESH and vegetation management on ESH. Although this action was eliminated from consideration in the Draft EIS, USFWS has expressed a willingness to pursue funding for a pilot project. This funding would not be through the USACE MRRP; however, the results of any pilot project could be evaluated under the SAMP. As stated in the SAMP, long-term changes off-river affecting Missouri River populations may require adjustments to target criteria or objectives. The AM process would incorporate the results of future metapopulation modeling as it becomes available in order to improve management decisions.

Representative Quotes (Correspondence ID): 194
Comments (Comment ID): 641711

Concern Statement: USACE should create an alternative that includes dam removal as a management action for the Final EIS.

Response: Congressional authorization would be required to remove a dam. USACE feels it has examined a full range of alternatives and has identified an alternative that meets species objectives while minimizing impacts to other river interests. Therefore; a thorough examination of dam removal is not necessary at this point.

Comments (Comment ID): 633681

AL800 *Alternatives: General Costs*

Concern Statement: The Draft MRRMP-EIS should provide the data to show that managing vegetation and predators on reservoir habitat areas is more expensive than management of (or continued creation of) ESH.

Response: USACE continues to believe that mechanically constructing ESH along with maintaining and/or creating new ESH through vegetation spraying is a viable means to meeting the tern and plover objectives of this Plan. The modeling indicates that persistence probability objectives will not be met without augmenting the ESH created by natural flows. Experience with constructing ESH and maintaining vegetation on natural

and constructed sandbars indicates these management actions are achievable and can be successful. It is true that in general the first 3-5 years are the most productive on constructed sandbars, however, this lifetime can be extended through vegetation management. As stated in the EIS, since monitoring of least tern and piping plover populations within the Missouri River began in 1986, approximately 80 percent of the total incidental take of piping plover eggs and chicks and 58 percent of least tern eggs and chicks were due to rising pool levels in reservoirs. The report cited in the EIS Draft Study of Potential Least Tern and Piping Plover Habitat Enhancement on the Reservoirs of the Missouri River Mainstem Reservoir System (USACE 2014b) presents additional detail related to the cost estimates and assumptions of creating and maintaining reservoir habitat.

Representative Quotes (Correspondence ID): 107
Comments (Comment ID): 643847

Concern Statement: The Final MRRMP-EIS should evaluate the annual and total costs of Management Plan and SAMP implementation in the context of the past amounts annually budgeted for the Missouri River Recovery Program and the Bank Stabilization and Navigation Project Mitigation Project, specifically. This relative cost comparison provides context for both the scale of costs and the likelihood of USACE receiving funds adequate to sustain the SAMP as described.

Response: Program implementation costs were based partly on historical cost data and from discussions with USACE technical staff regularly involved in these types of projects using a conservative approach. The assumptions and data used to generate the management plan-EIS alternatives costs were reviewed and revised where appropriate based upon historical cost information and new information made available since release of the Draft EIS.

Representative Quotes (Correspondence ID): 184
Comments (Comment ID): 643967

Concern Statement: The Draft MRRMP-EIS does not include the actual budgetary impact of implementing any of the alternatives. Resources for habitat protection, land acquisition, wastewater projects, drinking water projects, stormwater projects, just to name some examples, are diverted by the expenditures for the alternatives presented in the MRRMP-EIS.

Response: The costs from the management actions to human considerations (i.e., dredging, navigation, flood risk and interior drainage, recreation, thermal power, hydropower, irrigation, water supply, etc.) have been evaluated to the extent possible and are incorporated in the human consideration technical reports and the Draft EIS. Additionally, the Regional Economic Development evaluation focused on the impacts from the costs of management action implementation, many of which provide economic benefits.

Representative Quotes (Correspondence ID): 222
Comments (Comment ID): 644825

Concern Statement: Annual program implementation costs of Alternative 1 does not approximate historical costs as expected. The costs of Alternative 1 are over double that of the MRRP average annual cost from FY 2004 through 2016 and the average annual cost is higher than any maximum annual expenditure for the MRRP program over the 13-year period of record. These costs are questionable. A major purpose of the No

Action alternative is as a comparison or reference against which to evaluate all other alternatives. Given that the No Action alternative appears to misrepresent what actions were taken in the past and grossly overestimates the costs the MRRMP-EIS is left with an inability to accurately evaluate proposed alternatives including the preferred alternative. The Draft MRRMP-EIS should include annual expenditures for the duration of MRRP by analogous categories shown in EIS Alternatives - Cost Estimates as an addendum to Appendix F and used in the text when comparing costs of various alternatives to the No Action alternative.

Response: Program implementation costs were based partly on historical cost data and from discussions with USACE technical staff regularly involved in these types of projects using a conservative approach. The assumptions and data used to generate the management plan-EIS alternatives costs were reviewed and revised where appropriate based upon historical cost information and new information made available since release of the Draft EIS. The higher cost of Alternative 1 compared to past program expenditures is largely due to the assumption that much of the Shallow Water Habitat creation under Alternative 1 would be accomplished via mechanical top-width widening. This assumption was based partially on the success of the Deer Island top-width widening project and partially because space is more limited for chute and backwater construction when attempting to create 20–30 acres of SWH per river mile. Absent the effects analysis and IRC concept it was forecasted that the program would have followed the Deer Island mechanical construction method as a preferred method for constructing Shallow Water Habitat. The cost estimates have been adjusted since the Draft EIS for Alternatives 3–6. Since the Draft EIS was released it was learned that the majority of initial IRC construction can be accomplished through structure modifications which lowers the estimated cost for these alternatives. The cost estimates in the EIS are for the purpose of comparing the relative estimated costs of the alternatives across the standard 50-year planning horizon used in USACE planning studies. More-detailed annual budgets are developed by the MRRP in collaboration with MRRIC as described in Chapter 2 of the SAMP. Annual costs for the various MRRP actions, and the annual cost for the overall Program will likely vary over time based on changing system conditions. For example, the amount of ESH construction needed in a given timeframe will vary based on the amount of ESH on the system and status of bird metrics, and the amount of operation and maintenance funding will vary based on the condition and performance of habitat structures over time.

Representative Quotes (Correspondence ID): 245
Comments (Comment ID): 644908

Concern Statement: The proposed cost of channel widening is high compared to historical costs and are 16 times higher than the observed cost per acre for the bulk of shallow water habitat creation.

Response: Cost for channel widening were based on past channel widening project cost data for shallow water habitat, two recent IRC sites, and discussions with USACE technical staff regularly involved in these types of projects. The assumptions and data used to generate the management plan-EIS alternatives costs were reviewed and revised using historical cost information. In order to achieve the 20–30 acres of SWH per mile goal under Alternatives 1 and 2 it was determined that top-width widening would need to be the primary method of SWH construction into the future because there are not enough areas projected to be available to achieve those acreages if chute or backwater construction were used as the primary method. Channel widening was also assumed for

impact analysis under Alternatives 3–6 because it is still uncertain what method exactly would be used to create IRCs in every instance under Alternatives 3–6. The NEPA analysis assumed channel widening to display the impacts that **could** result under an all top-width widening scenario. Since release of the Draft EIS it has been determined that much of the initially required IRC habitat can be created through river structure modifications which is a less costly means of achieving IRC habitat than top-width widening. However, it is anticipated that at least some IRC habitat will need to be achieved through top-width widening in the future because eventually all the areas with a high likelihood of success via structure modifications will be used. The projected costs for Alternatives 3–6 have been updated for the Final EIS. Updated assumptions and costs are included in Appendix F of the Final EIS.

Representative Quotes (Correspondence ID): 245
Comments (Comment ID): 644912

Concern Statement: The average total cost for channel widening IRC construction for Alternatives 3–6 is 10 times higher than observed cost per site per year.

Response: Cost for channel widening were based on past channel widening project cost data for shallow water habitat, two recent IRC sites, and discussions with USACE technical staff regularly involved in these types of projects. The assumptions and data used to generate the management plan-EIS alternatives costs were reviewed and revised using historical cost information. In order to achieve the 20–30 acres of SWH per mile goal under Alternatives 1 and 2 it was determined that top-width widening would need to be the primary method of SWH construction into the future because there are not enough areas projected to be available to achieve those acreages if chute or backwater construction were used as the primary method. Channel widening was also assumed for impact analysis under Alternatives 3–6 because it is still uncertain what method exactly would be used to create IRCs in every instance under Alternatives 3–6. However, it is anticipated that at least some IRC habitat will need to be achieved through top-width widening in the future because eventually all the areas with a high likelihood of success via structure modifications will be used. The projected costs for Alternatives 3–6 have been updated for the Final EIS. Updated assumptions and costs are included in Appendix F of the Final EIS.

Representative Quotes (Correspondence ID): 245
Comments (Comment ID): 644913

Concern Statement: The Draft MRRMP-EIS falsely presents channel widening and the comparatively high costs associated with it as a primary management action to create SWH under Alternatives 1 and 2. The historical evidence indicates that other management actions were used to create the majority of shallow water habitat sites and at a much lower cost than is presented in the Draft MRRMP-EIS and specifically the Cost Estimates Table in Appendix F.

Response: Cost for channel widening were based on past channel widening project cost data for shallow water habitat, two recent IRC sites, and discussions with USACE technical staff regularly involved in these types of projects using a conservative approach. The assumptions and data used to generate the management plan-EIS alternatives costs

were reviewed and revised using historical cost information. In order to achieve the 20–30 acres of SWH per mile goal under Alternatives 1 and 2 it was determined that top-width widening would need to be the primary method of SWH construction into the future because there are not enough areas projected to be available to achieve those acreages if chute or backwater construction were used as the primary method. Channel widening was also assumed for impact analysis under Alternatives 3–6 because it is still uncertain what method exactly would be used to create IRCs in every instance under Alternatives 3–6. The NEPA analysis assumed channel widening to display the impacts that could result under an all top-width widening scenario. However, it is anticipated that at least some IRC habitat will need to be achieved through top-width widening in the future because eventually all the areas with a high likelihood of success via structure modifications will be used. The projected costs for Alternatives 3–6 have been updated for the Final EIS. Updated assumptions and costs are included in Appendix F of the Final EIS.

Representative Quotes (Correspondence ID): 245
Comments (Comment ID): 644914

Concern Statement: The proposed No Action and BiOp alternatives presented in the Draft MRRMP-EIS misrepresents what management actions were taken in the past to create shallow water habitat by largely equating shallow water habitat creation to channel widening and grossly overestimating construction costs. Inflating the costs for the No Action and BiOp alternatives relative to historical expenditures prevents the public and resource management agencies from accurately evaluating proposed alternatives including the preferred alternative against the No Action alternative (Alternative 1) and BiOp alternative (Alternative 2). The Draft MRRMP-EIS should clarify why channel widening appears as the proposed primary management action to create shallow water habitat under Alternatives 1 and 2 and also IRCs under Alternatives 2–6 when it would seldom be employed by the MRRP to create existing shallow water habitats and when the SAMP (e.g., Section 4.2.6.3.5) states that while IRCs and shallow water habitat share some attributes, they are different relative to food production and foraging habitat. The MRRMP-EIS should provide explicit evidence for the anticipated benefit to cost of channel widening to achieve IRCs and review the 'best available science' that shows IRCs are superior to shallow water habitat (not hypothesized benefits), or other channel reconfigurations when shallow water habitat has not been shown to benefit recruitment of age-0 pallid sturgeon. The MRRMP-EIS should also revise proposed management actions and associated costs for shallow water habitat construction for the No Action and BiOp alternatives to reflect historical actions employed and actual costs used to create shallow water habitat, or justify why the proposed No Action and BiOp alternatives shallow water habitat proposed costs to continue the existing program have escalated so much. Revise proposed costs for IRC construction via channel widening for Alternatives 3–6 to be in line with observed costs to create the 3 identified IRCs or justify why proposed costs for any additional IRCs have escalated so much.

Response: Cost for channel widening were based on past channel widening project cost data for shallow water habitat, two recent IRC sites, and discussions with USACE technical staff regularly involved in these types of projects using a conservative approach. The assumptions and data used to generate the management plan-EIS alternatives costs were reviewed and revised using historical cost information. In order to achieve the 20–30 acres of SWH per mile goal under Alternatives 1 and 2 it was determined that top-

width widening would need to be the primary method of SWH construction into the future because there are not enough areas projected to be available to achieve those acreages if chute or backwater construction were used as the primary method. Channel widening was also assumed for impact analysis under Alternatives 3–6 because it is still uncertain what method exactly would be used to create IRCs in every instance under Alternatives 3–6. The NEPA analysis assumed channel widening to display the impacts that could result under an all top-width widening scenario. Since release of the Draft EIS it has been determined that much of the initially required IRC habitat can be created through river structure modifications which is a less costly means of achieving IRC habitat than top-width widening. However, it is anticipated that at least some IRC habitat will need to be achieved through top-width widening in the future because eventually all the areas with a high likelihood of success via structure modifications will be used. The projected costs for Alternatives 3–6 have been updated for the Final EIS. Updated assumptions and costs are included in Appendix F of the Final EIS.

Comments (Comment ID): 644915

Concern Statement: Although a mix of land valuation has been used in the Draft MRRMP-EIS, most of the land along the river that would be acquired is not top-quality farmland and the \$4000–\$6000 range is too high.

Response: For evaluating costs at the programmatic EIS level the cost of land was based on a weighted average of agricultural land and recreational land resulting in an average cost based on historical data, including lands of various capacities and quality. Updated assumptions and costs are included in Appendix F of the Final EIS.

Representative Quotes (Correspondence ID): 179
Comments (Comment ID): 645212

Concern Statement: The MRRMP-EIS should reevaluate the amount of mechanically created habitat included and factored in the economic benefits derived from improved ecosystem services including flood risk reduction, improvements to water quality, increased recreation, and benefits to native fish and wildlife.

Response: The Final EIS was updated to summarize the results from many of the other sections to describe the ecosystem services benefits under the alternatives in the Ecosystem Services Environmental Consequences section. For example, the channel widening and IRC habitat provides benefits to flood risk management, especially in the lower reaches of the river. The following ecosystem services benefits were described in the Final EIS in the Ecosystem Services Environmental Consequences section: flood risk management, water quality and water supply, recreation, climate regulation and carbon sequestration, natural resource goods, non-use values, and other cultural services (e.g., quality of life, educational, cultural and spiritual, aesthetic enjoyment, and others). An evaluation of the potential impacts to the most-affected ecosystem services resulting from the alternatives was included in the Final EIS in the Ecosystem Services section.

EC2700 *Environmental Consequences: General Methodology for Establishing Impacts/Effects*

Concern Statement: Allowing the Missouri River to raise up to nine feet for thirty days is not replicating historical flood activity.

Response: Construction of the reservoirs has substantially reduced peak flood magnitudes in the river, shifted seasonality of high and low discharge events, and overall reduced the variability of flows within the year (e.g., Alexander et al. 2012). Nevertheless, substantial variability in river flows remains in the river due to variability in rainfall and snowmelt within the watershed (with flow regulations by USACE). The spawning cue alternatives were designed based on historic records prior to the construction of the reservoir system. The ESH flow alternatives have prolonged periods of sustained higher flow and

are designed to create sandbar habitat, not to replicate historic floods. The human considerations analysis was performed to evaluate the impacts of the ESH releases that would occur for Alternatives 4 and 5.

Representative Quotes (Correspondence ID): 17
Comments (Comment ID): 626407

Concern Statement: There were questions regarding how many large spring flows occurred on the river in three-year intervals over the 82-year period of record.

Response: Spawning cue flows under Alternative 6 have been designed to recreate some the variability in natural flows that has been substantially curtailed by the construction of the reservoirs along the upper Missouri River.

The spawning cue flows under Alternative 6 would build on the spring flows already occurring naturally. As summarized in Table 3-4 in the Draft EIS, the 82-year hydrological record would have resulted in 11 full completed spawning cue flow events in both March and May, and an additional 6 events in March only.

There would be negligible effects on water elevations of the lower three reservoirs (Lake Sharpe, Lake Francis Case, Lewis and Clark Lake) under Alternative 6. In the upper three reservoirs, water elevations would generally only be up to a few feet lower than under Alternative 1, particularly in Fort Peck Lake and Lake Sakakawea. Water elevations in Lake Oahe would vary more. However, over the 82-year hydrological record, water elevations in Lake Oahe under Alternative 6 (compared to Alternative 1) are lower by more than 5 feet in only three years (late spring and summer of 1981, late spring and early summer of 2000, summer and fall of 2003). Further, it is noted that the natural variability in precipitation results in substantially larger variability in water elevations in all three upper reservoirs.

Comments (Comment ID): 645524

Concern Statement: The Draft EIS does not explain how the impact matrices are used, and there are no summaries of monetary or non-monetary values that would allow the alternatives to be compared in the aggregate.

Response: Table 2-32 summarizes the consequences of implementing each of the alternatives. No attempt was made by USACE to provide combined monetary or non-monetary summary values that would allow the alternatives to be compared in the aggregate because there is no common metric or relative weighting schemes available to combine the diversity of resources evaluated in the MRRMP-EIS.

Representative Quotes (Correspondence ID): 223
Comments (Comment ID): 646378

Concern Statement: The Draft EIS does not account for the reduction of material movement throughout the river system.

Response: The necessity of conducting a sediment budget was considered during initial study scoping but determined to be unwarranted for evaluation of study alternatives. This decision was based on the fact that alternatives will not alter the trapping of sediments

within the reservoir system. None of the alternatives include sediment management or measures to pass sediments through the reservoir system to the navigation channel downstream of Gavins Point Dam. In addition, based on the 82-year flow record, the flows in the lower Missouri River and sedimentation processes would continue to be dominated by natural reservoir release events (2011, 1997) and significant tributary inflow events (1993). Analysis was performed with a “Year 15” designation that included modeling of conditions 15 years in the future. While not intended to represent detailed estimates of future reservoir and channel conditions, the results do provide an alternative comparison methodology. Comparison of results determined only minor changes between alternatives.

Representative Quotes (Correspondence ID): 34

Comments (Comment ID): 645751

Concern Statement: The economic conclusions and modeling on Alternative 3 are inaccurate and incomplete due to the failure to provide robust and accurate modeling and impact data on interior drainage, and also because the Draft MRRMP-EIS stipulates that economic analysis of the floodplain could not be completed. Translation of the impacts to the four sample sites to the rest of the floodplain was not attempted and extrapolation from the four sites to other levee areas was not feasible since the hydraulics, hydrology and drainage varies between sites. Additionally, the modeling limits itself to the loss of production on lands predicted to be acquired and does not include transportation, infrastructure, energy, water supply and the effects of economic multipliers from those impacts. These omissions and the limitations of modeling should be clearly described in the MRRMP-EIS.

Response: USACE believes the analysis conducted for interior drainage is adequate for determining the relative impacts of the alternatives. The assumptions and limitations of the analysis are clearly presented in the Final EIS.

Comments (Comment ID): 645555, 645488, 641125, 637267, 636859, 633864, 633840, 633833, 633810

Concern Statement: Support of the preferred alternative does not include the one-time flow test. The Draft MRRMP-EIS did not model or assess the impacts associated with this action. USACE cannot implement an action when the impacts have not been adequately assessed. A full NEPA review process must be completed before this action is initiated.

Response: The following text was inserted within the EIS, Section 3.12.2.1:

The Missouri River system as currently operated provides substantial flood damage reduction and benefits to the entire basin. Study alternatives include modifying operations of the Missouri River reservoir system with both higher and lower reservoir releases during select periods for species habitat benefits. The current HEC-ResSim and HEC-RAS analysis shows the potential for negative impacts to flood damage reduction for alternatives that include changes in reservoir flow releases. The current study methodology, which employs an 82-year period of record, is suitable for alternative comparison and providing an indication of change in flood risk. However, the methodology does not simulate a sufficient number of events and possible runoff combinations within the large Missouri River basin to evaluate potential change in downstream flood risk. Prior to implementing any management action that alters reservoir operations, a comprehensive flood risk evaluation will be conducted per

USACE requirements. The level of additional hydrologic analysis will be based on USACE guidance and requirements and will identify the change in reservoir pool probability, reservoir release frequency, river stage-frequency, and river stage-duration.

Comments (Comment ID): 645243, 644749, 641050, 640731, 635152, 628575

Concern Statement: The table labeled Environmental Consequences of the Actions Compared to No Action in the Executive Summary of the Draft EIS is confusing, and needs to be printed in color for it to be interpreted.

Response: In the Final EIS, Table 2-32 presents the Environmental Consequences summary. This table is in black and white and provides a detailed summary of environmental consequences with additional explanatory text. The summary table in the Draft EIS was consistent with the text in Chapter 3 of the EIS, but did contain summary information which was intended as a convenience for the reader. It was not meant to be used in place of the full analysis in the body of Chapters 2 and 3 of the EIS as explained in the introductory text for the table contained in the Draft EIS:

“The following table provides a summary comparison of the general environmental consequences of each action alternative compared to Alternative 1—the No Action alternative—in terms of being beneficial or adverse. The impacts of the No Action Alternative and the Action Alternatives are provided in-detail under each resource topic in Chapter 3-Affected Environment and Environmental Consequences.”

Representative Quotes (Correspondence ID): 179, 225
Comments (Comment ID): 645229, 644422, 645215

Concern Statement: Alternative 2 was based on outdated data and not completely aligned with the latest scientific priorities. The Draft MRRMP-EIS does not explain the use of this outdated data for development of Alternative 2.

Response: The assumptions for Alternative 2 were provided by USFWS and documented via planning aid letter (USFWS 2015). For transparency, this planning aid letter was also shared with MRRIC at the same time it was shared with USACE. USACE believes the most scientifically advanced and proactive plan for adaptive management is the plan developed using the results of the recent effects analysis. The 2003 BiOp was developed before the recent effects analysis. To assume Alternatives 1 or 2 would follow the effects analysis results and new SAMP would not result in a useful comparison because it would result in comparing the newly proposed alternatives to 2003 BiOp alternatives that would assume the very existence of the alternative plans being proposed.

Representative Quotes (Correspondence ID): 240
Comments (Comment ID): 644959

Concern Statement: The Draft MRRMP-EIS provides "fundamental" and "sub objectives" for each species, but summarizing them as part of the purpose and need statement itself would properly narrow project goals and the means of accomplishing those goals. As a result, ESA goals would be clarified and prioritized over human consideration impacts.

Response: USACE used the purpose, need, and objectives to design a reasonable range of alternatives. The purpose of meeting ESA responsibilities does not free USACE from other responsibilities or from considering the impacts of ESA related actions in the decision-making process. USACE has identified a preferred alternative that attempts to

identify and correct limiting factors in the ecosystem that could cause jeopardy. USACE identified the alternative that met the species objectives and had the least detrimental impacts across a range of interests.

Representative Quotes (Correspondence ID): 223
Comments (Comment ID): 644940

Concern Statement: Time-series analysis is appropriate for a programmatic Draft MRRMP-EIS that anticipates future effects over 5, 15, and 50 years. However, the Draft MRRMP-EIS uses a fixed reference point in time represented by the Missouri River baseline assessment.

Response: To facilitate plan development, an implementation timeframe of 15 years was chosen for this planning process and EIS. This is a reasonable timeframe for identification of actions which, based on the current state of the science, may provide meaningful biological responses while recognizing the potential, based on AM, that substantive changes to the suite of actions identified in this MRRMP-EIS may be necessary in 15 years. However, effects to resources were based on an 82-year hydrologic period of record (POR) in order to provide an indication of the potential range of effects under the variable hydrologic conditions occurring in the Missouri River basin. The geographic scope of the federal action includes the Missouri River within its meander belt from Fort Peck Dam in Montana to its confluence with the Mississippi River near St. Louis, Missouri, and the Yellowstone River from Intake Dam at Intake, Montana, to its confluence with the Missouri River.

Representative Quotes (Correspondence ID): 166
Comments (Comment ID): 644882

Concern Statement: If the newer technologies and datasets could be incorporated into existing operational analysis, then many of the highly negative, human considerations costs (2011 flood, 2012 drought, projected as exemplary of future events) could be avoided. Additionally, operational decisions by rules aimed at reducing endangered species "take" for the birds above and below the reservoirs could be improved.

Response: USACE uses the Master Manual and annual operating plans to make decisions regarding the operations of the Missouri River system and balance a wide spectrum of interests. The modeling conducted for this plan used the most up to date information available and complies with USACE economic guidance and methods.

Representative Quotes (Correspondence ID): 166
Comments (Comment ID): 644880

Concern Statement: Economic modeling in the Draft MRRMP-EIS relies on old, outdated, and inaccurate information to assess impacts.

Response: The economic modeling complies with USACE economic guidance and methods. The human consideration models used in the EIS have been USACE certified and/or approved for use. The navigation NED evaluation has been updated to 2018 values. The evaluation includes an assessment of how river flows would affect commercial sand and gravel production, based on transportation data for the Missouri River as well as interviews with the transportation industry and transportation experts. The navigation RED evaluation used a USACE-certified RECONS model with 2004 cost data, adjusted to 2018 dollars, to estimate the impacts to the barge, towing, and port services sectors; and commercial sand production and associated truck transportation sectors.

Representative Quotes (Correspondence ID): 176
Comments (Comment ID): 644754

Concern Statement: It is not clear if Alternative 5 includes the spring pallid sturgeon spawning release and the impacts could be misrepresented based on the actual modeling provisions.

Response: Alternative 5 does not include the spring pallid spawning release. This information has been clarified in the Final EIS.

Representative Quotes (Correspondence ID): 107
Comments (Comment ID): 643895

Concern Statement: Alternative 3 has the least impacts on the authorized purposes.

Response: Comment noted.

Representative Quotes (Correspondence ID): 216
Comments (Comment ID): 643456

Concern Statement: The conclusion in the Draft MRRMP-EIS that the alternatives would not represent an irreversible or irretrievable commitment of resources assumes that there will be sufficient runoff into the Missouri River reservoirs every spring to replenish the volume of water that is released the previous year. It is incorrect to assume that water will be restored the following year.

Response: The release of water from one year to the next is not considered by USACE to be an irreversible or irretrievable commitment of resources. An irreversible or irretrievable commitment of resources refers to impacts on or losses to resources that cannot be recovered or reversed. Information was added to the EIS to clarify that water resources would generally be restored based on an assumption of annual precipitation but in some instances (i.e., period of drought) restoration may take several years.

Representative Quotes (Correspondence ID): 239
Comments (Comment ID): 642805

Concern Statement: It is unclear from the Draft MRRMP-EIS whether (and at what level) the various models have been subjected to scientific review, verification, and refinement. The models have not been made available for review, nor were state experts who have local knowledge and experience consulted regarding the models.

Response: The Human Consideration models presented to the ISETR for review included those areas that were not previously USACE-approved models. These included Water Supply, Thermal Power, Irrigation, Cultural Resources, and Navigation. These models underwent USACE model approval process and have all been approved by USACE Headquarters for use on the Management Plan. The models for the other HC resource areas, including hydropower, flood risk management, interior drainage, and recreation, had been previously USACE approved for use and therefore, did not need additional review approval. References to these models have also been shared with the ISETR. USACE has coordinated with several industry and local experts for data and input related to human considerations.

Representative Quotes (Correspondence ID): 96
Comments (Comment ID): 640185

Concern Statement: It is wholly proper to consider human impacts and seek to minimize them, but priority must at some points be given to species recovery.

Response: USACE has identified a preferred alternative that meets species objectives while minimizing impacts to other river interests.

Representative Quotes (Correspondence ID): 131

Comments (Comment ID): 640167

Concern Statement: While the Draft MRRMP-EIS provide a reasonable range of actions to recover the three species the Draft MRRMP-EIS fails to provide information that allows the public to make an assessment of the likelihood of recovery or other relevant factors.

Response: Section 2.9 of the Final EIS provides a clear comparison of alternatives in terms of the species objectives, Affected Environment and Environmental Consequences and provides a description of how those factors were weighed in the decision. Sections 3.3 and 3.4 of the EIS provide a more-detailed comparison of the alternatives in terms of species objectives.

Representative Quotes (Correspondence ID): 131

Comments (Comment ID): 640133

Concern Statement: The Draft MRRMP-EIS purports to be a long-term, holistic solution to problems on the Missouri River, but it fails to address bed degradation, which is one of the most critical problems facing USACE. Rather than passively observing the problems with riverbed degradation, USACE should take immediate, active steps to solve the problem.

Response: The Missouri River Bed Degradation Feasibility Study answers the fundamentally different question of what measures could be cost-effectively employed to minimize bed degradation damages from St. Joseph, MO to Waverly, MO. It does not test the Missouri River Recovery Management Plan-EIS alternatives. While aggradation and degradation processes are known to be occurring within the basin, those processes will continue regardless of the implementation of any alternative. These processes are discussed within multiple sections of the Draft EIS. Based on modeling results the assumption is that future bed change affects all project alternatives to a sufficiently similar level.

Additional flow releases to compensate for bed degradation is not mandated in the Master Manual and has not been included in the alternatives modeling or results.

Representative Quotes (Correspondence ID): 122

Comments (Comment ID): 638311

Concern Statement: A brief accounting of the quantification of screening of alternatives based on effects on human considerations should be presented in the Executive Summary of the MRRMP-EIS.

Response: This information is provided in Chapters 2 and 3 of the Draft and Final EIS and is too detailed for an Executive Summary.

Representative Quotes (Correspondence ID): 179

AE0100 *Affected Environment: River Infrastructure and Hydrologic Processes*

Concern Statement: Notching of the dikes is eating away the ground and will impact adjacent agricultural property.

Response: The effect of notching on the adjacent land was addressed for example in Section 3.2 of the Draft EIS. “Modifying structures by creating notches or lowering the structure encourages erosion of the riverbank and causes the top width of the river to increase.” In addition, USACE notching actions performed to cause bank erosion are only constructed in areas where USACE has a real estate interest in the adjacent land.

Representative Quotes (Correspondence ID): 51
Comments (Comment ID): 628670

Concern Statement: The description of geomorphology of the Garrison Reach discussed in the "Degradation and Bank Erosion" and "Reservoir Sediment Deposition and Aggradation" sections is not inaccurate but is written as if the degradation and aggradation occurring in the Garrison Reach are two separate and independent processes.

Response: We agree that degradation and aggradation are closely linked, that there are various transitional zones and conditions, and that boundaries between these processes constantly shift with time due to varying flow conditions in the river. The connection between degradation and aggradation is reflected by the text of the first paragraph of Draft EIS Section 3.2.1.3; the reference of Skalak et al. (2013) has been added to this paragraph.

The more detailed descriptions in Section 3.2.1.4 of first degradation and then aggradation set the stage for the discussion of environmental consequences, which are different for each of these processes. Transitional conditions would be addressed locally through site-specific considerations during project implementation, as applicable.

Representative Quotes (Correspondence ID): 239
Comments (Comment ID): 645389

Concern Statement: The Ice Dynamics section lacks detail on the effect of ice on river flows and stages in North Dakota. Ice jam-induced flooding is a concern on the Missouri River and in the Bismarck-Mandan area.

Response: The following paragraph has been added to the EIS after the first paragraph in subsection “Ice Dynamics” within Section 3.2.1.4: “Although ice-induced flooding can occur anywhere along the Missouri River, ice dynamics is of heightened concern for the Bismarck-Mandan area in North Dakota. At the beginning of winter when ice cover is forming, river stage usually rises between several feet in a short period of time. During the ice-out period, there is a high risk of ice jams and river stages can fluctuate drastically with little to no warning. Typically, USACE will temporarily reduce releases from Garrison Dam to prevent ice-induced flooding during freeze-in and ice-out periods as conditions permit.”

Representative Quotes (Correspondence ID): 239
Comments (Comment ID): 645390

Concern Statement: Interception and rearing complexes (IRCs) should be adequately monitored for impacts to the channel.

Response: Implementation of IRCs would include monitoring and evaluation, as stated in the EIS and in Chapter 5 of the SAMP. In addition, the proposed project is designed to apply adaptive management to adjust the initial suite of actions over time.

Representative Quotes (Correspondence ID): 222
Comments (Comment ID): 644832

Concern Statement: Due to geomorphology and sediment carrying capacity of flows in the Garrison Reach of the Missouri River the ability of the Garrison Reach, and the river in general to continuously create sandbar habitat with flows over the long-term is questionable.

Response: The potential for sandbar creation from flow releases would vary along the Missouri River, based on many factors including site-specific flow velocities, sediment size, sediment supply, and channel configuration. For the Garrison to Oahe Reach, the potential for sandbar creation would be highest in the lower part of the reach, downstream of Bismarck, ND. Section 2.7.2 of the EIS provides information on sandbar habitat and flow volume. Available information and analysis performed by USACE indicate that there is not a sand volume limitation for the formation of sandbars in the Garrison Reach over the 50-year planning horizon for this project.

Representative Quotes (Correspondence ID): 96
Comments (Comment ID): 640276

EC0100 *Environmental Consequences: River Infrastructure and Hydrologic Processes*

Concern Statement: Extended flooding and an increase in flooding frequency would compromise the integrity of levees forcing burdens and risks on the people living within the adjacent area. Coordination of operations and flood fighting activity become increasingly critical and costly as river stages increase. Management of the river for flood control and drainage should be prioritized.

Response: The Draft EIS extensively addresses Missouri River reservoir operation and the impacts of the different alternatives. USACE recognizes that flooding, erosion, and stress on the riverine infrastructure are affected by reservoir releases which influence river flow rate, water levels, and flow velocities at any given time. The various alternatives may alter these parameters on shorter time scales. However, extreme or large-scale events are not usually affected by the various alternatives. For example, the flows of the flood of 2011, for example, greatly exceeded the maximum flow release of 60,000 cfs under any of the Alternatives. Specifically, at Gavins Point, the flow of the 2011 flood was approximately 160,000 cfs, lasting two months; this period was followed by flows of 50,000 to 60,000 cfs for another four months.

Flow releases under the Alternatives would be scheduled to avoid or minimize potential flooding along the river as is stated in multiple locations, refer to each alternative specifically for details (e.g., spawning cue release text, Section 2.8.8.2) “The magnitude of both the March and May Gavins Point spring pulses would be constrained by the Gavins Point spring pulse downstream flow limits.” Further information is provided in the Draft EIS in Section 3.2.2.3, Impacts on Hydrology from the Alternatives, and Section 3.12, Flood Risk Management and Interior Drainage.

The recommended plan does not include a change in reservoir releases. With respect to flow alteration alternatives, USACE recognizes that additional evaluation would be

necessary prior to implementation. Within Section 3.12.2.1, Impacts Assessment Methodology, a new paragraph was inserted:

The Missouri River system as currently operated provides substantial flood damage reduction and benefits to the entire basin. Study alternatives include modifying operations of the Missouri River reservoir system with both higher and lower reservoir releases during select periods for species habitat benefits. The current HEC-ResSim and HEC-RAS analysis shows the potential for negative impacts to flood damage reduction for alternatives that include changes in reservoir flow releases. The current study methodology, which employs an 82-year period of record, is suitable for alternative comparison and providing an indication of change in flood risk. However, the methodology does not simulate a sufficient number of events and possible runoff combinations within the large Missouri River basin to evaluate potential change in downstream flood risk. Prior to implementing any management action that alters reservoir operations, a comprehensive flood risk evaluation will be conducted per USACE requirements. The level of additional hydrologic analysis will be based on USACE guidance and requirements and will identify the change in reservoir pool probability, reservoir release frequency, river stage-frequency, and river stage-duration.

Representative Quotes (Correspondence ID): 17, 19, 156

Comments (Comment ID): 626459, 626497, 644461, 644479, 644480, 644481, 644483, 645904

Concern Statement: The Draft EIS fails to accurately analyze the amount of sediment in the system. The Draft EIS also fails to analyze how the alternatives would impact sediment loading. The use of a 20-year period to extrapolate for the 82-year period of analysis to analyze for sediment is insufficient. A robust sediment model needs to be created to adequately analyze the impacts of sediment loading and their effect on the sand and gravel industry in the Final EIS. Sediment load in the river is decreased and the effects of past actions on the ability of the river to create sandbars over time is unknown.

Response: Channelizing the river and construction of dams has indeed drastically reduced the volume of sediment in the river. The proposed project is based on the current sediment transport load with current condition for water development (all reservoirs, navigation channel, and flow control structures in place).

Reservoir releases under Alternatives 4 and 5 intend to use flow to create sandbar habitat. Releases would mobilize sediment and result in the formation of sandbars. The flow – sandbar relationship is based on data and observations from previous events that created sandbar habitat such as 1997 and 2011. Within the 82-year period of record, multiple reservoir releases occur during period of storage evacuation that would create sandbar habitat. For these alternatives, additional releases would be included to achieve the intended sandbar habitat creation goals. (i.e., creation of sandbars). The Draft EIS (Section 2.7.2) provides information on sandbar habitat and flow volume.

The necessity of conducting a sediment budget was considered during initial study scoping but determined to be unwarranted for the evaluation of study alternatives. This decision was based on the fact that alternatives will not alter the trapping of sediments within the reservoir system. None of the alternatives include sediment management or measures to pass sediments through the reservoir system to the navigation channel downstream of Gavins Point Dam. In addition, based on the 82-year flow record, the flows in the lower Missouri River and sedimentation processes would continue to be dominated by natural reservoir release events (2011, 1997) and significant tributary

inflow events (1993). Analysis was performed with a “Year 15” designation that included modeling of conditions 15 years in the future. While not intended to represent detailed estimates of future reservoir and channel conditions, the results do provide an alternative comparison methodology. Comparison of results determined only minor changes between alternatives. Comparison of alternatives does not indicate a significant difference in downstream sediment loading between alternatives.

Representative Quotes (Correspondence ID): 96, 197
Comments (Comment ID): 640274, 645280

Concern Statement: The selected alternative should not increase Missouri River bed degradation or lateral bank erosion. Higher releases could further increase degradation of the river bank, bottom, and channel in already compromised locations due to higher velocities. The Draft MRRMP-EIS states that degradation of 0.5 feet under Alternatives 4 and 5 is considered small. This is not small, as over the long-term, degradation would accumulate and shift the water surface profile. ESH-creating releases would continuously move sediment from upstream to downstream perpetuating the significant changes in geomorphology that currently exists in the Garrison Reach. A determination of impacts to geomorphology under all of the alternatives as being not significant is inaccurate. The sole purpose of the ESH-creating releases is to cause significant change in the geomorphology of the river. Mechanical creation of ESH may not have a system-wide effect on geomorphology but on a smaller scale can have morphological effects.

Response: The dominant factors for degradation in the river downstream of dams is the combination of sediment trapped by the large reservoirs of the system, and erosion during natural high flow events. Flow releases under Alternatives 4 and 5 could also have an effect. Existing data suggest that degradation response to releases under Alternatives 4 and 5 could “perhaps be on the order of up to 0.5 foot” (EIS Section 3.2.2.4). However, the available data are limited. While it is reasonable to assume that additional degradation would occur, additional study would be needed to better define a change in the degradation rate under Alternatives 4 or 5 (should one of these alternatives be considered as the preferred alternative at a later time).

Regarding geomorphology, effects from the Alternatives would overall be small compared to existing conditions, but could be large locally. This is already described in the conclusion section.

Representative Quotes (Correspondence ID): 192, 205, 216, 233, 239
Comments (Comment ID): 641636, 642819, 646283, 645758, 645396, 645395

Concern Statement: Decreased river levels will also impact groundwater wells along the River with decreased capacities, decreased water quality, and increased chemical and pumping costs.

Response: Groundwater is discussed within multiple sections of the Draft EIS. The initial resource discussion occurs within the Draft EIS, Section 3.2.1.5 Groundwater. Impacts on groundwater were assessed qualitatively because they are largely a function of stage in the river. In general, prolonged periods of higher stages would result in higher groundwater elevations; lower stages would result in lower groundwater elevations.

As stated in the Draft EIS Section 3.2.2.2, Summary of Environmental Consequences, “Over the long term and considering the hydrologic variability in the POR, the action alternatives would be expected to have small to negligible, adverse impacts on the

hydrology, geomorphology, river infrastructure, and groundwater relative to the No Action alternative. However, impacts could be large temporally and locally.”

Groundwater consequences for each alternative are further discussed in the Draft EIS Table 3-3. Additional discussion on groundwater impacts are further presented within the Draft EIS, Section 3.2.2.6 Impacts on Groundwater from the Alternatives.

Within the conclusions, Draft EIS Section 3.2.2.7, “Changing flows would affect groundwater levels locally under Alternatives 1, 2, 4, 5, and 6. No impacts would occur to groundwater levels from changing flows under Alternative 3 due to the absence of the reoccurring flow management actions.”

Representative Quotes (Correspondence ID): 205, 216

Comments (Comment ID): 643451, 645871

Concern Statement: The MRRMP-EIS should assess the manner in which the system will operate in the future over changing environmental conditions, specifically changes in sedimentation and hydrology, and impacts to the integrity of the flood control pools.

Response: Sedimentation in the reservoir system is ongoing and part of the existing conditions considered for this project. The goal of the EIS is to address the impacts of the proposed project relative to existing conditions. Operation of the System due to changes in the storage capacity under existing conditions, or any of the alternatives, is outside of the scope of the EIS.

Representative Quotes (Correspondence ID): 197

Comments (Comment ID): 645271

Concern Statement: The use of the 2012 channel geometry used in the HEC-RAS model will generally underestimate the water surface profile and it should be noted that the waters surfaces will likely be higher than modeled.

Response: The Missouri River is a dynamic system that is changing constantly over the study area, which extend from Ft. Peck dam downstream to the Missouri River mouth at St. Louis. Some areas have experienced continued degradation since 2012 while other areas have experienced aggradation. Regardless, all alternatives were modeled with HEC-RAS using the same geometry and the comparison between the Alternatives is valid.

Representative Quotes (Correspondence ID): 239

Comments (Comment ID): 645383

Concern Statement: Some of the action alternatives, in particular Alternatives 4 and 5, cause significant changes in reservoir elevations and releases from Garrison Dam. While the effect of the alternatives on reservoir elevations is small compared to natural variations, when a full ESH-creating release is implemented, the volume of water released is not insignificant. Additionally, some of the alternatives cause lower reservoir levels during drought periods that can have an incremental effect that can be devastating.

Response: The ResSim model allows comparison between pool elevations for the various alternatives over the 82-year period of record used in the analysis that is based on current water development conditions (e.g., reservoirs are installed for the entire period). Model results show that the effect of flow releases under Alternatives 1, 2, 4, 5, and 6 on reservoir elevations are typically small compared to the effect caused by the natural variability in runoff from the watershed. The Human Considerations analysis evaluates

the impacts of those ResSim results on resources including boat access, irrigation, and municipal water supply. While some years may have detrimental impacts, other years are positive. The Draft EIS in Chapter 3, Affected Environment and Environmental Consequences, contains a detailed discussion of the analysis that was performed for the many human considerations and how those resources are affected by the various alternatives. This analysis includes the evaluation of different reservoir pool levels and river flow rates.

Representative Quotes (Correspondence ID): 239
Comments (Comment ID): 645384, 645391

Concern Statement: The Draft MRRMP-EIS does not mention sandbar erosion and deposition, which is a critical part of river geomorphology, and is relevant to all of the proposed alternatives.

Response: The words “sandbar erosion and deposition” have been added to the EIS in Section 3.2.1.4. In addition, many of the supporting documents discuss sandbar processes. Finally, additional discussion related to the flow and sandbar relationship will be provided in the Final EIS as stated in the Draft EIS Section 2.7.2, pg. 2-39, with the document referenced (Fischenich et al. in prep).

Representative Quotes (Correspondence ID): 239
Comments (Comment ID): 645388

Concern Statement: Stating that the change in hydrology expected above 35,000 cfs is insignificant is inaccurate. Additionally, implementing the fall release for 175 days throughout the entire winter is infeasible and these high flows are unacceptable due to the increased risk of ice-induced flooding. Increased flows under ice conditions with the resulting increased velocities would increase erosion and negatively affect the longevity of sandbars.

Response: The text in Section 3.2.2.3 has been revised. The ResSim model for the fall release does not release flows for 175 days, the model is constrained by maximum winter releases that start when the navigation flow support season ends on Dec 1 or Dec 10 if the season is extended.

Representative Quotes (Correspondence ID): 239
Comments (Comment ID): 645392

Concern Statement: Understanding the changes in dam safety risk is critical. The MRRMP-EIS needs to quantify the risk of the proposed flows under an alternative related to the increase in use of spillways, affecting long-term reliability. A determination that these impacts are not significant is premature because the risk to dam safety has not been assessed.

Response: As the quoted text in the Draft EIS states, these risks have not been quantified. However, the preferred alternative 3 does not include any increase flow changes to current operations. In addition, the following text was inserted within the EIS, Section 3.12.2.1, Impacts Assessment Methodology:

"The Missouri River system as currently operated provides substantial flood damage reduction and benefits to the entire basin. Study alternatives include modifying operations of the Missouri River reservoir system with both higher and lower reservoir releases during select periods for species habitat benefits. The current HEC-ResSim and HEC-RAS analysis shows the potential for negative impacts to flood damage

reduction for alternatives that include changes in reservoir flow releases. The current study methodology, which employs an 82-year period of record, is suitable for alternative comparison and providing an indication of change in flood risk. However, the methodology does not simulate a sufficient number of events and possible runoff combinations within the large Missouri River basin to evaluate potential change in downstream flood risk. Prior to implementing any management action that alters reservoir operations, a comprehensive flood risk evaluation will be conducted per USACE requirements. The level of additional hydrologic analysis will be based on USACE guidance and requirements and will identify the change in reservoir pool probability, reservoir release frequency, river stage-frequency, and river stage-duration."

Comments (Comment ID): 645397

Concern Statement: Information should be better communicated in the Draft MRRMP-EIS on how constructed IRC habitat can decrease stage for most flows on the lower river and the impacts IRC construction would have on bed and hydrologic conditions.

Response: IRCs may locally decrease the stage slightly due to added conveyance; however, IRC effects on river flow levels is regarded as incidental. IRC habitat project formulation was not intended to provide flood damage reduction.

IRC's would be designed to create effective interception hydraulics, food producing, and foraging habitats on the Lower Missouri River. For these projects to be effective and sustainable, the IRC projects would be designed such that the navigation channel and overall bed and hydrological conditions would largely remain unaffected. Refer to the supporting technical documents for a thorough description of modeling methodology, assumptions, and limitations.

Comments (Comment ID): 645587, 645790

Concern Statement: Construction activities in the inter-dam reaches would disturb the sediment in the river causing it to flow downstream and accumulate in the delta. This action would increase aggradation in the delta, thereby increasing the backwater effect and river stage. It is recommended that mechanical ESH construction in inter-dam reach use sediment from the downstream delta.

Response: ESHs are built using sand from the adjacent area. Restrictive criteria are employed in ESH design to avoid river impacts. Specifically, a small amount of sand is typically added onto an existing bar that is slightly below the water surface from the adjacent river area. ESHs are designed to balance conveyance within the same river section to avoid a net impact on flow area within that section. Aside from being very expensive, transporting sand from an area downstream of the river to an area upstream would alter the stage in the river in both areas and could thus affect flood levels.

Representative Quotes (Correspondence ID): 239

Comments (Comment ID): 645994

Concern Statement: The impacts to downstream flow support resulting from past management actions related to allocation of sedimentation to the Annual Flood Control and the Carryover Pools and viewing the operational guide curves as numerically fixed are neither mentioned nor assessed in the Draft MRRMP-EIS. The numerically-fixed guide

curves and reduction in pool capacity create a condition where the downstream flow support level established by the 2004 Master Manual fails to perform as presented.

Response: The EIS addresses the impacts of the proposed project relative to existing conditions. The impacts on sedimentation as a result of the alternatives would be comparatively small compared to the impacts from the variability in natural flows.

Representative Quotes (Correspondence ID): 197
Comments (Comment ID): 645270

Concern Statement: The Draft MRRMP-EIS fails to address the issue of sediment in the system and the lack of material movement. USACE needs to develop sediment analysis that examines this important component for pallid sturgeon recovery. Changes in flow, without enhancing sediment load are not impactful and waste water in the system. USACE also needs to provide assurances that IRC construction and maintenance will not impact commercial sand dredging.

Response: Available information and analysis performed by USACE indicate that there is not a sand volume limitation for the formation of sandbars in the Gavins Point or Garrison Reach over the 50-year planning horizon for this project. This discussion is provided in Section 3.2 of the Final EIS. There currently is no scientific evidence that a lack of sediment in the lower river is inhibiting recruitment of pallid sturgeon and this was not identified as a priority hypothesis at this time. Sediment transport issues are the subject of the Lewis and Clark sediment management study funded by the MRRP (available at www.moriverrecovery.org). Phase II of this study is ongoing. In the future, it is likely that MRRP will continue to fund sediment management studies where sediment issues intersect with ESA issues. IRC construction and maintenance will include site specific NEPA analysis that will seek to avoid and/or minimize impacts to other river uses.

AE100 ***Affected Environment: Pallid Sturgeon***

Concern Statement: Hypoxic zone within Missouri River reservoirs is a major source of the decline and disappearance of the pallid sturgeon. In a recent study, scientists show that oxygen-depleted dead zones between dams in the upper Missouri River are directly linked with the failure of endangered pallid sturgeon hatched embryos to survive to adulthood.

Response: Management hypotheses that dealt directly with the perceived anoxia issue in the headwaters of Lake Sakakawea were considered by the panel of experts that developed the Effects Analysis, which was the basis for alternatives development in the Draft EIS. A number of hypotheses dealt with the anoxia issue through an increase in drift distance or a reduction in drift time. Alternatives development gave consideration to management actions associated with these hypotheses and was discussed in Sections 2.3 and 2.5.2 of the Draft EIS.

Representative Quotes (Correspondence ID): 128
Comments (Comment ID): 637082

Concern Statement: Habitat is the most critical component impacting pallid sturgeon on the Missouri River and the loss of 100,200 acres of aquatic and 67,800 acres of terrestrial

habitat acres in the channel below Sioux City has had the greatest impact on pallid sturgeon and other native fish species on the channelized Missouri River.

Response: The best available science remains inadequate to quantify the effects of physical (abiotic) changes to the Missouri River on pallid sturgeon population dynamics, in spite of the availability of the new information since the 2003 Amended BiOp was issued. Efforts to push beyond a basic understanding of the species' ecology to facilitate predictions of environmental causes and effects on the fish are still compromised by fundamental information gaps. Lines of evidence for many of the pallid sturgeon management hypotheses are limited to theoretical deduction, inference from sparse empirical datasets, or expert opinion. The independently-led Effects Analysis came to these conclusions. Given the high level of uncertainty regarding the necessary actions to address the listed species' needs, USACE and USFWS agreed that proceeding under a rigorous and progressive SAMP, based on the results of the Effects Analysis, would provide the most effective, efficient, and accountable way to manage risks to the species, address key uncertainties, and identify the scope and scale of actions ultimately required to achieve the MRRP objectives without wasting resources on actions which prove ineffective.

Representative Quotes (Correspondence ID): 237
Comments (Comment ID): 642884

Concern Statement: Much of the current science on pallid sturgeon in the upper Missouri River basin has not been consistently applied within the Draft MRRMP-EIS and the State of Montana's institutional knowledge has not been utilized in the development of meaningful alternatives. To further this concern, the justification for excluding RPMA 1 in the MRRMP-EIS is poorly conveyed and a lack of coordination with the State has perpetuated the issue.

Response: The Effects Analysis was led by a group of independent scientists that used the best available science to develop a foundational understanding of pallid sturgeon life history requirements and assess the effects of system operations and actions on the species' populations and habitats. State, private, and Federal agency biologists were given numerous opportunities to provide input into the Effects Analysis (e.g., review, workshops, etc.) and the MRRMP-EIS (e.g., review, MRRIC, etc.) and that input was considered through the development of both. Coordination with individual agencies runs counter to the independent and open process adopted by USACE and USFWS that was used to develop the Effects Analysis; this process has led to an analysis that is credible, defensible, and independently scrutinized. Exclusion of input does not mean it was not considered; in some instances, better information was available or the input was not supported by the available science. All credible scientific input has been considered through the development of the EA and MRRMP-EIS. Finally, the appropriate avenue for state coordination on components of the MRRMP-EIS (e.g., inclusion of RPMA 1) would be with USFWS through the Fish and Wildlife Coordination Act or their state's MRRIC representative.

Representative Quotes (Correspondence ID): 236
Comments (Comment ID): 643313

Concern Statement: Consider recent data presented by the State of Nebraska concerning the status of forage fish and body condition of pallid sturgeon.

Response: USACE applied the procedure for addressing significant new information described in the Draft SAMP, and at the direction of and with funding provided by USACE, the United States Geological Survey led a rigorous analysis of pallid sturgeon condition trends (Randall et al. 2017). This report documented declining condition in some lower Missouri River pallid sturgeon and provided recommendations which would narrow the field of hypotheses explaining these conditions. USFWS also identified pallid sturgeon condition as a concern and has recommended a higher priority be given to hypotheses related to declining condition. USACE and USFWS have agreed to advance the recommendations in the pallid condition report, consistent with the process highlighted in the SAMP.

Representative Quotes (Correspondence ID): 207

Comments (Comment ID): 643516

Concern Statement: The information discussing the status of the pallid sturgeon population is misleading and should be checked for accuracy.

Response: The information in this paragraph accurately reflects the conclusions of USFWS as presented in the revised Pallid Sturgeon Recovery Plan (USFWS 2014). A more thorough discussion of the status of pallid sturgeon is presented in Section 3.3.1.1.

Representative Quotes (Correspondence ID): 179

Comments (Comment ID): 645235

Concern Statement: Use of the shovelnose sturgeon as a surrogate species for pallid sturgeon life history characteristics lacks support. The Draft MRRMP-EIS should consider using only what is known about the pallid sturgeon.

Response: Shovelnose sturgeon are only used as a surrogate for pallid sturgeon where the science has identified and supports similarities in the life-history requirements or biology. It is true that there are significant differences between pallid sturgeon and shovelnose sturgeon and using shovelnose sturgeon as a surrogate would not be appropriate for life stages or behaviors where these differences occur.

Comments (Comment ID): 645326

Concern Statement: Volume 2 Page 60 references to the Big Sioux River. It should say the river is in both Iowa and South Dakota as the river is the border between the states.

Response: Text was revised as suggested by the comment.

Representative Quotes (Correspondence ID): 242

Comments (Comment ID): 645591

Concern Statement: According to the scientists working on the river, few hybrids between the pallid and shovelnose sturgeon have been found in the upper river, but are common in the lower river.

Response: Yes. There have only been five pallid x shovelnose hybrids captured in RPMA 2 (Fort Peck Dam to Lake Sakakawea and the lower Yellowstone River). From Gavins Point Dam to the Missouri River mouth (RPMA 4), 238 hybrids have been collected (some of these could be of hatchery origin). Hybrids become more common closer to the mouth of the Missouri River and become very common, even prevalent on the Mississippi River.

EC100 *Environmental Consequences: Pallid Sturgeon*

Concern Statement: There is uncertainty related to pallid sturgeon requirements and the EIS does not reflect the current state of science or that additional science is needed to analyze the effects of the MRRMP-EIS.

Response: USACE and USFWS recognize the results of the Effects Analysis as the best available science on pallid sturgeon. The alternatives development process and subsequent evaluation of impacts to pallid sturgeon was based on the Effects Analysis results. The Draft EIS recognizes the substantial uncertainty that remains relative to cause and effect relationships between management action and pallid sturgeon populations. Adaptive management was included as a component of all alternatives evaluated in the Draft EIS precisely due to the need to implement actions for pallid sturgeon in a manner that reduces uncertainty regarding pallid sturgeon limiting factors.

Representative Quotes (Correspondence ID): 59, 97, 107, 191, 238 242, 245
Comments (Comment ID): 632126, 636850, 644039, 644911, 645992, 645538, 645781

Concern Statement: Limitations related to pallid sturgeon health and life history requirements are not addressed in a timely manner due to the time it takes to gather data and implement new actions under adaptive management.

Response: Poor body condition of pallid sturgeon may be related to a variety of causal factors, such as disease, contaminants, or lack of food; the underlying causes for pallid condition or other health issues may be complex or difficult to discern. The apparent decline in pallid sturgeon body condition may be a short- or long-term condition for the population that will require continued monitoring. Recent data for the lower Missouri River, however, indicates that body condition for the population may be improving. The pace at which an issue like this is addressed through the AM process depends on the urgency and its complexity. One must first identify the factor(s) responsible for the decline in body condition, for example, before it can be addressed. In the case of poor body condition, the independently-conducted analyses made it clear that the cause is unknown.

Representative Quotes (Correspondence ID): 76
Comments (Comment ID): 633563

Concern Statement: The MRRMP-EIS does not include provisions for designation of critical habitat for the endangered pallid sturgeon; for unbalanced reservoirs to address the situation at a particular reservoir; and for the application of the best science currently available. Pallid sturgeon are also affected by habitat loss, fishing and caviar harvesting, entrainment and watercraft propellers, contaminants, hybridization, invasive species, and iridovirus, which are not addressed under any of the alternatives.

Response: Designation of pallid sturgeon critical habitat is not within the jurisdiction of USACE and therefore outside the scope of the proposed action. The effects analysis on which the Draft EIS was based gave consideration to a long list of potential hypotheses related to pallid sturgeon limiting factors. The hypotheses were ranked through a panel of experts as to those most important to the species and the final set of management hypotheses formed the basis for the development of alternatives. However, the adaptive

management process allows for returning to hypotheses that were filtered out should new information provide a reason to do so.

Representative Quotes (Correspondence ID): 81
Comments (Comment ID): 636788

Concern Statement: The return of areas on the Missouri River to more natural habitat will provide habitat for the pallid sturgeon.

Response: The best available science remains inadequate to quantify the effects of physical (abiotic) changes to the Missouri River on pallid sturgeon population dynamics, in spite of the availability of the new information since the 2003 Amended BiOp was issued. Efforts to push beyond a basic understanding of the species' ecology to facilitate predictions of environmental causes and effects on the fish are still compromised by fundamental information gaps. Lines of evidence for many of the pallid sturgeon management hypotheses are limited to theoretical deduction, inference from sparse empirical datasets, or expert opinion. Given the high level of uncertainty regarding the necessary actions to address the listed species' needs, USACE and USFWS agreed that proceeding under a rigorous and progressive SAMP would provide the most effective, efficient, and accountable way to manage risks to the species, address key uncertainties, and identify the scope and scale of actions ultimately required to achieve the MRRP objectives.

Comments (Comment ID): 641587

Concern Statement: The MRRMP-EIS should include further study on the influence of Asian carp on pallid sturgeon.

Response: Asian carp feeding on pallid sturgeon fry has not been documented. While there is the potential for Asian carp to impact various life-history stages of pallid sturgeon, or more likely pallid sturgeon prey, none have been identified as important at this time. Hypotheses related to the predation rate of invasive predators on larval pallid sturgeon were considered through the EA's hypothesis development process, but none were identified as priority hypotheses through a survey of scientific experts. However, these hypotheses are held in reserve and can be considered at a later date. In addition, much work is being done by other entities on Asian carp, and USACE will remain engaged in and aware of those efforts to better understand relevance to pallid sturgeon.

Comments (Comment ID): 643001, 643900

Concern Statement: The MRRMP-EIS should include a description and study of benthic macroinvertebrate food sources.

Response: In the Lower Missouri River, the long-term approach to identifying and implementing management actions and addressing uncertainty is to use the AM process laid out in the MRRMP/EIS. As such, USACE is currently engaged in several studies to better understand the diet and condition of age-0 pallid sturgeon. While the Effects Analysis hypothesized a lack of food may currently be limiting age-0 pallid sturgeon in the Lower Missouri River, Jacobson et al. (2016) also noted that "...the continued growth, recruitment, and survival of shovelnose sturgeon, which are thought to share dietary requirements with pallid sturgeon at this life stage, argue against food as a limiting factor." Information gained through these ongoing studies will help determine if food is limiting to age-0 pallid sturgeon and help identify future research needs.

Representative Quotes (Correspondence ID): 166
Comments (Comment ID): 644889

Concern Statement: Use of the shovelnose sturgeon as a surrogate species for pallid sturgeon life history characteristics lacks support. The Draft MRRMP-EIS should consider using only what is known about the pallid sturgeon and perform additional research.

Response: Shovelnose sturgeon are only used as a surrogate for pallid sturgeon where the science has identified and supports similarities in the life-history requirements or biology. It is true that there are significant differences between pallid sturgeon and shovelnose sturgeon and using shovelnose sturgeon as a surrogate would not be appropriate for life stages or behaviors where these differences occur.

Representative Quotes (Correspondence ID): 238, 242
Comments (Comment ID): 645326, 645541

Concern Statement: The MRRMP-EIS does not explain the benefits of low summer flow in terms of how much shallow water habitat would be created and thus does nothing to prove that it is a beneficial management action for the pallid sturgeon. In addition, low summer flow "would only be implemented in the two years following implementation of a complete bimodal spring pallid sturgeon flow release" which would make implementation infrequent.

Response: The best available science remains inadequate to quantify the effects of physical (abiotic) changes to the Missouri River on pallid sturgeon population dynamics, in spite of the availability of the new information since the 2003 Amended BiOp was issued. Efforts to push beyond a basic understanding of the species' ecology to facilitate predictions of environmental causes and effects on the fish are still compromised by fundamental information gaps. Lines of evidence for many of the pallid sturgeon management hypotheses are limited to theoretical deduction, inference from sparse empirical datasets, or expert opinion. Given the high level of uncertainty regarding the necessary actions to address the listed species' needs, USACE and USFWS agreed that proceeding under a rigorous and progressive SAMP would provide the most effective, efficient, and accountable way to manage risks to the species, address key uncertainties, and identify the scope and scale of actions ultimately required to achieve the MRRP objectives. The low summer flow is part of Alternative 2. The other action alternatives include a range of alternatives that include pallid sturgeon management actions.

Representative Quotes (Correspondence ID): 240

Comments (Comment ID): 645418

Concern Statement: The fall ESH habitat creating release under Alternative 5 is not reflective of the natural historic hydrograph of the Missouri River that may have impacts on pallid sturgeon. Any habitat created through fall releases would suffer serious losses to wind and ice erosion over the winter.

Response: Comment noted.

Representative Quotes (Correspondence ID): 242
Comments (Comment ID): 645521

Concern Statement: The Final MRRMP-EIS should articulate how the success of pallid sturgeon bypassing the Intake Project on the Yellowstone River will be measured.

Response: Monitoring pallid sturgeon bypass at Intake is described in the monitoring and adaptive management plan for the Lower Yellowstone Intake Diversion Dam Fish Passage Project, Montana Final Environmental Impact Statement. That is a separate NEPA process than the Missouri River Recovery Management Plan and not included in the scope of the MRRMP EIS.

Representative Quotes (Correspondence ID): 242
Comments (Comment ID): 645527

Concern Statement: The Draft MRRMP-EIS places too much emphasis on hatchery raised pallid sturgeon. Stocking creates a population that is not self-sustaining and there are concerns with disease and water quality in the hatcheries and the fish raised there. There is also a high cost for hatchery raised pallid sturgeon. More habitat restoration in the upper and lower rivers should be performed to ensure natural production and recruitment.

Response: Implementation of the Pallid Sturgeon Conservation Augmentation Program to date has stabilized the pallid sturgeon population in the Missouri River (USFWS 2014); however, the population is not considered self-sustaining. USACE acknowledges that stocking alone is not a means to avoid jeopardizing pallid sturgeon. However, best available science indicates that inadequate drift distance is the most likely factor limiting pallid sturgeon in the upper Missouri River.

Representative Quotes (Correspondence ID): 242
Comments (Comment ID): 645535

Concern Statement: The MRRMP-EIS should include more research on the possible impacts of agricultural pesticides to determine if any of these chemicals are influencing recruitment of pallid sturgeon or their prey species.

Response: The application, regulation, and potential environmental consequences of agricultural herbicides and pesticides are not under the purview of USACE. If hypotheses that address impacts from agricultural pesticides are identified and prioritized through the AM process, USACE may consider addressing them through research or monitoring since there could be relevance to the effectiveness of planned or ongoing actions and in the interpretations of pallid sturgeon responses to those actions.

Representative Quotes (Correspondence ID): 242
Comments (Comment ID): 645547

Concern Statement: It is questionable if drawdown of Lake Sakakawea would restore desirable riverine habitat needed for larval pallid sturgeon survival and not within the timeframe of the MRRMP-EIS.

Response: The Lake Sakakawea drawdown management action was considered but dismissed from consideration in the Draft EIS. See discussion in Section 2.5.2.1 of the EIS.

Representative Quotes (Correspondence ID): 239
Comments (Comment ID): 645795

Concern Statement: The MRRMP-EIS and the SAMP should discuss competition from non-native fish species.

Response: While competition from non-native fish may impact pallid sturgeon populations, at this time it is not believed to be a primary mechanism that limits recruitment in the Missouri River. In addition, much work is being done by other entities on Asian carp, and we will remain engaged in and aware of those efforts to better understand relevance to pallid sturgeon.

Representative Quotes (Correspondence ID): 107
Comments (Comment ID): 645822

Concern Statement: The Draft MRRMP-EIS only used two years of water temperature data to model downstream of Fort Peck. There is evidence that Fort Peck Dam has substantially affected water temperatures.

Response: Comment noted. USACE acknowledges best available science indicates that water temperatures downstream of Fort Peck dam are suppressed.

Representative Quotes (Correspondence ID): 238
Comments (Comment ID): 645840

Concern Statement: The spring pulse management action, as currently designed, is unnecessary as a cue for spawning pallid sturgeon.

Response: For the Lower Missouri River (i.e., downstream of Gavins Point Dam), the SAMP will explore two competing hypotheses with respect to the role of flows on pallid sturgeon spawning:

1. Pallid sturgeon spawn with or without managed spring flow pulses, and therefore such pulses are not required for spawning (conclusion of the ISAP 2011 report), or
2. Naturalization of the flow releases from Gavins Point Dam will improve flow cues in the spring for aggregation and spawning, increasing reproductive success (a hypothesis evaluated in the recent Effects Analysis).

The lack of evidence of a correlation between flows and pallid sturgeon spawning (hypothesis A) could be due to insufficient numbers of tracked sturgeon, monitoring duration, metrics, and/or contrast in flows. ISAP did not evaluate whether existing spawning was successful or sufficient to maintain the population. Under the proposed SAMP, scientists will evaluate the relationship between pallid sturgeon spawning behaviors and flows in the Missouri River over the next decade to test hypotheses A and B. They will determine whether changes in flow lead to changes in upstream movement, aggregation, and spawning success.

If monitoring provides stronger evidence that flows do act as a spawning cue for pallid sturgeon (support for hypothesis B), then intentionally modifying flows through increased reservoir releases to mimic natural springtime pulses may be implemented in the future to stimulate spawning, increase production of young sturgeon, and help species recovery. Such flow modifications would only occur after the completion of the necessary processes outlined in the SAMP and in accordance with regulation and law, including applicable public involvement requirements.

Comments (Comment ID): 645903

AE200 and AE300 Affected Environment: Piping Plover and Least Tern

Concern Statement: Birds are only seen inside a levee in ponds and pools because habitat riverside of the levee has been destroyed.

Response: The reach of the Missouri River below Ponca, Nebraska includes the Bank Stabilization and Navigation Project which prevents sandbars from developing in the river channel. Nesting of least terns on this reach is rarely recorded, but did occur on sand splays after the 2011 flood and on sediment aggradation areas within the shallow water habitat project on Lower Little Sioux Bend, Iowa. No piping plover nesting activity has been recorded on this reach of the Missouri River since the species was listed.

Representative Quotes (Correspondence ID): 49
Comments (Comment ID): 628666

Concern Statement: The EIS needs to explain why reservoir shorelines are considered intermittent habitat but ESH, which has to be rebuilt, is not considered intermittent habitat.

Response: ESH is considered to be intermittent habitat. See the description of breeding habitat under 3.4.1.1.

Representative Quotes (Correspondence ID): 107
Comments (Comment ID): 643920

EC200 and EC300 Environmental Consequences: Piping Plover and Least Tern

Concern Statement: Attempts to create artificial ESH have had mixed success and have not contributed in any significant way even to the limited population of Piping Plovers using the Gavins Point site; there was no change in number of fledged Piping Plovers there from summer 2000 through summer 2009.

Response: USACE continues to believe that mechanically constructing ESH along with maintaining and/or creating new ESH through vegetation spraying is a viable means to meeting the tern and plover objectives of this Plan. The modeling indicates that persistence probability objectives will not be met without augmenting the ESH created by natural flows. Experience with constructing ESH and maintaining vegetation on natural and constructed sandbars indicates these management actions are achievable and can be successful. It is true that in general the first 3-5 years are the most productive on constructed sandbars, however, this lifetime can be extended through vegetation management.

Representative Quotes (Correspondence ID): 80

Comments (Comment ID): 640100

Concern Statement: Twenty percent of the birds are lost through attrition every year and if there is not nesting for three years 60 percent of the birds are lost.

Response: USACE believes that the Effects Analysis completed for the least tern and piping plover represent the best available science for these species. The model used for this plan was based on the results of the effects analysis. The modeling results provide the MRRP guidance on the amount of ESH that would need to be created to maintain a 95 percent probability of persistence over 50 years. Results of ongoing metapopulation studies could be incorporated into a future iteration of the effects analysis and associated modeling as new information becomes available. The SAMP is designed to react to new information and incorporate into management as needed. Section 3.1.1.1 of the SAMP contains the following statement: “The effects of nearby subpopulations of piping plovers and least terns on Missouri River Mainstem populations (metapopulation dynamics) are not fully understood, and considered a critical uncertainty within the SAMP (Section 3.1.2.5). Studies underway to measure dispersal between the Missouri River Mainstem and other breeding areas will provide information on metapopulation dynamics. As results become available, the ability to account for and model metapopulation dynamics will be evaluated and developed to the extent possible.”

Representative Quotes (Correspondence ID): 52
Comments (Comment ID): 631124

Concern Statement: Alternative 5 is contrary to the natural historic hydrograph of the river. Any habitat created through fall releases would suffer serious losses to wind and ice erosion over the winter. This would create short-lived habitat that would be largely unused while least terns and piping plovers are on their wintering grounds.

Response: The ESH fall flow releases contained within Alternative 5 are designed to benefit least terns and piping plovers by creating new ESH that would last for multiple nesting seasons depending on river conditions. Releasing flows in the fall avoids some impacts associated with spring releases such as flooding existing nests in the spring. ESH created at any time of year would be subject to wind and ice erosion assuming it lasts for multiple nesting seasons. Experience indicates that constructed sandbars last 3-5 years and that lifetime can be extended through vegetation management.

Representative Quotes (Correspondence ID): 242
Comments (Comment ID): 645521

Concern Statement: The statement that the spring emergent sandbar habitat-creating release under Alternative 4 would have relatively large beneficial impacts from the creation of new sandbars that could occur following flows contradicts the conclusion in River Infrastructure and Hydrology which states that Alternative 4 would not have significant impacts on geomorphology. The long-term benefit of the ESH-creating release would only last until the sediment supply was exhausted, or for the inter-dam reaches, until all of the sediment was flushed into the reservoir deltas. Additionally, the ESH-creating release in the spring would have an adverse effect by increasing the flood risk of birds nesting on sandbars. This risk should be recognized in the MRRMP-EIS.

Response: The sandbar habitat-creating release under Alternative 4 would have relatively large beneficial impacts to piping plovers and least terns in comparison to Alternative 1 due to

increased amounts of ESH available to terns and plovers. The long-term impacts to geomorphology (i.e., exhausting the sediment supply) are not anticipated to be significant within the 50-year planning horizon of this plan. As stated in Section 3.2.2.4 degradation from ESH creating releases was projected to be on the order of up to 6 inches in the mid-section of the Garrison Dam to Lake Oahe reach for each release. Modeling indicates that ESH releases could only occur once every 7-10 years. The Final EIS acknowledges that the spring flows would create a higher risk of flooding for birds nesting on sandbars.

Representative Quotes (Correspondence ID): 239
Comments (Comment ID): 645400

Concern Statement: A section should be added to the MRRMP-EIS and SAMP on possible impacts related to piping plover science and management actions pending the results of the metapopulation study.

Response: Results of ongoing metapopulation studies could be incorporated into a future iteration of the effects analysis and associated modeling as new information becomes available. The SAMP is designed to react to new information and incorporate into management as needed. Section 3.1.1.1 of the SAMP contains the following statement: “The effects of nearby subpopulations of piping plovers and least terns on Missouri River Mainstem populations (metapopulation dynamics) are not fully understood, and considered a critical uncertainty within the SAMP (Section 3.1.2.5). Studies underway to measure dispersal between the Missouri River Mainstem and other breeding areas will provide information on metapopulation dynamics. As results become available, the ability to account for and model metapopulation dynamics will be evaluated and developed to the extent possible.”

Representative Quotes (Correspondence ID): 148, 229
Comments (Comment ID): 644900, 642694

Concern Statement: A re-evaluation of the modeling of the chance of persistence of piping plovers and least terns over 50 years should be performed. The statement under Alternative 1, that it appears the alternative would not meet the 95 percent chance of persistence over 50 years, is not supported because plovers and terns have maintained a population since closure of the last dam on the Missouri system in 1967. The facts do not support the modeling results. Additionally, modeling the Missouri River as two separate piping plover populations, Northern and Southern, with little interactions and holding emigration and immigration steady an equal in the models does not take into account the bigger metapopulation influence and has limitations. The MRRMP-EIS should include a graph or table that demonstrates the historical relationship of plover populations to acres of emergent sandbar habitat in the past.

Response: The approach of evaluating long-term persistence probabilities is conducted in recognition that there are many potential outcomes for dynamic habitat and populations. These outcomes depend on factors that are highly variable and difficult to predict, such as annual weather patterns and long-term climate trends. The historical dynamics of piping plovers depended on many factors including the frequency, timing, and magnitude of ESH-forming flows and drought periods. Future persistence depends, in part, on these factors which may or may not repeat past patterns. The objective of USFWS is to identify an acceptable level of risk. In this case, they have determined that an undesirable outcome of extirpation of plovers on the Missouri River should occur in no more than 1 of 20 potential futures. In some potential futures, plovers may persist without additional

management, but USFWS requires that probability to be 95 percent. In addition, changes to the morphology and sediment dynamics of the river may reduce the likelihood that future habitat and population dynamics will reflect the past, particularly the time shortly after dam closure.

Recently collected information about metapopulation processes was not available during the development of alternatives for the Draft EIS. This information will be incorporated to the extent possible in ongoing modeling and evaluation as part of the SAMP.

Representative Quotes (Correspondence ID): 107
Comments (Comment ID): 643921, 643807

Concern Statement: The MRRMP-EIS should discuss the limitations, assumptions, and caveats associated with the piping plover modeling, including that the model of emergent sandbar habitat deposition and erosion is new and based on a limited time frame; and that the population models are parameterized using current condition with a limited time of 2005-2014 for riverine habitat. The models do not consider metapopulations and differ from the models used by the piping plover Recovery Team.

Response: Limitations and assumptions associated with the modeling are provided in *Modeling to Support the Development of Habitat Targets for piping plovers on the Missouri River*, (Buenau 2016). These documents are available at www.moriverrecovery.org. The Final EIS refers the reader to this document which was available along with the Draft EIS during the public comment period.

Comments (Comment ID): 643806, 641605

Concern Statement: Temporary and long-term impacts to geomorphology in the Draft MRRMP-EIS from spawning cue releases could affect the availability of materials for piping plover habitat.

Response: The long-term impacts to geomorphology (i.e., exhausting the sediment supply) are not anticipated to be significant within the 50-year planning horizon of this plan. As stated in Section 3.2.2.4 degradation from ESH creating releases was projected to be on the order of up to 6 inches in the mid-section of the Garrison Dam to Lake Oahe reach for each release. Modeling indicates that ESH releases could only occur once every 7 to 10 years.

Representative Quotes (Correspondence ID): 107
Comments (Comment ID): 643908

Concern Statement: Least tern has been impacted by past actions on the Missouri River. Management actions proposed will provide an opportunity to return sections of the river to more natural habitat and provide habitat for least tern.

Response: The impacts analysis presented in Chapter 3 of the Final EIS indicates all of the alternatives except for the No Action alternative meet the objectives for the least tern.

Representative Quotes (Correspondence ID): 190
Comments (Comment ID): 641587

Concern Statement: Any habitat created through fall releases would suffer serious losses to wind and ice erosion over the winter. This would create short-lived habitat that would be largely unused while least terns and piping plovers are on their wintering grounds.

Response: The ESH fall flow releases contained within Alternative 5 are designed to benefit least terns and piping plovers by creating new ESH that would last for multiple nesting seasons depending on river conditions. Releasing flows in the fall avoids some impacts associated with spring releases such as flooding existing nests in the spring. ESH created at any time of year would be subject to wind and ice erosion assuming it lasts for multiple nesting seasons. Experience indicates that constructed sandbars last 3-5 years and that lifetime can be extended through vegetation management.

Representative Quotes (Correspondence ID): 242
Comments (Comment ID): 645521

Concern Statement: Restoring sandbars along the Iowa section of the Missouri River will help restore the least tern populations.

Response: The reach of the Missouri River below Ponca, Nebraska includes the Bank Stabilization and Navigation Project which prevents sandbars from developing in the river channel. The Iowa section of the Missouri River is all within the BSNP reach. Nesting of least terns on this reach is rarely recorded, but did occur on sand splays after the 2011 flood and on sediment aggradation areas within the shallow water habitat project on Lower Little Sioux Bend, Iowa. No piping plover nesting activity has been recorded on this reach of the Missouri River since the species was listed. Many of the same uncertainties existing for reservoir and sandpit habitats exist for habitat in this geographic area. The value of this habitat to piping plover and least tern reproduction is unknown. Habitat preference sand dispersal, forage availability, land acquisition, feasibility of creation and maintenance would all need to be resolved. Considering these uncertainties, USFWS has recommended USACE not spend resources on purposefully developing habitat below Ponca, Nebraska as a management action in the EIS at this time.

Comments (Comment ID): 641605

AE400 *Affected Environment: Fish and Wildlife Habitat*

Concern Statement: Asian carp impact many other fish species through stress, competition of foraging areas and river spaces, predation, and change the balance of the river species community. This issue should be addressed in the Final MRRMP-EIS.

Response: While competition from non-native fish may impact pallid sturgeon populations, at this time it is not believed to be a primary mechanism that limits recruitment in the Missouri River. In addition, much work is being done by other entities on Asian carp, and we will remain engaged in and aware of those efforts to better understand relevance to pallid sturgeon.

The impacts from non-native/invasive species to fish and wildlife were described in Section 3.5.2.10 Invasive Species and based on the potential for their introduction or spread from any of the management actions. Impacts from invasive aquatic species would decrease from implementation of the USFWS Aquatic Invasive Species Program with benefits expected from monitoring habitats to determine the distribution of invasive species, rapidly responding to new invasions, and controlling established populations. Additionally, management actions would be performed in accordance with Executive Order 13122, federal agencies may not authorize, fund, or carry out actions that are likely to cause or promote the introduction or spread of invasive species. Any

management actions taken would be evaluated on a site-specific level to ensure that compliance with Executive Order 13122 is met. It is not expected that any invasive aquatic wildlife species would spread because of any of the management actions.

Representative Quotes (Correspondence ID): 179
Comments (Comment ID): 645223

Concern Statement: The Draft MRRMP-EIS does not appear to consider changes to vegetation due to conversion of grassland to cropland and has not calculated the effects on floodplain connectivity for fish and wildlife habitat classes.

Response: Past, present, and future conversion of grassland to cropland and loss of floodplain connectivity is discussed in Section 3.5.2.14 Cumulative Impacts, the cumulative impacts assessment for fish and wildlife.

Representative Quotes (Correspondence ID): 166
Comments (Comment ID): 644881

EC400 *Environmental Consequences: Fish and Wildlife Habitat*

Concern Statement: The MRRMP-EIS should consider other species that are at risk for endangerment due to Missouri River management as well as the impacts from non-native/invasive species. Management actions would also benefit non-listed species including important sportfish and improve the overall fish community.

Response: A total of 126 species that have been given special status at either the federal or state level and may occur within the geographic scope of the program were evaluated in the MRRMP-EIS. These species include 18 plants, 31 birds, 12 mammals, 17 reptiles and amphibians, 23 fish, 21 mussels and gastropods, and 4 insects. All species were initially assessed to determine if they should be evaluated in detail; those species not selected for detailed analysis are listed in Appendix E. In this appendix, the potential impacts to each special status species are recognized based upon predetermined criteria. After consultation with USFWS, three species from the list of 126 were selected for detailed analysis based on the potential for impacts that could occur to individuals, populations, or their habitats in areas where management actions might occur. These five species include: bald eagle, northern long-eared bat, and Indiana bat.

The impacts from non-native/invasive species to fish and wildlife were described in Section 3.5.2.10 Invasive Species and based on the potential for their introduction or spread from any of the management actions. Impacts from invasive aquatic species would decrease from implementation of the USFWS Aquatic Invasive Species Program with benefits expected from monitoring habitats to determine the distribution of invasive species, rapidly responding to new invasions, and controlling established populations. Additionally, management actions would be performed in accordance with Executive Order 13122, federal agencies may not authorize, fund, or carry out actions that are likely to cause or promote the introduction or spread of invasive species. Any management actions taken would be evaluated on a site-specific level to ensure that compliance with Executive Order 13122 is met. It is not expected that any invasive aquatic wildlife species would spread because of any of the management actions.

The impacts to the sport fisheries were described qualitatively in Section 3.5.2.11 Commercial Fisheries in the Final EIS.

Comments (Comment ID): 626266, 645830, 645797, 645794, 645571, 641670, 641596, 641594, 636793

Concern Statement: USACE and the State of Montana must develop guidance on how mitigation in the connected Missouri River and Yellowstone River ecosystem will mitigate for impacts to other native fish and wildlife species and this should be included in the Final MRRMP-EIS. Mitigation could be included as part of the SAMP and their inclusion could be used as Level 3 and Level 4 studies.

Response: Mitigating for impacts to fish and wildlife species beyond the three ESA listed species is beyond the scope of this Plan although it is likely that actions taken for endangered species would have incidental benefits to other native fish and wildlife species as described in Section 3.5.2 Environmental Consequences of the Final EIS.

Representative Quotes (Correspondence ID): 236
Comments (Comment ID): 646302

Concern Statement: Hydropeaking during flow pulse events could exasperate the effect of dewatering aquatic habitats. Steady pulses from Fort Randall Dam would minimize the dewatering of aquatic habitats in this reach.

Response: Through the adaptive management process the effects of flow pulse events would be documented and if issues related to dewatering of aquatic habitats were observed to exist the impacts to species, including other native fish species, would be evaluated and appropriate mitigation measures implemented. The preferred alternative includes only the possibility of a one-time flow test from Gavins Point and does not include re-occurring flow changes that would exacerbate the effects of dewatering.

Representative Quotes (Correspondence ID): 206
Comments (Comment ID): 645982

Concern Statement: Significant drawdown of Lake Sakakawea would have devastating consequences to the fishery. Sixty years of fisheries research by North Dakota Game and Fish Department has confirmed that maintaining an adequate water level (absolute minimum of 1,825 msl) and having a rising pool during the spring spawning and egg incubation period are critical for maintaining the number one most used fishery in North Dakota - Lake Sakakawea.

Response: USACE understands that maintaining reservoir elevations and increasing reservoirs elevations in the spring is important to maintain the fishery at the upper three reservoirs. USACE staff have spoken with North Dakota Game and Fish supervisory level staff several times to discuss these issues and have read the Fisheries Management Plans for the Missouri River System. A fishing success proxy metric was developed, which is described in Section 2.4 of the "Recreation Environmental Consequences Analysis Technical Report," and is based on input from fisheries biologists, including North Dakota Game and Fish staff. Additional description of the potential impacts to the fishery if criteria noted in the fisheries management plans are not met was added to the Final EIS under alternatives with proposed releases in Section 3.5 Fish and Wildlife Habitat.

Representative Quotes (Correspondence ID): 239
Comments (Comment ID): 645796, 642846, 642843

Concern Statement: Sandbar habitat creating flows have the potential to severely impact the sport fishery of Lewis and Clark Lake. Both the spring and fall releases would result in

decreased walleye abundance in the Lewis and Clark Lake. The impact of a fall release and a May release on walleye would likely result in entrainment of a large percentage of newly hatched walleye. Major flow events also have the ability to flush the majority of pelagic prey (rainbow trout and lake herring) and Chinook salmon through Oahe Dam. Even if reservoir elevations are sufficient to allow good access to the reservoir after major flow events, the lack of available food resources results in the loss of the larger walleye from the reservoir due to starvation. Decreasing elevation of Lake Oahe and Francis Case during prey and game fish spawning periods (April - June) is a concern as stable-to-rising elevations are important to the success of prey fish and sportfish spawning events and egg incubation. With Lake Oahe being the lowest of the big-three storage reservoirs in the system, a spring release to create ESH will certainly remove the possibility of favorable conditions for spawning during the year of the flow implementation.

Response: The impacts to the sport fisheries described in these comments and concern statement, including the impacts to the fishery from flow events in Lake Oahe, Lewis and Clark Lake, and Lake Francis Case, are described qualitatively in the recreation in the Final EIS in Section 3.5.16 Environmental Consequences.

Representative Quotes (Correspondence ID): 206

Comments (Comment ID): 645143, 645786, 645147, 645129

Concern Statement: Low summer flows may increase the likelihood of zebra mussel juveniles settling out of the water column and attaching to water intake systems.

Response: Information related to the potential increase of zebra mussel juveniles attaching to water intake systems as a consequence of low summer flows was added to the Final EIS. Specific mitigation measures would be included in site specific documents related to invasive species as those projects are developed.

Representative Quotes (Correspondence ID): 206

Comments (Comment ID): 645753

Concern Statement: The use of herbicide use during vegetation removal on emergent sand habitat could potentially impact birds, mammals, and invertebrates. Aerial spraying and herbicide drift to fish and wildlife could cause impacts as well. More research should be performed on the potential impacts of agricultural pesticides to determine if any of these chemicals are influencing pallid sturgeon prey species.

Response: The Final EIS includes information on the potential impacts from herbicide use during vegetation removal in Section 3.5.2.3 Vegetation Management, Predator Management, and Human Restriction Measures. Although herbicides could enter the substrate when vegetation is removed during vegetation management operations, only herbicides approved by the U.S. Environmental Protection Agency for aquatic use would be applied at the recommended rates. If hypotheses that address impacts from agricultural pesticides are identified and prioritized through the AM process, USACE may consider addressing them through research or monitoring since there could be relevance to the effectiveness of planned or ongoing actions and in the interpretations of pallid sturgeon responses to those actions.

Representative Quotes (Correspondence ID): 242

Comments (Comment ID): 645547

Concern Statement: Alternative 5 does not reflect the natural historic hydrograph of the Missouri River and any habitat created during fall releases would suffer serious losses due to wind and ice erosion over the winter. Such a large release at an unnatural time of the year could have impacts on native fish species.

Response: Emergent sandbar habitat created in spring would be exposed to the same wind and ice erosion as ESH created in the fall. Typically, ESH lasts from 5 to 10 years depending on river conditions.

Representative Quotes (Correspondence ID): 242
Comments (Comment ID): 645521

Concern Statement: The importance of timely water level manipulation for fish and wildlife resource management cannot be over-emphasized, nor can the destructive capacity of untimely manipulation be underestimated. Correlation analyses of the total catch rate of young-of-the-year (YOY) fish (all Sakakawea) and environmental variables show significant positive correlations between catch rates of YOY fish and spring rise, total rise, and the change in maximum water levels from the previous year (Table 3). These data indicate the importance of water level management to the overall reproduction of fish in Lake Sakakawea.

Response: Information discussing the dependence of reservoir fishery health on water levels and the importance of water level management to the overall production of fish in Lake Sakakawea was added to Sections 3.5.1 Affected Environment and 3.5.2 Environmental Consequences of the Fish and Wildlife Section of the Final EIS.

Representative Quotes (Correspondence ID): 239
Comments (Comment ID): 645385

Concern Statement: Any adjustments to Fort Peck should also include considerations for life cycle needs and turbidity in the health of native fish species.

Response: Concur; however, modification to the operation of Fort Peck Dam is not a management action included within the alternatives. In recognition of the scientific uncertainty surrounding Fort Peck flow adjustments, USACE agreed to formulate test flows from Fort Peck and an AM framework for their implementation during formal ESA Section 7 consultation on this plan. Studies under the framework may include additional drift studies, tracking of fish and documentation of spawning locations, telemetry evaluations and methodology improvements, risk analysis, and engineering studies. Implementation of an identified hydrograph to test hypotheses would be considered; however, depending on the specifics of the test hydrograph, may be outside the scope of this EIS.

Representative Quotes (Correspondence ID): 238
Comments (Comment ID): 645339

Concern Statement: It is not clear if the fish and wildlife modeling can detect basic differences of land cover and land use by spatial location or if the models have been validated through ground truthing. It is impossible to assess the ecosystem values from an assessment of inundation based on flow and depth.

Response: The fish and wildlife modeling does not detect absolute differences of land cover and land use by spatial location. The analysis is useful for comparing trends between alternatives (e.g., trending toward wetter or drier habitats), but should not be used as an indicator of absolute changes or shifts in habitat classes. The impacts analysis assumes

that changes in specific day inundation regimes are representative of the trends that would occur under each alternative. The fish and wildlife modeling was intended to estimate changes in vegetation classes under each alternative rather than measure ecosystem values. More detailed information is included in the “Fish and Wildlife Environmental Consequences Analysis Technical Report.”

Representative Quotes (Correspondence ID): 166
Comments (Comment ID): 644883

Concern Statement: The impacts from vegetation management actions to native plant communities, such as cottonwood, and non-listed species in the Missouri National Recreation River should be addressed.

Response: As described in Sections 6.1.1 of the MRRMP-EIS, USACE understands it requirements under Section 7 of the Wild and Scenic Rivers Act and is committed to complying with the law related to construction actions contemplated within the Missouri River National Recreation River.

Representative Quotes (Correspondence ID): 183
Comments (Comment ID): 643953

Concern Statement: If lower elevations in reservoirs result in fish dying it would take years to recover and will not dissipate within a year as described in the Draft MRRMP-EIS. The importance of timely water level manipulation for fish and wildlife resource management cannot be overemphasized, nor can the destructive capacity of untimely manipulation be underestimated.

Response: USACE understands that maintaining reservoir elevations and increasing reservoirs elevations in the spring is important to maintain the fishery at the upper three reservoirs. USACE staff have spoken with North Dakota Game and Fish supervisory level staff several times to discuss these issues and have read the Fisheries Management Plans for the Missouri River System. A fishing success proxy metric was developed, which is described in Section 2.4 of the “Recreation Environmental Consequences Analysis Technical Report,” based on input from fisheries biologists, including North Dakota Game and Fish staff. Additional description of the potential impacts to the fishery if criteria noted in the fisheries management plans are not met was added to the Final EIS under alternatives with proposed releases in Section 3.5 Fish and Wildlife Habitat.

Representative Quotes (Correspondence ID): 239
Comments (Comment ID): 642709, 642707

Concern Statement: The analysis of the alternatives does not contain commercial fishing data and the economic analysis is deficient.

Response: USACE does not believe the economic analysis of commercial fishing contained within the EIS is deficient due to the lack of information. CEQ’s NEPA regulations state that data and analyses included in an EIS should be commensurate with the importance of the impact (40 CFR 1502.15). A qualitative discussion of the potential commercial fishing impacts resulting from the alternatives was included in the Draft EIS. USACE has determined that the alternatives would have a negligible impact on commercial fisheries and a detailed economic analysis of commercial fishing is not warranted. Commercial fishing is covered in Sections 3.5.2.8 and 3.5.2.11 of the Final EIS.

Representative Quotes (Correspondence ID): 76
Comments (Comment ID): 633560

Concern Statement: The rises under Alternatives 4 and 5 increase backwaters, roosting and feeding areas for migrating birds, eagles, and waterfowl of all kinds, increase hunting opportunities, and improve revenues for towns and communities.

Response: These benefits are described in the Final EIS in Section 3.5.2.7 Alternative 4 – Spring ESH Creating Release and 3.5.2.8 Alternative 5 - Fall ESH Creating Release Environmental Consequences for fish and wildlife and in Section 3.16.2 Environmental Consequences for recreation.

Representative Quotes (Correspondence ID): 50
Comments (Comment ID): 628620

AE500 ***Affected Environment: Other Special Status Species***

Concern Statement: The EIS needs to consider other listed species, including state threatened and endangered species, and species that have the potential to decline further and make the most out of rehabilitation projects and habitat creation, including the Bank Stabilization and Navigation Project, to also benefit numerous species.

Response: A total of 126 species that have been given special status at either the federal or state level and may occur within the geographic scope of the program were evaluated in the MRRMP -EIS. These species include 18 plants, 31 birds, 12 mammals, 17 reptiles and amphibians, 23 fish, 21 mussels and gastropods, and 4 insects. All species were initially evaluated to determine if they should be evaluated in detail; those species not selected for detailed analysis are listed in Appendix E. In this appendix, the potential impacts to each special status are recognized based upon predetermined criteria. After consultation with USFWS, three species from the list of 126 were selected for detailed analysis based on the potential for impacts that could occur to individuals, populations, or their habitats in areas where management actions might occur. These three species include: bald eagle, northern long-eared bat, and Indiana bat. The impacts to these three species were fully evaluated in the EIS, including the adverse and beneficial effects from implementation of management actions for each alternative considered.

Representative Quotes (Correspondence ID): 147, 177, 179, 224
Comments (Comment ID): 640691, 644406, 644621, 645224

EC500 ***Environmental Consequences: Other Special Status Species***

Concern Statement: The Draft MRRMP-EIS should consider other listed species, including state listed species and candidate species, and those that are at risk of becoming listed species.

Response: A total of 125 species that have been given special status at either the federal or state level and may occur within the geographic scope of the program were evaluated in the MRRMP -EIS. These species include 18 plants, 31 birds, 11 mammals, 18 reptiles and amphibians, 23 fish, 20 mussels, and 4 insects. All species were initially evaluated to determine if they should be evaluated in detail; those species not selected for detailed analysis are listed in Appendix E. In this appendix, the potential impacts to each special status are recognized based upon predetermined criteria. After consultation with USFWS, five species from the list of 125 were selected for detailed analysis based on the potential for impacts that could occur to individuals, populations, or their habitats in areas where management actions might occur. These five species include: whooping

crane, bald eagle, northern long-eared bat, Indiana bat, and western prairie fringed orchid.

AE600 ***Affected Environment: Water Quality***

Concern Statement: Statements in the Draft MRRMP-EIS concerning other pollutants in the water quality section are concerning. Water services in Kansas City routinely treats for atrazine removal to meet potable water contaminate levels and treats for Taste and Odor compounds.

Response: USACE concurs; the statements in Section 3.7.1.3 are simply restating facts originally highlighted in other references to describe components that are present in Missouri River water. The fact that water services in Kansas City routinely treats for atrazine, for example, shows that this compound is present in the water. The statements in Section 3.7.1.3 state that most of the compounds, especially atrazine, are not problematic and that levels do not exceed water quality criteria.

Representative Quotes (Correspondence ID): 204
Comments (Comment ID): 644455

Concern Statement: A tabular listing of Total Maximum Daily Load (TMDL), by state, would provide the public with an awareness of environmental conditions on the Missouri River that may be contributing or competing sources of jeopardy for the endangered species.

Response: USACE concurs; the TMDL reports would provide awareness of environmental conditions on the Missouri River; however, a list of all TMDLs associated with the river was outside the substantive scope of the EIS. The main goal of the water quality affected environment section (Section 3.7.1) is to concentrate the discussion on the parameters of most importance to the river and, specifically, those which would be affected by the alternatives. Throughout Section 3.7.1, the paragraphs titled “Other Pollutants” provide additional description of water quality parameters in each reach.

Representative Quotes (Correspondence ID): 166
Comments (Comment ID): 644920

Concern Statement: The list of water quality parameters discussed should include pH.

Response: The purpose of Section 3.7, Water Quality is to focus the analysis on the main parameters that would describe the existing conditions in the river and, specifically, those which would be affected by the alternatives. The water quality data available for analysis indicated most recorded pH values were within state limits with the exception of a few outliers.

Representative Quotes (Correspondence ID): 239
Comments (Comment ID): 645405

EC600 ***Environmental Consequences: Water Quality***

Concern Statement: Alternative 3 has the potential to violate water quality standards during mechanical ESH construction from release of trace elements, during Level-2 in-river

testing from loss of cold water habitat in Lake Sakakawea, and during implementation of Level 3 and 4 actions of the SAMP.

Response: Section 3.7.2 Water Quality Environmental Consequences acknowledges that mechanical construction could temporarily impact water quality by increasing nutrients, sediment and turbidity, and other pollutants and potentially decreasing dissolved oxygen concentrations. However, the water quality impacts would be temporary and localized to the area of construction and a short distance downstream. Measures would be taken to minimize and prevent these impacts and the amount of mechanical ESH construction would be limited to only the amount that is necessary to meet the bird habitat targets after accounting for available ESH. Adherence to best management practices during construction would minimize or eliminate the risk of unintended water quality effects from discharged sediment and turbidity, nutrients, and other pollutants. Each site-specific construction project would comply with Sections 401, 402, and 404 of the Clean Water Act (CWA) and applicable water quality standards through site-specific analysis and coordination. As discussed in Section 3.7.2 and Section 6.3.1, USACE would regulate any discharges of dredge or fill material into waters of the United States, including the Missouri River, pursuant to Section 404 of the CWA. The selection of disposal sites for dredged or fill material would be done in accordance with the Section 404(b)(1) guidelines. Section 401 water quality certifications would be obtained for site-specific management actions, as required, prior to construction. The certification requires a finding by the affected states that the activities permitted would comply with all water quality standards individually or cumulatively over the term of the permit. USACE will conduct testing of material for contaminants prior to using those materials for in-river ESH construction. Furthermore, site-specific NEPA analysis would take place to identify potential issues, including to water quality.

Level 2, 3, and 4 actions contained within the SAMP such as low flows from Fort Peck or drawdowns of Lake Sakakawea are outside the scope of the preferred alternative and would need an additional or supplemental NEPA process before implementing.

Representative Quotes (Correspondence ID): 3, 96
Comments (Comment ID): 645650, 640264

Concern Statement: The Draft MRRMP-EIS and the SAMP lack the details that identify the limits of hydraulic modification that could occur and the lack of a clear process to consult the state being affected by the decision-making process in implementing the SAMP. The MRRMP-EIS implies that under the SAMP the unidentified decision-makers will have science-based options to implement regardless of water quality consequences in the upper basin. North Dakota cannot support Alternative 3 without inclusion of specific boundaries in the SAMP that would protect existing beneficial uses and support water quality standards.

Response: Any actions outside of the selected alternative in the Final EIS and Record of Decision would need additional state coordination and an additional or supplemental NEPA process before being implemented. The process for state coordination is presented in the Governance section of the Final SAMP.

Representative Quotes (Correspondence ID): 3
Comments (Comment ID): 645651

Concern Statement: Anti-resistant microbes in soils on the riverbanks have not been considered. This in combination with water use is a concern.

Response: The purpose of the larger Section 3.7 Water Quality and Section 3.7.2 Water Quality Environmental Consequences is to analyze potential impacts from implementation of the alternatives on the primary listed parameters. Although antibiotic resistant bacteria could be present in riverbank soils along the Missouri River, USACE determined the most appropriate method to assess water quality impacts was to use the selected parameters.

Representative Quotes (Correspondence ID): 70
Comments (Comment ID): 631226

Concern Statement: Nutrient loading should be given more consideration in the MRRMP-EIS. Blue-green algae is harmful to aquatic life. Additionally, any flow regime with the potential to create conditions optimal for blue-green algal growth is a concern including low flows in summer that would have a negative impact on water quality. Limited observed temperature data was available causing inaccuracies in modeled temperature changes for the alternatives and a loss of confidence in the Water Quality Technical Report. Low flows in summer would impact water quality with high delivered water temperatures and potential for algal blooms with warmer river temperatures to increase incubation or growth of any organic organism. These would require higher concentrations of additional chemicals.

Response: Section 3.7 Water Quality provides much consideration to nutrient loading including descriptions of existing conditions in Section 3.7.1 and discussion of impacts under each alternative in Section 3.7.2. In Section 3.7.2, increased nutrient loading is discussed in relation to various actions under each alternative; however, the increase in nutrients from these actions are negligible or small compared to the river as a whole and the overall nutrient loading to the river from all sources. Both point and nonpoint source nutrient loading from other land uses along the Missouri River such as agricultural, urban, and industrial areas and from tributaries are not covered under this effort, and these sources discharge the majority of the nutrient load to the river as compared to the actions proposed under each alternative. It is understood that blue-green algae has proliferated in other waterbodies under low flow conditions; however, through experience USACE researchers have indicated this is not likely to occur on the lower Missouri River. The lower Missouri River is channelized and narrowed, and reducing flows will not impact water temperatures as much as they might in a braided river habitat. The river water levels would have to drop to a very low level for blue-green algae to become problematic. Only Alternative 2 proposes a low flow feature but because low flow is not expected to cause a blue-green algae issue, it was not discussed in the impact analysis in Section 3.7.2.5.

Comments (Comment ID): 645778, 645760, 644709, 646280, 645755, 642119, 643417, 645484, 638507, 628465

Concern Statement: State and federal agencies should be held to the same standards as agricultural and urban constituents with respect to reducing nutrient transport by way of our rivers and streams, and the practice of placing nutrient-laden sediment into the river channel will only add to the challenge of improving water quality in Iowa and downstream. Any mechanical habitat construction should be undertaken in a manner that avoids, to the greatest extent possible, deposition of sediment back into the Missouri River.

Response: As discussed in Section 6.3.1 and under alternatives in Section 3.7.2, USACE will regulate any discharges of dredge or fill material into waters of the United States, including the Missouri River, pursuant to Section 404 of the Clean Water Act (CWA). The selection of disposal sites for dredged or fill material will be done in accordance with the Section 404(b)(1) guidelines. Section 401 of the CWA allows states to grant or deny water quality certification for any activity that results in a discharge into waters of the United States and requires a federal permit or license. Certification requires a finding by the affected states that the activities permitted would comply with all water quality standards individually or cumulatively over the term of the permit. Section 401 water quality certifications would be obtained for site-specific management actions, as required, prior to construction. Each process will include compliance with Sections 401, 402, and 404 of the Clean Water Act and applicable water quality standards through site-specific analysis and coordination. Furthermore, site-specific NEPA analysis would take place to identify potential issues, including to water quality.

Representative Quotes (Correspondence ID): 224
Comments (Comment ID): 644409

Concern Statement: Water from Kansas reservoirs should not be used to support the alternatives presented in the MRRMP-EIS. Water quality should be should be considered one of the highest priorities with substantial impacts to human considerations.

Response: The preferred alternative does not include re-occurring flow modifications for endangered species. Alternative 3 includes the possibility of a one-time flow test from Gavins Point Dam for pallid sturgeon after 9 years if determined to be necessary. USACE will attempt to avoid impacts to Kansas reservoirs if a flow-test is necessary.

Representative Quotes (Correspondence ID): 219
Comments (Comment ID): 643493

Concern Statement: Releases from ESH construction can be managed by pre-construction sampling to identify sites with acceptable levels of pollutants and the development of a series of sediment management practices that would reduce any water quality violation to an acceptable volume and distance as a percentage of the river system.

Response: USACE concurs; construction will be guided by compliance with National Pollutant Discharge Elimination System (NPDES) permits, Clean Water Act (CWA) Section 401 water quality certification, CWA Section 404 authorization, and by using construction best management practices to minimize and prevent pollutant loading as discussed in Section 6.3.1 and throughout Section 3.7.2. At each site, elutriate testing will be performed before construction to test materials for contaminants. Furthermore, site-specific NEPA analysis would take place to identify potential issues, including water quality.

Representative Quotes (Correspondence ID): 96
Comments (Comment ID): 640273

Concern Statement: Mechanical habitat construction has the potential to liberate pollutants into the Missouri River that exceed the state's acute and chronic water quality standards criteria. The MRRMP-EIS does not identify any of the potential pollutants, or provide a solution to address them.

Response: Although the potential is there, the release of pollutants from mechanical habitat construction would likely be very small. As noted in Section 3.7.1, previous elutriate testing at specific sites has revealed that metal/metalloid concentrations from excavated or dredged material is less than existing water quality criteria and not considered problematic. Given the programmatic nature of this document, specific construction sites are not identified at this time. Therefore, the potential pollutants present at each site, if any, are unknown. Site-specific analysis would need to be conducted at each site prior to construction as discussed in Section 6.3.1. Solutions to minimize and prevent pollutant loading during mechanical habitat construction would also be specific to each site. In general, adverse impacts to water quality would be minimized or eliminated during mechanical habitat construction sites through by compliance with National Pollutant Discharge Elimination System (NPDES) permits, CWA Section 401 water quality certification, CWA Section 404 authorization, and by using construction best management practices. Site-specific projects would perform elutriate testing on materials to test for contaminants before beginning construction. Mitigation measures would need to be designed and prepared following site-specific analysis as discussed in Section 6.3.1.

Comments (Comment ID): 640272, 640268

Concern Statement: USACE fails to give adequate consideration of ecosystem services and that failure impacts their evaluation of alternatives. USACE fails to give adequate clean water services to acquired acres or benefits to groundwater recharge.

Response: The discussion concerning water quality impacts from early life stage habitat for pallid sturgeon and habitat development actions was revised in Section 3.7.2 of the Final MRRMP-EIS. The revisions describe the beneficial long-term impacts resulting from the removal of acreage from land uses (e.g., agricultural, industrial) that typically have adverse impacts on water quality including the associated reduction in pollutant loading to the river. Beneficial impacts resulting from the water filtration services provided by the acquired land is already discussed in the paragraphs analyzing the impacts of habitat development. Section 3.23, Ecosystem Services, discusses the impacts of creating natural habitats and acquiring and restoring land on the provision of clean water and groundwater recharge services.

AE900 *Affected Environment: Cultural Resources*

Concern Statement: The Great Plains Water Alliance Tribes are not signatories to the Missouri River Programmatic Agreement, and thus full compliance with Section 106 and the implementing regulations at 36 CFR Part 800 is mandatory. USACE Section 106 procedures are widely considered to violate 36 CFR Part 800. The Draft MRRMP-EIS does not consider that frequently historic properties of religious and cultural significance are located on ancestral, aboriginal, or ceded lands of Indian Tribes when complying with this part. 36 CFR §800.2(c)(2)(ii)(D). The surveys used for the computer models are outdated, and were not conducted in compliance with the consultation requirements for traditional cultural properties 36 CFR §800.2(c)(2)(ii). The inventory of known cultural resource sites used in the analysis is a representative sample and many unknown cultural resources sites exist on the landscape. That does not constitute compliance with

the identification requirements of 36 CFR 36 CFR §§800.2-800.5. Consequently, the Draft MRRMP-EIS violates the National Historic Preservation Act and its implementing regulations.

Response: USACE is dedicated to open communication and consultation in regards to fostering conditions that contribute to the preservation of historic properties. Consultation to assess the context and intensity of impacts to cultural resources including historic structures, archaeology sites, or other historic properties of religious or cultural significance to Native American Tribes has been conducted throughout the process and is ongoing. The existing cultural resource survey data were utilized to evaluate MRRMP alternatives at a programmatic level. *The Programmatic Agreement For The Operation And Management of the Missouri River Main Stem System For Compliance With The National Historic Preservation Act, As Amended, as well as The Programmatic Agreement Among The U.S. Army Corps Of Engineers, Kansas City District, U.S. Fish And Wildlife Service, Iowa Tribe Of Kansas And Nebraska, Osage Nation, Kansas State Historic Preservation Office, The Missouri State Historic Preservation Office, And The Advisory Council On Historic Preservation Regarding Implementation Of The Missouri River Recovery Management Plan In The Lower Missouri River From Rulo, Nebraska To The Confluence With The Mississippi River*, have been drafted to ensure that ongoing actions, and future projects tiered from this EIS, particularly those involving mechanical construction, are compliant with the National Historic Preservation Act, as amended and its implementing guidance 36 CFR 800.

Representative Quotes (Correspondence ID): 232
Comments (Comment ID): 645439

EC900 *Environmental Consequences: Cultural Resources*

Concern Statement: Alternatives that involve increasing flows have the potential to irrevocably harm significant cultural resources (i.e., archaeological sites) at the point of origin or in downstream settings. Increased flows that result in corresponding higher water surface elevations saturate cutbanks and promote conditions for long-term or permanent soil instability that often warrant extensive solutions to correct them. Fluctuating pool elevations dropping to low levels may offer limited or rare windows of opportunity for investigations to cultural resources. If other suitable habitats occur in off-channel settings then the potential conflict between competing management goals (biological vs. cultural) almost certainly would be drastically lessened or negated. Vegetation maintenance and mechanical construction ESH has the least potential to impact cultural resources in the overall scenarios as proposed.

Response: Noted. USACE is committed to open communication and consultation in regards to fostering conditions that have the least potential to impact cultural resources.

The preferred alternative does not include reoccurring flow actions with the potential to impact cultural resources. Site-specific coordination will occur for each construction project. *The Programmatic Agreement For The Operation And Management of the Missouri River Main Stem System For Compliance With The National Historic Preservation Act, As Amended, as well as The Programmatic Agreement Among The U.S. Army Corps Of Engineers, Kansas City District, U.S. Fish And Wildlife Service, Iowa Tribe Of Kansas And Nebraska, Osage Nation, Kansas State Historic Preservation Office, The Missouri State Historic Preservation Office, And The Advisory Council On Historic Preservation Regarding Implementation Of The Missouri River Recovery*

Management Plan In The Lower Missouri River From Rulo, Nebraska To The Confluence With The Mississippi River, have been drafted to ensure that ongoing actions for the preservation of critically endangered cultural resources on federally managed properties and future projects tiered from this EIS are compliant with the National Historic Preservation Act, as amended and its implementing guidance 36 CFR 800.

Representative Quotes (Correspondence ID): 239
Comments (Comment ID): 645407

Concern Statement: Based on information in the MRRMP-EIS management actions involving flows will negatively impact cultural resource protection. Early involvement of the State Historic Preservation Office and Historic Preservation Offices of the various Native American Tribes is encouraged during site selection for created sandbar locations.

Response: Noted. USACE is committed to open communication and consultation in regards to fostering conditions that have the least potential to impact cultural resources. The preferred alternative does not include reoccurring flow actions with the potential to impact cultural resources. Site-specific coordination will occur for each construction project. USACE recognizes the need for early involvement of federal, state, local, and Tribal partners to ensure preservation of cultural resources within the Missouri River system.

The Programmatic Agreement For The Operation And Management of the Missouri River Main Stem System For Compliance With The National Historic Preservation Act, As Amended, as well as The Programmatic Agreement Among The U.S. Army Corps Of Engineers, Kansas City District, U.S. Fish And Wildlife Service, Iowa Tribe Of Kansas And Nebraska, Osage Nation, Kansas State Historic Preservation Office, The Missouri State Historic Preservation Office, And The Advisory Council On Historic Preservation Regarding Implementation Of The Missouri River Recovery Management Plan In The Lower Missouri River From Rulo, Nebraska To The Confluence With The Mississippi River, have been drafted to ensure that future projects within the Missouri River system will be coordinated with federal, state, local, and Tribal partners, and comply with the National Historic Preservation Act, as amended and implementing guidance 36 CFR 800.

Representative Quotes (Correspondence ID): 206, 232
Comments (Comment ID): 645984, 645436

Concern Statement: The Draft MRRMP-EIS concludes that the Tribes are not impacted by current operations and the alternatives. However, USACE acknowledges that there are many unknown cultural resource sites existing on the landscape and the Final EIS Missouri River Master Water Control Manual Review and Update admits that its actions cause erosion and deterioration of Native American human remains and cultural objects.

Response: Potential impacts to Tribes from the alternatives and from past, present, and reasonably foreseeable actions are documented in Chapter 3 of the EIS. The preferred alternative does not include reoccurring flow actions with the potential to impact cultural resources. Site-specific coordination will occur for each construction project. USACE will continue to consult with SHPOs, Tribes and other interested parties on any proposed undertaking for the prevention, reduction, or mitigation of impacts to recorded and un-recorded cultural resources.

Representative Quotes (Correspondence ID): 232

Comments (Comment ID): 645472

Concern Statement: The Draft MRRMP-EIS lacks compliance with the National Historic Preservation Act and its implementing regulations and the findings are based on false or incomplete assumptions used in the determination of impacts to cultural resources.

Response: The existing cultural resource survey data were utilized to evaluate MRRMP alternatives at a programmatic level. The input and assumptions used in these evaluations were developed in consultation with states, Tribes, and cultural resources experts. The Programmatic Agreement For The Operation And Management of the Missouri River Main Stem System For Compliance With The National Historic Preservation Act, As Amended, as well as The Programmatic Agreement Among The U.S. Army Corps Of Engineers, Kansas City District, U.S. Fish And Wildlife Service, Iowa Tribe Of Kansas And Nebraska, Osage Nation, Kansas State Historic Preservation Office, The Missouri State Historic Preservation Office, And The Advisory Council On Historic Preservation Regarding Implementation Of The Missouri River Recovery Management Plan In The Lower Missouri River From Rulo, Nebraska To The Confluence With The Mississippi River, have been drafted to ensure that future projects within the Missouri river system will be coordinated with federal, state, local, and Tribal partners, and comply with the National Historic Preservation Act, as amended and implementing guidance 36 CFR 800.

Representative Quotes (Correspondence ID): 232
Comments (Comment ID): 645444

Concern Statement: The fluctuations in reservoir elevations contemplated in the Draft MRRMP-EIS will likely be more dramatic than the modeling suggests, resulting in greater impact to cultural resources especially impacting cultural resources at Oahe Reservoir. Additionally, the long-term forecast of diminished inflows and long-term drought in the central Great Plains caused by climate change will cause greater adverse impacts to cultural sites than forecast in the Draft MRRMP-EIS.

Response: A discussion of the influence of climate change to alternatives' operations is included in Section 3.2 River Infrastructure under Climate Change as well as Section 3.9 Cultural Resources under Climate Change, Section 3.9.2.10. Consultation and coordination with SHPOs, Tribes, and other interested parties will be conducted to manage potential impacts to this resource. Chapter 5 of the SAMP describes the process that will be followed regarding ongoing analysis of impacts to human considerations.

Representative Quotes (Correspondence ID): 232
Comments (Comment ID): 645443

Concern Statement: The Draft MRRMP-EIS mistakenly assumes that the environmental impacts of all alternatives will be equal in light of climate change. Each alternative will cause different levels of fluctuation.

Response: As noted in Section 3.9.2.10 Climate Change under the Cultural Resources section, potential impacts to cultural resources from climate change would follow from increases to variability of reservoir water surface elevations, and greater flow related damages in riverine settings. However, it is assumed that the variability and fluctuations from climate change would be similar under each alternative.

Representative Quotes (Correspondence ID): 232

Comments (Comment ID): 645442

Concern Statement: The use of the entire 82-year period of record to determine impacts on cultural resources ignores the effects of reservoir construction and will result in underestimating the actual impacts of water level fluctuations at the reservoirs.

Response: The alternatives considered under the Management Plan EIS including the “No Action” condition evaluates and compares impacts given the Mainstem reservoir system. The cumulative impacts section under Cultural Resources acknowledges that past, present, and reasonably foreseeable future actions have adversely affected cultural resources within the floodplain and Mainstem reservoir system.

Representative Quotes (Correspondence ID): 232
Comments (Comment ID): 645441

Concern Statement: The calculation of impacts to cultural resources from the alternatives in the Draft MRRMP-EIS is incorrect and the number of sites included in the model are based on outdated and incomplete cultural resource surveys.

Response: The analysis of impacts to cultural resource sites is based on existing available data in order to compare the relative impact to cultural resources across alternatives. It is understood that there are many unrecorded cultural resource sites existing on the landscape. The inventory of known cultural resource sites used in the analysis is intended to serve as a representative sample, indicating which Management Plan alternatives have greater or lesser impacts to cultural resources. A complete discussion of how the sites were selected and how data was obtained can be found in the “Cultural Resources Environmental Consequences Analysis Technical Report” available online (www.moriverrecovery.org).

Representative Quotes (Correspondence ID): 232
Comments (Comment ID): 645435

Concern Statement: Consider listing the order of the lakes in Table 3-27 from upstream to downstream.

Response: Noted. For clarity, the Mainstem lakes have been listed in order from upstream to downstream in the Final EIS.

Representative Quotes (Correspondence ID): 239
Comments (Comment ID): 645408

EC1000 *Environmental Consequences: Land Use and Ownership*

Concern Statement: It is recommended that the Land Use and Ownership section refer the reader to the Interior Drainage section for further details.

Response: The beginning of the land ownership section of the Final EIS (Section 3.10) refers the reader to the interior drainage and flood risk management section (Section 3.12 in the Final EIS), and irrigation section (Section 3.14 in the Final EIS) for further details on how the alternatives affect these agricultural activities.

Representative Quotes (Correspondence ID): 228
Comments (Comment ID): 645876

Concern Statement: The Land Use and Ownership section indicates that wildlife habitat is limited to “protected” acres and fails to mention that there are many acres of private lands on which conservation practices are implemented and habitat is provided; the Final EIS should remove language that refers to private lands as “unprotected” and indicate that private landowners are stewards of their lands.

Response: The terminology in the Land Ownership section in the Final EIS was (Section 3.10.1) changed to clarify that wildlife habitat is not only associated with federally owned acres, but also includes some private lands that provide wildlife habitat and private landowners are often stewards of their lands. The Final EIS Land Ownership Affected Environment section was also updated to note that the “protected” lands were defined with data from the “Protected Areas Database.” The Affected Environment section states, “Data from the Protected Areas Database of the United States (PAD-US), which is published by the USGS Gap Analysis Program, includes an inventory of federal and non-federal conservation and protected lands dedicated to the preservation of biological diversity and to other natural, recreational, and cultural uses.” According to Table 3-40 in Section 3.10.1, Land Use Affected Environment, these “protected” areas include other entities such as “non-governmental organizations or private land owners with conservation easements or other agreements that provide for protected land status.”

Representative Quotes (Correspondence ID): 228
Comments (Comment ID): 645847, 645496

Concern Statement: The Land Use and Ownership section need to assess more completely impacts to lands from interior drainage.

Response: The Final EIS includes a separate section on the impacts associated with flood risk management and interior drainage. Impacts associated with interior drainage to landowners is accounted for in the interior drainage section of the Final EIS (Section 3.12). The title of the land use and ownership section was changed to “Land Ownership” in the Final EIS. The Land Ownership section refers the reader to the flood risk management and interior drainage evaluations (Section 3.12), which provide details on flooding and high-water impacts on agricultural lands and crops. The Land Ownership evaluation is focused on the estimation of regional economic impacts from land acquisition if the land was previously in agricultural production, including reductions in farm jobs and income (and multiplier impacts) as well as reductions in property tax receipts to local governments.

Representative Quotes (Correspondence ID): 228
Comments (Comment ID): 645634

Concern Statement: Land acquisition for habitat creation will increase flood retention and improve water quality, which should be addressed in the Final EIS.

Response: The ecosystem services benefits associated with the acquisition of lands and the development of IRC and shallow water habitat, such as improved water quality and flood water retention, are evaluated in the ecosystem services section of the Final EIS (Section 3.23).

Representative Quotes (Correspondence ID): 242
Comments (Comment ID): 645578

Concern Statement: There are some inconsistencies in the targeted acres for acquisition presented in the Draft EIS (33,463 or 45,717). Please correct this error.

Response: The error was corrected in the Final EIS. The RED evaluation for Land Ownership focuses on the reduction in regional economic benefits (e.g., jobs and income) associated with the Federal acquisition of croplands. Because only a portion of the lands that would be acquired by the Federal government would be in croplands, only a portion of the acreage is used in the RED jobs and income evaluation (all federally acquired lands were used in the property tax evaluation). Section 3.10.2.1 presents the acreages used in the RED evaluation.

Representative Quotes (Correspondence ID): 228
Comments (Comment ID): 645548

Concern Statement: The Land Use and Ownership evaluation should clearly state that the RED impacts are overstated because of the incremental nature of the land acquisition.

Response: The Land Ownership section in the Final EIS (Section 3.12.2) states that the land acquisition and associated property tax impacts would be gradual and occur over the implementation period; this point was noted in the summary and under all of the alternatives (Section 3.12.2). The total impact at the end of the implementation period was the focus of the land ownership analysis.

Representative Quotes (Correspondence ID): 242
Comments (Comment ID): 645508

Concern Statement: Land use impacts occur with the rise and fall of river stages; more frequent and higher river stages cause greater economic impacts.

Response: The economic impact of changes in flood risk and interior drainage (e.g., agricultural and structural damages) due to changes in river stages and flows are addressed in the Final EIS, Section 3.12, Flood Risk Management and Interior Drainage.

Representative Quotes (Correspondence ID): 228
Comments (Comment ID): 645505

Concern Statement: The Land Use and Ownership evaluation is deficient for a number of reasons and understates the impacts to land use. The evaluation presents annual impacts of land acquisition, which creates a perception of smaller impacts than what is actually incurred (each year the impacts are incurred). Property tax losses are not the only impact to economic activity; farming activity contributes to federal individual and corporate taxes; and local sales tax, special use taxes, and personal property taxes. In addition, the Land Use and Ownership section should not be limited to land acquisition because any increase in river stages can affect land use (interior drainage) and many other issues (planting and harvesting, traffic, levees, infrastructure, navigation, dredging, power generation, water supply, water quality). There is a concern that USACE does not understand the subject matter or does not have the expertise to conduct the analysis.

The portion of the table devoted to Management Actions Common to All Alternatives (Table 3-42) says there are no RED impacts, no OSE impacts and no other impacts, and there is concern that increased flows under some of the alternatives would increase the risk of and the severity of flooding and impact interior drainage, which would affect land use. These impacts should be included in the table.

In addition, PILT payments are designed to offset the loss in tax revenues to local governments but these payments can vary from year to year and are capped at a maximum per acre payment.

Response: The Land Ownership evaluation estimates the regional economic impacts of land acquisition if the land was previously in agriculture, including reductions in farm jobs and income (and multiplier impacts) as well as reductions in property tax receipts to local governments. The analysis focuses on the reduction in property tax receipts at the end of the implementation period – that is, all lands would have been acquired. USACE agrees that the reduction in property taxes and jobs and income is a long-term impact that would occur each year, and this aspect has been added to the description in the Land Ownership Environmental Consequences section of the Final EIS (Section 3.10).

Additionally, estimates of PILT payments are included in the Land Ownership Environmental Consequences section of the Final EIS (Section 3.10.2). USACE agrees that federal acquisition of agricultural lands for habitat development would affect other fiscal receipts aside from property taxes. Because the land ownership would change from private to federal land, property tax receipts was a focus for the evaluation because property tax receipts to local governments would be directly affected. Other tax receipts such as corporate taxes, sales and use taxes, special use taxes, and payroll taxes could be affected as well, and the Land Ownership Environmental Consequences section (Section 3.10.2 of the Final EIS) was updated to describe these impacts. Changes in these tax receipts are anticipated to be small in relation to the estimated changes in property tax receipts, but could contribute additional adverse impacts to the reduction in local government receipts, especially in smaller rural counties. Although associated changes in other local, state, and federal tax receipts may be adverse, they would likely be small because the government payments to acquire the lands would be subject to taxes and support spending in the economy, offsetting some of the reductions in tax receipts and local government revenues.

The economic impact of changes in flood risk management and interior drainage are addressed in Section 3.12, Flood Risk Management and Interior Drainage. The flood risk management and interior drainage NED evaluation includes the damages to infrastructure and other physical property in the floodplain; flood emergency and other disaster relief costs; agricultural damages, including planting and harvesting costs. Please refer to Section 3.12.2.1 in the Final EIS for additional details on the flood risk management and interior drainage environmental consequences. Land use impacts in terms of agricultural impacts related to interior drainage, flood risk management, and irrigation are discussed in those respective sections to provide clarity on the impacts related to each resource area and to avoid double counting and/or possibly missing the estimation of benefits and losses. The Irrigation, Navigation, Commercial Sand and Gravel Dredging, Thermal Power, Hydropower, Water Supply, and Water Quality sections address impacts to those respective resources.

“Management actions common to all alternatives” do not include the flow releases because not all alternatives include flow releases. These “common to all” management actions include pallid sturgeon propagation and augmentation, vegetation management, and predator management.

Representative Quotes (Correspondence ID): 219, 228

Comments (Comment ID): 645501, 643498, 643500

Concern Statement: The Land Use and Ownership evaluation is deficient because the modeling is truncated and not scientific. The analysis omits important data and does not explain the cause and effect, starting from a baseline point. The synergistic effects of interrelated economic impacts are missing from the model (i.e., transportation and traffic,

water supply, navigation, etc.), causing the overall economic impacts of changes to land use and ownership for all alternatives to be understated.

Response: The Land Ownership section of the Final EIS (Section 3.10) evaluates the impact of the Federal acquisition of farming land for habitat, specifically the reductions in farming and multiplier jobs and income and property tax receipts associated with the change in ownership from private farmland to federal land for habitat. With regard to the comment on the baseline, the No Action Alternative includes Missouri River Recovery Program management actions because USACE currently manages the river to comply with the Biological Opinion. The No Action Alternative is used as a reference for comparison with the action alternatives. Specifically, the No Action alternative assumes the 20 acres per mile for early life stage habitat under the 2003 BiOp. USACE believes constructing habitat to meet existing acreage goals is a reasonable assumption for the No Action alternative. It is designed to estimate impacts in the future rather than impacts that have already been realized.

With regard to the comment on the assumptions for the human considerations evaluations, please refer to Section 3.12.2 in the Final EIS for a discussion of the analysis and assumptions associated with flood risk management and interior drainage; Section 3.15.2 for a discussion of the analysis and impacts to navigation; Section 3.18.2 for a discussion of the analysis and impacts to water supply; and Section 3.17.2 for a discussion of the analysis and impacts to thermal power. The assumptions for each of these evaluations are described in the associated environmental consequences methodology sections and further detailed in the associated technical reports. For example, the navigation NED evaluation estimates the loss in transportation rate savings, if navigation service levels change and/or if commodities must move off the river to overland modes of transportation. The Navigation Other Social Effects evaluation includes an estimate of the impacts to air emissions from a change in mode to truck and rail traffic under the alternatives as well as a description of the public health and safety associated with these transportation mode changes.

Regarding the comment about the synergistic impacts of the resources, other sections of the Final EIS address the impacts to flood risk, interior drainage, ecosystem services, water quality, water supply, hydropower, navigation, thermal power, and others as a result of the alternatives. The flood risk management and interior drainage NED evaluation includes the damages to agricultural damages, including planting and harvesting costs, infrastructure, and other physical property in the floodplain; flood emergency; and other disaster relief costs. Tables 2-30 and 2-31 provide consequence tables that show all impacts (beneficial and adverse) and an aggregation of the impacts, where possible, associated with the alternatives.

With regard to the hydrology and hydraulics and economic modeling, these models have been reviewed by: agency technical review; district quality control review; and independent external peer reviews. USACE believes that these approaches and model results provide sufficient information and analysis to compare across the alternatives.

Representative Quotes (Correspondence ID): 228
Comments (Comment ID): 645487

Concern Statement: USACE needs to consider local impacts and payments in lieu of taxes to offset the reductions in the tax base and fully analyze the impacts of land use and ownership implications in the Final EIS.

Response: The Land Ownership Environmental Consequences section of the Final EIS (Section 3.10) was updated to include estimates of PILT payments that will partially offset the reduction in property tax receipts to local governments. USACE agrees that federal acquisition of agricultural lands for habitat development would affect other fiscal receipts aside from property taxes. Because the land ownership would change from private to federal land, property tax receipts was a focus for the evaluation because property tax receipts to local governments would be directly affected. Other tax receipts such as corporate taxes, sales and use taxes, special use taxes, and payroll taxes could be affected as well, and the Land Ownership Environmental Consequences section (Section 3.10.2 of the Final EIS) was updated to qualitatively describe these impacts. Changes in these tax receipts are anticipated to be small in relation to the estimated changes in property tax receipts, but could contribute additional adverse impacts to the reduction in local government receipts, especially in smaller rural counties. Although associated changes in other local, state, and federal tax receipts may be adverse, they would likely be small because the government payments to acquire the lands would be subject to taxes and support spending in the economy, offsetting some of the reductions in tax receipts and local government revenues.

Representative Quotes (Correspondence ID): 131, 197, 221
Comments (Comment ID): 645292, 645285, 640151

Concern Statement: The impacts described in the Land Use and Ownership section are underestimated because the evaluation did not include indirect labor impacts.

Response: The Land Ownership evaluation (Section 3.10.2 in the Final EIS) uses the reduction in the value of crop production (associated with agricultural land being federal acquired for habitat) as the input into the IMPLAN Professional model. The direct, indirect, and induced impacts for jobs, income, and sales are estimated with the IMPLAN model. Direct, indirect, and induced income impacts are included in the total estimates in the tables in the Land Ownership Environmental Consequences section.

Representative Quotes (Correspondence ID): 197
Comments (Comment ID): 645286

Concern Statement: Landowners should be encouraged to voluntarily protect or enhance habitat for species protection. Habitat protection should only occur in areas where the conversion of the land for habitat is needed in the context of all of the habitat available. The impacts to land acquisition are understated in Section 3.10 of the Draft EIS. The economic activity generated by farming, impacts local sales tax, personal property tax, special use taxes, and these impacts are underestimated in the analysis.

Response: With regard to the comment on voluntary programs for habitat conservation, private property habitat incentive programs currently exist in the form of NRCS programs, such as the Conservation Reserve Program and the Wetlands Reserve Program, and some states also have similar programs. USFWS operates the Candidate Conservation program in partnership with state and federal agencies, Tribes, private organizations, and landowners, and the program works to reduce the threats to declining species and thus prevent the need for listing.

Many of these habitat incentive programs are identified and described in the cumulative actions (Section 3.1.3 of the Final EIS). Private property habitat incentive programs are not a part of this plan in part because of the unique in-river habitat types that are part of the alternatives (i.e., interception rearing habitat, emergent sandbar habitat).

The Land Ownership evaluation estimates the regional economic impacts of land acquisition if the land was previously in agriculture, including reductions in farm jobs and income (and multiplier impacts) as well as reductions in property tax receipts and PILT to local governments. The analysis focuses on the net reduction in local government revenue (reductions in property tax receipts less PILT) at the end of the implementation period – that is, when all lands would be acquired. USACE agrees that federal acquisition of agricultural lands for habitat development would affect other fiscal receipts aside from property taxes. Because the land ownership would change from private to federal land, property tax receipts to local governments was a focus of the evaluation. Other tax receipts such as corporate taxes, sales and use taxes, special use taxes, and payroll taxes could be affected as well, and the Land Ownership Environmental Consequences section was updated to qualitatively describe these impacts.

Representative Quotes (Correspondence ID): 219
Comments (Comment ID): 643498

Concern Statement: The Land Use and Ownership section should include the impacts of the land acquisition and habitat construction on the conversion of prime farmland to non-agricultural uses, as indicated under the Farmland Protection Policy Act. The habitat improvement activities have the potential to affect lands with NRCS easements in place.

Response: The Land Ownership Affected Environment section of the Final EIS (Section 3.10.1) was updated to include the percentages of prime farmland in the floodplain of the Missouri River. Because the exact location of the acquired lands is not known, the impacts associated with the conversion of prime farmland is uncertain. However, because of the prevalence of prime farmland in the floodplain of the Missouri River, there is the possibility that the Federal acquisition of private lands from willing sellers would result in a conversion of prime farmland to early life stage habitat for the pallid sturgeon, which has been described qualitatively in the Final EIS Section 3.10.2. Because farmland that is acquired is located within the floodplain, there can be impacts to agriculture from flooding and interior drainage, which can provide incentives for private landowners to sell their lands. Section 3.12 in the Final EIS provides the evaluation on flood risk management and interior drainage under the MRRMP-EIS.

With regard to MRRMP-EIS management actions affecting lands with NRCS easements in place, USACE understands that there are various federal, state, and local property interests along the Missouri River and will work with these agencies to ensure that the USACE land acquisition and other management actions under the MRRMP will not adversely affect agency missions and objectives. The Final EIS has been updated to describe these intentions with regard to USACE land acquisition and management.

Comments (Comment ID): 642147, 641525

Concern Statement: Increased floodplain connectivity and removing farmland from production would have a large economic effect on the state of North Dakota. The Land Use and Ownership section only evaluates the impacts to property tax, and there are more issues that need to be addressed. Farmers need to retain the lands to better manage them to provide a balanced ecosystem.

Response: The Land Ownership section of the Final EIS (Section 3.10) evaluates the impact of the federal acquisition of farming land for habitat, specifically the reductions in farming and multiplier jobs and income and property tax receipts associated with the change in

ownership from private farmland to federal land for habitat. The IMPLAN model is used to estimate the direct, indirect, and induced jobs, income, and sales associated with the decreased crop production. The state of North Dakota would not be affected by federal purchases of lands for interception rearing habitat and shallow water habitat because lands would only be acquired from willing sellers and acquisition of lands would only occur in the lower river from roughly Sioux City to St. Louis. Other sections in the Final EIS evaluate the impacts to agriculture from flooding and irrigation. Please see Sections 3.12 (Flood Risk Management and Interior Drainage) and 3.14 (Irrigation) for additional details.

USACE agrees that federal acquisition of agricultural lands for habitat development would affect other fiscal receipts aside from property taxes. Because the land ownership would change from private to federal land, property tax receipts was a focus for the evaluation because property tax receipts to local governments would be directly affected. Other tax receipts such as corporate taxes, sales and use taxes, special use taxes, and payroll taxes could be affected as well, and the Land Ownership Environmental Consequences section (Section 3.10.2 of the Final EIS) was updated to qualitatively describe these impacts.

Representative Quotes (Correspondence ID): 96
Comments (Comment ID): 640292

Concern Statement: USACE has not included an evaluation of whether federally acquired lands have increased the value of neighboring lands or properties.

Response: The Land Ownership section of the Final EIS evaluates the impact of the federal acquisition of farming land for habitat, specifically the reductions in farming and multiplier jobs and income and property tax receipts associated with the change in ownership from private farmland to federal land for habitat. The IMPLAN model is used to estimate the direct, indirect, and induced jobs, income, and sales associated with the decreased crop production. The changes in ecosystem services associated with the MRRMP-EIS alternatives are provided in Section 3.23 of the Final EIS, Ecosystem Services. The Final EIS has been updated to describe many ecosystem services associated with the acquisition of land, the development of habitat, and other MRRMP-EIS management actions. A qualitative description of the potential increased value of neighboring lands associated with adjacent Federal lands has been added to Section 2.23; these benefits were not monetized because of the uncertainty of the location of the land acquisition, the vast geographic scale, the many factors affecting the value of the property, and considerable data needed for such an evaluation.

Representative Quotes (Correspondence ID): 131
Comments (Comment ID): 640152

Concern Statement: The Land Use and Ownership section should note that if lands that are acquired by the federal government are prone to production issues, such as flooding, then there would be a smaller adverse impact on the tax base and the regional economic impacts of crop production. In addition, federal acquisition of these lands would also reduce federal payments for flood insurance.

Response: USACE agrees and understands that agricultural land owners that have repeated crop production issues due to flooding and interior drainage are more likely to willingly sell their lands to USACE. In addition, marginally crop-producing lands would also be relatively lower-valued agricultural lands. These aspects were added and qualitatively

described in the Final EIS, including the potential for changes to the tax base and jobs and income. In addition, the Section 3.10.2 also explains that lands that are federally acquired would no longer be susceptible to flood risk and potential payments for crop damage from flooding.

Comments (Comment ID): 640151, 640148, 644934

Concern Statement: USACE should work with adjacent landowners who would be affected by IRC habitat development.

Response: The siting of habitat areas considers protective measures around sensitive infrastructure and facilities, such as water supply intakes and thermal power plants. USACE works closely with nearby land and facility owners to minimize impacts and would conduct site-specific NEPA analyses prior to constructing the habitat.

AE1100 *Affected Environment: Commercial Sand and Gravel Dredging*

Concern Statement: There appears to be an error with the statement “the primary area served by existing dredging operations is generally 2,050 miles from the sand plants.”

Response: The sentence in Section 3.11.1.2 line 18 should read, “...generally 20 to 50 miles...” This was corrected in the Final EIS.

Representative Quotes (Correspondence ID): 239
Comments (Comment ID): 645409

EC1100 *Environmental Consequences: Commercial Sand and Gravel Dredging*

Concern Statement: The Draft EIS fails to acknowledge that the HEC-RAS model is inappropriate for any permitting related decisions focused on commercial sand dredging. The analysis should consider how IRC construction would impact channel response, impacts to navigation, bend hydraulic conditions; all of which would have indirect impacts on commercial sand dredging. USACE should consider the impact of the alternatives on sovereign rights of states (Missouri, Kansas, Iowa, and Nebraska) who own the bed of the lower river.

Response: Section 404 and Section 408 regulatory processes are not part of the MRRMP-EIS process; however, the Final EIS estimates the potential impacts from future protective measures that may be necessary in the vicinity of Interception Rearing Complex (IRC) projects (Section 3.11 of the Final EIS). This analysis does not create a restriction; however, it does project what impacts could be in the future if restrictions result from the Regulatory process.

HEC-RAS is designed to perform one-dimensional hydraulic calculations for a full network of natural and constructed channels. The purpose of the HEC-RAS models was to create a baseline that closely represents current river conditions and to provide a tool to evaluate potential hydraulic changes resulting from proposed management actions or alternatives (e.g., channel reconfiguration and/or flow management). HEC-RAS is used extensively throughout the world and is an appropriate model for this EIS. In addition to the HEC-RAS analyses referenced above, a separate, high-level analysis was

conducted to assess the impact that changing flow releases in accordance with the alternatives could have on sediment accumulation rates in the dredging segments. While this analysis utilized the flow routing capability of the HEC-RAS model to determine flows for the various alternatives, the evaluation was a gage analysis based on rating curves rather than a modeling exercise. It used the change in sedimentation rates from seven USGS gages located at different points between St. Joseph and Hermann, Missouri as the basis for the impact assessment. The technical basis and limitations for this analysis is further described in the supporting document “Commercial Sand and Gravel Dredging Environmental Consequences Analysis Technical Report,” which is available online (www.moriverrecovery.org).

IRCs would be highly localized features for the interception, food-producing, and foraging habitats for age-0 pallid sturgeon, as well as for the retention of young fish in supportive habitats. Similar to past regulatory permit evaluations, USACE Regulatory Branch will consider the potential impacts of permitted activities on any ESA listed species. Past permitting actions have identified Pallid Sturgeon Resource Protection Zones based upon the best available scientific information at that time. During future permitting processes, protective measures may be added or deleted based upon new information, the need for resource protection at specific sites, and the geographic locations where the permitted activity is being evaluated. A general description of protective measures proposed by the MRRP has been added to Chapter 2 and a discussion of the potential impacts to commercial sand and gravel dredging associated with these protective zones has been added in Chapter 3. Additional site-specific analysis (NEPA) will be conducted once these locations are identified and prior to construction.

USACE understands and recognizes states’ sovereign rights, and is committed to working with the states on site-specific projects. However, projects impacting the bed are generally constructed in the navigation servitude. The navigation servitude is the dominant right of the Government under the Commerce Clause of the U.S. Constitution to use, control, and regulate the navigable waters of the United States and submerged lands thereunder for various commerce-related purposes, including navigation and flood control. The navigation servitude extends from the Ordinary High Water Mark to Ordinary High Water Mark.

Representative Quotes (Correspondence ID): 187, 228
Comments (Comment ID): 641557, 645512

Concern Statement: The Pick-Sloan Act included recommendations for the expected width of the channel and the width that should be established between the federal and non-federal levees. Neither of these guidelines were ever followed and the result is too narrow of a channel and levees too close to the river.

Response: The MRRMP-EIS describes the existing navigation channel and structures and the impacts of the alternatives in Section 3.15. Existing flood risk management and interior drainage infrastructure and the impacts of the alternatives are addressed in Section 3.12. Changes to the authorized navigation channel and flood risk management infrastructure are not part of the proposed action and are therefore outside the scope of this EIS.

IRCs would be highly localized features for the interception, food-producing, and foraging habitats for age-0 pallid sturgeon, as well as for the retention of young fish in supportive habitats. Similar to past regulatory permit evaluations, USACE Regulatory

Branch will consider the potential impacts of permitted activities on any ESA listed species. Past permitting actions have identified Pallid Resource Protection Zones based upon the best available scientific information at that time. During future permitting processes, Pallid Resource Protection Zones may be added or deleted based upon new information, the need for resource protection at specific sites, and the geographic locations where the permitted activity is being evaluated. A general description of IRC protective zones proposed by the MRRP has been added to Chapter 2 and a discussion of the potential impacts to commercial sand and gravel dredging associated with these protective zones has been added in Chapter 3. Additional site-specific analysis (NEPA) will be conducted once these locations are identified and prior to construction.

While USACE understands and recognizes states sovereign rights, the power of the United States over its waters which are capable of use as interstate highways arises from the “Commerce Clause” of the Constitution, Article 1, Section 8, Clause 3. The Missouri River is recognized as a navigable stream. The Federal Government has an inherent easement in navigable water up to the mean high water, in the exercise of which it may erect works for navigation which impair the interests of the owner of the upland, without incurring Fifth Amendment liability.

Comments (Comment ID): 641557, 645512

Concern Statement: For the Final EIS, USACE should evaluate the impacts of flow changes on sand and gravel operations.

Response: HEC-RAS is designed to perform one-dimensional hydraulic calculations for a full network of natural and constructed channels. The purpose of the HEC-RAS models was to create a baseline that represents current river conditions and to provide a tool to evaluate potential hydraulic changes resulting from proposed management actions or alternatives (e.g., channel reconfiguration and/or flow management). HEC-RAS is used extensively throughout the world and is an appropriate model for this EIS. In addition to the HEC-RAS analyses referenced above, a separate, high-level analysis was conducted to assess the impact that changing flow releases in accordance with the alternatives could have on sediment accumulation rates in the dredging segments. While this analysis utilized the flow routing capability of the HEC-RAS model to determine flows for the various alternatives, the evaluation was a gage analysis based on rating curves rather than a modeling exercise. It used the change in sedimentation rates from seven USGS gages located at different points between St. Joseph and Hermann, Missouri as the basis for the impact assessment. The technical basis and limitations for this analysis is further described in the supporting document “Commercial Sand and Gravel Dredging Environmental Consequences Analysis Technical Report,” which is available online (www.moriverrecovery.org). The sand and gravel dredging evaluation in the navigation section (Final EIS Section 3.15, Navigation) focuses on the impacts associated with the transportation of commercial sand and gravel for each of the alternatives; that is how high and low flow conditions affect the ability of the dredgers to extract and transport the material to their sand plants.

Representative Quotes (Correspondence ID): 197
Comments (Comment ID): 645281

Concern Statement: There are differences in results in the Navigation and Commercial Sand and Gravel Dredging sections for Alternatives 4–6.

Response: The Commercial Sand and Gravel Dredging Section (3.11) evaluates the impacts on the availability of sand and gravel material from changes in the sedimentation accumulation rate under each of the MRRMP-EIS alternatives. The sand and gravel dredging evaluation in the navigation section (Final EIS Section 3.15, Navigation) focuses on the impacts associated with the transportation of commercial sand and gravel for each of the alternatives because high and low flow conditions affect the ability of the dredgers to extract and transport the material to their sand plants. Additional details are described in the “Commercial Sand and Gravel Dredging Environmental Consequences Analysis Technical Report” and “Navigation Environmental Consequences Analysis Technical Report” available online (www.moriverrecovery.org). The availability of material (sediment accumulation rate) would result in negligible changes in sediment accumulation across the alternatives. The navigation sand and gravel dredging evaluation shows that there would be negligible changes compared to No Action in river flows and stages affecting the ability to dredge and transport commercial sand and gravel under Alternatives 2, 3, and 5, and negligible to small adverse impacts under Alternative 4 and 6 from additional days below low flow thresholds. Because the analyses examined different aspects of sand and gravel dredging, it is expected that the results may differ.

Representative Quotes (Correspondence ID): 240
Comments (Comment ID): 644965

Concern Statement: The Draft MRRMP-EIS overstates the impacts to sand and gravel dredging under the topic of navigation as well as under its own category, particularly since the conclusions of the MRRMP-EIS in the Commercial Sand and Gravel Dredging section conflict with the conclusions in the Navigation section. Sand and gravel dredging is not a congressionally authorized use of the Missouri River and should afford no special protection in the development of alternatives. If anything, reducing dredging activity would seem to accrue benefits to species protection.

Response: Commercial sand and gravel dredging was evaluated as part of the Affected Environment because it is an activity that currently exists on the river and has been identified by stakeholders as an important human consideration associated with the Missouri River. The analysis of impacts includes a wide range of Missouri River interests and is not limited to the congressionally authorized purposes. The statement regarding the authorized purposes in Section 2.5.3.1 has been updated to clarify that commercial sand and gravel dredging is not one of the authorized purposes.

The Commercial Sand and Gravel Dredging Section (3.11) evaluates the impacts to the availability of sand and gravel material from changes in the sedimentation accumulation rate for each of the alternatives. The navigation analysis evaluates the impacts associated with how changes in river flows and stages affect the ability to dredge and transport commercial sand and gravel. Because the analyses examined different aspects of sand and gravel dredging, it is expected that the results may differ.

USACE does not consider the impacts to sand and gravel dredging to be overstated. In Section 3.11.2.3 of the Commercial Sand and Gravel analysis, Table 3.51 states under “Summary of Impacts” that there is a negligible change in the sediment accumulation rate under each of the alternatives, thus a negligible impact to the commercial sand and gravel industry with regard to sediment availability. The navigation section evaluates the impacts to the ability to dredge and transport commercial sand and gravel. Additional details are described in the “Commercial Sand and Gravel Dredging Environmental

Consequences Analysis Technical Report” and “Navigation Environmental Consequences Analysis Technical Report” available online (www.moriverrecovery.org).

AE1200 *Affected Environment: Flood Risk Management and Interior Drainage*

Concern Statement: The Affected Environment section for Flood Risk Management and Interior Drainage should include surveyed data on approximately 1,400 individual interior drainage structures located along the Missouri River.

Response: In addition to the detailed assessment conducted on four representative interior drainage sites, the Final EIS includes an updated proxy analysis that incorporates survey data from over 100 interior drainage structures. This analysis provides an indication of the potential risk to interior drainage structures as a result of the alternatives and is sufficient for estimating the relative impacts of the different alternatives.

Representative Quotes (Correspondence ID): 36

Comments (Comment ID): 628350

Concern Statement: It has been reported that floodwater levels are increasing and rising along areas that have been channelized. Flood levels have increased from 1.2 to 1.9 meters.

Response: HEC-RAS model geometry is based on the best available topographic surveys. All constructed models were calibrated to the same period through 2012. Model calibration is discussed in the supporting documents, HEC-RAS Calibration Report, which is available online (www.moriverrecovery.org).

The Missouri River is a dynamic system that is changing constantly over the study area, which extends from Fort Peck dam downstream to the Missouri River mouth at St. Louis. Some areas have experienced continued degradation since 2012 while other areas have experienced aggradation. All alternatives were modeled with HEC-RAS using the same geometry and the comparison between the alternatives is valid. While trends maybe occurring at variable levels within the expansive study area, the attempt to include study trends is not relevant for alternative comparison.

An assessment of potential climate change effects on the various resources was included in the Draft EIS within subsections of each applicable resource (e.g., Section 3.2.2.7). A basin wide evaluation is described in the supporting document Climate Change Assessment – Missouri River Basin which is available online (www.moriverrecovery.org).

Representative Quotes (Correspondence ID): 68

Comments (Comment ID): 633532

Concern Statement: What is the economic impact of the alternatives as it relates to flood risk?

Response: A detailed description of the flood risk management analysis and results from the impacts of the Final EIS alternatives can be found in the “Flood Risk Management Environmental Consequences Analysis Technical Report.”

Representative Quotes (Correspondence ID): 127

Comments (Comment ID): 636922

Concern Statement: At higher river stages (2 to 4 feet below flood stages), interior drainage districts (L575) start to experience impacts.

Response: USACE acknowledges interior drainage impacts can begin before flood stages are reached. The Final EIS includes an updated proxy analysis that incorporates the survey data from the individual interior drainage structures.

Representative Quotes (Correspondence ID): 135, 175
Comments (Comment ID): 637265, 641397

Concern Statement: The Pick-Sloan Act included recommendations for the expected width of the channel and the width that should be established between the federal and non-federal levees. Neither of these guidelines were ever followed and the result is too narrow of a channel and levees too close to the river.

Response: Comment noted. This concern is in reference to past authorizations and construction actions and is not within the scope of the MRRMP-EIS.

Representative Quotes (Correspondence ID): 179
Comments (Comment ID): 645236

Concern Statement: The agencies should use the term "flood control" instead of "flood risk management."

Response: The term "flood control" is used when referring to the authorized purposes and the Flood Control Act of 1944. However, in 2008, the Army proposed an update to "flood risk management" to be used agency-wide in briefings, newsletters, and press releases, as well as in budget, management, and policy documents. This update emphasizes the broader risk management activities of USACE to ensure competency in risk assessment and to communicate to the public the nature of flood risks and how they can be managed.

Representative Quotes (Correspondence ID): 221
Comments (Comment ID): 645293

Concern Statement: The Draft EIS fails to mention that the greatest impact from flooding is the delay or prevention of agricultural activity.

Response: USACE acknowledges impacts from flooding include the delay or prevention of agricultural activity. The costs of delayed or prevention of agricultural activity are incorporated in the Flood Impact Analysis model. Please refer to Flood Risk Management and Interior Drainage Environmental Consequences Sections 3.12.3 and 3.12.4 and the associated technical reports for a discussion of the factors affecting delayed or prevented agricultural activity.

Representative Quotes (Correspondence ID): 228
Comments (Comment ID): 645534

EC1200 *Environmental Consequences: Flood Risk Management and Interior Drainage*

Concern Statement: The "Flood Risk Management Environmental Consequences Analysis Technical Report" provides little detail on the actual modeling that was conducted for this resource topic. The discussion in the technical report is basically a rehash of the

information that was included in the Draft EIS. The technical document does not allow reviewers to understand the approach and either agree or disagree with the results.

Response: USACE has remained transparent throughout this process and believes the description in the technical reports are an accurate description of the methods that were used. Further technical details on the flood risk management approach and modeling have been added to the “Flood Risk Management Environmental Consequences Analysis Technical Report.”

Representative Quotes (Correspondence ID): 1
Comments (Comment ID): 645666

Concern Statement: The definition of significance needs to be revisited in the discussion of impacts in the Flood Risk Management section. In some places (e.g., Alternative 4), the author seems to discount an increase in over 2,000 individuals impacted, especially in rural areas.

Response: USACE has updated the discussion on significance to provide further clarity as it relates to the flood risk management impacts. The population at risk discussion in Section 3.12.3 has also been updated to distinguish impacts by location and to clarify the impacts and significance of results.

Representative Quotes (Correspondence ID): 1
Comments (Comment ID): 645677

Concern Statement: Any increase in flood constraints under any of the alternatives could result in the reduction and/or elimination of thousands of acres of agriculture lands and increase risks to public health and safety. The river changes greatly and sudden storm events in very short periods of time combined with a spring pulse event could lead to increased flooding in communities and agricultural areas.

Response: USACE acknowledges that changes to the length or intensity of a flow event has the ability to affect flood constraints and impacts. The current hydrology, hydraulics, and economic analyses evaluate the impacts associated with alternatives including impacts associated with changes in reservoir releases. Additional hydrology, hydraulic and economic analyses would be conducted if adaptive management identifies the need for future flow measures.

Representative Quotes (Correspondence ID): 1
Comments (Comment ID): 626071

Concern Statement: Alternatives 4 and 5 have the potential to impede interior drainage and increase flooding which can harm crop production during the worst time of year.

Response: USACE acknowledges that the timing of pulse events in Alternatives 4 and 5 could adversely impact agriculture. A discussion of the potential flooding impacts resulting from Alternatives 4 and 5 is presented in Section 3.12.2.7 and 3.12.2.8 of the EIS, respectively. However, these two alternatives were not identified as preferred alternatives.

Representative Quotes (Correspondence ID): 228
Comments (Comment ID): 645451

Concern Statement: The Draft EIS included an abbreviated analysis for interior drainage for all alternatives. This analysis requires substantial recalibration because the economic

conclusions are inaccurate and incomplete due to the failure to provide robust and accurate modeling and impact data on interior drainage. The impact on land use-impaired interior drainage was not thought to be enough of a priority to perform modeling and impacts analyzed. Interior drainage impacts should be thoroughly analyzed using the 2005 interior drainage data, or similar data, in the Final EIS for a proper analysis of the impacts. A RED analysis should be conducted to determine the full impacts of alternatives on interior drainage.

Response: Because the models are quite complex and time consuming to develop, it was not feasible to model every levee on the Missouri River. Therefore, a sub-set of the sites evaluated for the Master Manual (USACE, 1998) were selected to be modeled in detail. Extrapolation of the results of these sites to other drainage sites is not recommended since the hydrology, hydraulics and drainage varies at each interior drainage site.

USACE also understands the concerns related to inclusion of other drainage sites. Therefore, USACE has incorporated additional data, analysis, and results of impacts to interior drainage in Section 3.12.3 in the Final EIS based on surveyed data of over 100 additional interior drainage sites. This analysis compared the frequency of stages exceeding flap gate elevations over the period of record for each alternative to provide an indication of impacts to interior drainage sites from the alternatives.

In addition, the dollar value results for the modeled sites on a per acre basis have also been included with the results discussion in Section 3.12.3 for further understanding of impacts to interior drainage sites on a per acre basis.

With regard to the interior drainage RED evaluation, the NED results were further evaluated to determine if regional economic conditions would be affected under the MRRMP-EIS alternatives. For all MRRMP-EIS alternatives, the largest increase in average annual agricultural damages from Alternative 1 was under Alternative 6 of \$7,800 (MRLS-536L), which would result in negligible changes in RED effects on the average compared to Alternative 1. The largest adverse difference in all years for agricultural damages would occur under Alternative 4 and 5 with the largest increase in damages of \$434,000 (Missouri River Levee System (MRLS-536L), which would result in a loss of up to 4 average annual agricultural jobs. Because all agricultural losses in any year would result in less than 4 jobs, a full RED analysis was not undertaken on the interior drainage impacts.

Representative Quotes (Correspondence ID): 228
Comments (Comment ID): 645780

Concern Statement: The discussion of impacts seems to discount the magnitude of impacts that would occur from increased flooding.

Response: The Regional Economic Development section provides an evaluation of the jobs, income, and sales that would be affected by agricultural damages from flooding. Each reach is evaluated, and the average of the 8-worst difference year damages and 8-best damage years relative to Alternative 1 and 8-best years relative to Alternative 1 were also provided in Section 4 of the "Flood Risk Management Environmental Consequences Analysis Technical Report." There are some reaches that would be affected in the average of the 8 worst difference years (up to a reduction in 13 jobs in the Gavins Point Dam to Rulo reach), but there are more years with reduced damages that would offset these adverse impacts resulting in very little change in RED effects on average associated with agricultural damages. Section 4.1 of the "Flood Risk Management Environmental Consequences Analysis Technical Report" also provides

the average annual structural damages for all of the counties along the Missouri River, by state.

Representative Quotes (Correspondence ID): 228
Comments (Comment ID): 645633

Concern Statement: A RED analysis needs to be conducted for flood risk management along the Mississippi River.

Response: A detailed RED assessment of impacts on the Mississippi River was not conducted because there were minimal average annual NED agricultural damages (ranging from 0.3 to 0.7 percent) and structural damages (ranging from 0.3 to 1.3 percent) across all alternatives compared to No Action. Changes in average annual NED damages would range from \$33,000 to \$161,000.

Representative Quotes (Correspondence ID): 228
Comments (Comment ID): 645618

Concern Statement: The SAMP indicates constructed IRC habitat can decrease stages for most flows. The Flood Risk Management section in the Draft EIS should further evaluate the impact of IRC habitat construction on flood risk management. The changes in flood risk associated with mechanical ESH construction should also be evaluated.

Response: IRC habitat construction may locally decrease the stage slightly due to added conveyance; however, IRC effects on river flow levels is regarded as incidental. IRC habitat project formulation was not intended to provide flood risk management.

IRCs would be designed to create effective interception hydraulics, food producing, and foraging habitats on the Lower Missouri River. For these projects to be effective and sustainable, the IRC projects would be designed such that the navigation channel and overall bed and hydrological conditions would largely remain unaffected. Refer to the supporting technical documents for a thorough description of modeling methodology, assumptions, and limitations.

ESHs are built using sand from the adjacent area. Restrictive criteria are employed in ESH design to avoid river impacts. Specifically, a small amount of sand is typically added onto an existing bar that is slightly below the water surface from the adjacent river area. ESHs are designed to balance conveyance within the same river section to avoid a net impact on flow area within that section.

Representative Quotes (Correspondence ID): 239, 242
Comments (Comment ID): 645587, 641841

Concern Statement: While lands acquired for habitat could reduce the amount of agricultural land that could be affected by flooding, a change in the land use and management may have implications for the regional economy, as well as, other resources on the river.

Response: USACE has updated the EIS to further explain the assumptions and methodology used for the analysis. While it is noted that lands acquired for habitat that were previously in agricultural production could reduce the amount of agricultural land that could be affected by flooding, it is also acknowledged that a change in the land use and management may have implications for the regional economy. The Land Ownership section of the Final EIS (Section 3.10) evaluates the impact of the federal acquisition of agricultural land for habitat, specifically the reductions in farm jobs and income (and

multiplier impacts) and property tax receipts associated with the change in ownership from private farmland to federal land for habitat. The IMPLAN model is used to estimate the direct, indirect, and induced jobs, income, and sales associated with the decreased crop production. Federal purchases of lands for habitat would only be acquired from willing sellers.

The Navigation, Commercial Sand and Gravel Dredging, Thermal Power, Hydropower, Water Supply, and Water Quality sections address impacts to those respective resources from each of the alternatives.

Representative Quotes (Correspondence ID): 228
Comments (Comment ID): 645549

Concern Statement: The RED section indicates that all flooding is due to natural hydrologic cycles and fails to mention the flood control capabilities of the reservoir system.

Response: The Missouri River system as currently operated provides substantial flood risk management to the entire basin as described in Section 3.12. In Section 3.12.3, it is noted that relatively high water or flooding years, such as those that occurred with conditions similar to 1951, 1984, 1986, 1993, and 2011, would account for the largest economic impacts from agricultural losses, and that these flooding effects are a result of the natural hydrologic cycles of precipitation and snow pack and not from the management actions under No Action. This section is not stating that damages are solely from natural events but noting that the natural hydrologic cycles of precipitation and snow pack are associated with the largest economic losses to agriculture. This statement will be clarified in the Final EIS to note that the management actions of habitat creation and the plenary pulse would not contribute to these flooding damages because the plenary pulse does not occur in any of the years noted above.

The Regional Economic Development section provides an evaluation of the jobs, income, and sales that would be affected by agricultural damages from flooding. Each reach is evaluated, and the average of the 8-worst damage years relative to Alternative 1 and 8-best years relative to Alternative 1 were also provided in Section 4 of the “Flood Risk Management Environmental Consequences Analysis Technical Report.” There are some reaches that would be affected in the average of the 8 worst difference years (up to a reduction in 13 jobs in the Gavins Point Dam to Rulo reach), but there are more years with reduced damages that would offset these adverse impacts resulting in very little change in RED effects on average associated with agricultural damages. Section 4.1 of the “Flood Risk Management Environmental Consequences Analysis Technical Report” also provides the average annual structural damages for all of the counties along the Missouri River, by state.

Representative Quotes (Correspondence ID): 228
Comments (Comment ID): 645545

Concern Statement: The analysis of Alternative 1 indicates that flood damage is caused by runoff events that occur downstream from the reservoir system, large upstream runoff events resulting from evacuation of flood water from reservoirs or a combination of the two but not from management actions under Alternative 1. The analysis does not account for flooding that would occur with the implementation of the bimodal Spring Pulse that could occur under Alternative 1.

Response: For purposes of modeling the No Action alternative, USACE assumed continued implementation of the plenary spring pulse as described in the Master Manual. The

impacts associated with this No Action condition is included in the flood risk management assessment.

The following text has been inserted within the EIS, Section 3.12.2.1, Impacts Assessment Methodology:

The Missouri River system as currently operated provides substantial flood damage reduction and benefits to the entire basin. Study alternatives include modifying operations of the Missouri River reservoir system with both higher and lower reservoir releases during select periods for species habitat benefits. The current HEC-ResSim and HEC-RAS analysis shows the potential for negative impacts to flood damage reduction for alternatives that include changes in reservoir flow releases. The current study methodology, which employs an 82-year period of record, is suitable for alternative comparison and providing an indication of change in flood risk. However, the methodology does not simulate a sufficient number of events and possible runoff combinations within the large Missouri River basin to evaluate potential change in downstream flood risk. Prior to implementing any management action that alters reservoir operations, a comprehensive flood risk evaluation will be conducted per USACE requirements. The level of additional hydrologic analysis will be based on USACE guidance and requirements and will identify the change in reservoir pool probability, reservoir release frequency, river stage-frequency, and river stage-duration.

Comments (Comment ID): 645542

Concern Statement: Each of the six alternatives include a flow regimen though the tables that show management actions common to all alternatives fail to show NED, RED or OSE impacts from these flows. This includes impacts to agriculture production and land values. The table also claims that Alternative 2 has lower flood risks than Alternative 1 which is difficult to understand. How higher artificial flows during the rainy spring season create lower flood risk is counterintuitive and illogical. The table claims Alternative 4 modeling resulted in a -\$21 million to \$48 million impact to NED. Given the large range in impacts under Alternative 4 the model may need to be recalibrated or Alternative 4 needs to be broken into two alternatives to reflect impacts more accurately. Any management action that deliberately floods any portion of the basin should be deemed unacceptable and be eliminated from the list of alternative actions.

Response: To clarify, management actions “common to all alternatives” do not include the flow releases because not all alternatives include flow releases. These “common to all” management actions include pallid sturgeon propagation and augmentation, vegetation management, and predator management. The Management Actions Common to All Alternatives section has been updated to better illustrate the impacts shown in Table 3-31, Environmental Consequences Relative to Flood Risk Management Changes. The range of impacts from -\$21 million to \$48 million for Alternative 4 represents the annual maximum and minimum over the POR and demonstrates the variation in flow events over the period of record. USACE also acknowledges the questions and concerns regarding the flood risk results for the alternatives and has updated the EIS to further explain the approach, methodology, and results for the flood risk management and interior drainage analysis.

Comments (Comment ID): 645539

Concern Statement: There was no inclusion of costs for rehabilitation of land, pumping costs, drainage infrastructure, repair to private levees or future yield losses due to damages to the land (sand and driftwood deposits, additional weed pressure, extra tillage requirements, etc.) included in the flood risk management RED analysis.

Response: The RED evaluation focused on the adverse regional economic impacts from flooding on agricultural and structural damages. Expenditures in the regional economy on levee repair, land rehabilitation, pumping costs, etc., generally provide increases in RED benefits, and therefore were not included in the evaluation.

However, the NED evaluation includes tangible damages to businesses, homes, and other physical property items caused by flood inundation or exposure as well as the costs of flooding such as emergency costs and disaster relief costs. Emergency cost savings encompass savings related to a wide range of flooding impacts, including emergency personnel costs, flood fighting costs (sandbagging, for example), avoidance costs (raising or evacuation of property), temporary food and housing, debris cleanup, and damage to infrastructure items not otherwise included in the damage analysis such as sewer lines. These types of impacts are further discussed in Section 2.4.3 of the "Flood Risk Management Environmental Consequences Analysis Technical Report."

Representative Quotes (Correspondence ID): 228
Comments (Comment ID): 645536

Concern Statement: It should be stated that the flood risk management model does not account for the effects of ice and therefore likely underestimates the frequency of exceeding channel capacity.

Response: A footnote has been added to Table 3-65. Frequency of Releases Simulated to Equal or Exceed Channel Capacity *

* All tabulated values are for open water conditions without any ice, debris, or other effects that can significantly affect river stages.

Comments (Comment ID): 645412

Concern Statement: USACE should make it clear if "floodplain" is referring to those areas that are determined by FEMA National Flood Insurance Program studies or if they are defining it using other methods.

Response: For the purposes of modeling impacts to flood risk management, USACE defined the floodplain as bluff-to-bluff with a buffer to account for uncertainties in the model. This is not the same as FEMA National Flood Insurance Program studies, but is likely similar. This clarification has added to the Final EIS.

Representative Quotes (Correspondence ID): 239
Comments (Comment ID): 645411

Concern Statement: The U.S. Supreme Court held that recurrent flooding, even if each flood was finite in duration, was not categorically exempt from Takings Clause liability, and that takings temporary in duration could be compensable. USACE must assume liability for damages caused to private lands and crops from any changes in flood control structures.

Response: USACE has considered the potential impacts from the alternatives and will comply with all laws, statutes, and case law when implementing the MRRMP.

Representative Quotes (Correspondence ID): 221
Comments (Comment ID): 645296

Concern Statement: USACE should consider the impacts to agricultural lands as required by the Farmland Protection Policy Act. This includes the conversion of agricultural lands due to an increase in flooding.

Response: USACE acknowledges the concerns relating to the Farmland Protection Policy Act. Federal acquiring of lands for habitat would only be acquired from willing sellers. A description of prime farmland is provided in the Land Ownership Affected Environment, Section 3.10.1 3 of the Final EIS. The effects of federal land acquisition on prime farmland have been evaluated in the OSE sections of Land Ownership (Section 3.10.2) associated with the alternatives. Because the target acreage for land acquisition for early life stage habitat is such a small proportion of the floodplain acres (agricultural floodplain from Ponca to Rulo accounts for 970,332 acres and Rulo to the mouth accounts for 560,839 acres), the land acquisition targets under Alternative 1 represent 0.2 percent and 0.9 percent of agricultural lands in the floodplain in these reaches, respectively. In addition, projected acreages for land acquisition for habitat development under Alternative 3 through 6 would be lower than under Alternative 1 and would represent only a very small fraction of these farmlands. Target acres under Alternative 2 would be the highest of all of the alternatives and would account for 1.6 and 5.4 percent of agricultural lands in the flood plain in the Ponca to Rulo and Rulo to the mouth reaches, respectively. Even under Alternative 2, the land acquisition for habitat development would represent a very small proportion of prime farmland in the four states.

USACE has incorporated additional data, analysis, and results on impacts to interior drainage in the Final EIS. The Land Ownership section of the Final EIS has also been updated to include the percentages of prime farmland in the floodplain of the Missouri River.

If flow actions are considered in the future for implementation, further risk and uncertainty assessment will be conducted prior to implementation.

Representative Quotes (Correspondence ID): 221
Comments (Comment ID): 645294

Concern Statement: The agencies should use the term "flood control" instead of "flood risk management."

Response: The term "flood control" is used when referring to the authorized purposes and the Flood Control Act of 1944. However, in 2008, the Army proposed an update to "flood risk management" to be used agency-wide in briefings, newsletters, and press releases, as well as in budget, management, and policy documents. The update emphasizes the broader risk management activities of USACE to ensure competency in risk assessment and to communicate to the public the nature of flood risks and how they can be managed.

Representative Quotes (Correspondence ID): 221
Comments (Comment ID): 645293

Concern Statement: An assumption presented in the Draft EIS is that land use would not change under different flood conditions. However, flood events have had significant impacts on land use depending on the severity of the event. USACE should estimate these indirect effects (implications of the repeated flooding of cropland on property

taxes, payments in lieu of taxes (PILT), federal tax deductions for flooded areas, and the insurability of impacted property) associated with increased flooding in the Final EIS. USACE has omitted the Environmental Quality (EQ) evaluation from the analysis even though such analysis is required by 1983 Principles and Guidelines. Missouri requests USACE conduct a full Regional Economic Development (RED) analysis and include an EQ evaluation for the Final EIS. USACE has omitted the Environmental Quality (EQ) evaluation from the analysis even though such analysis is required by 1983 Principles and Guidelines. Missouri requests USACE conduct a full Regional Economic Development (RED) analysis and include an EQ evaluation for the Final EIS.

Response: USACE acknowledges these indirect effects of flooding to agriculture. Further explanation of these other indirect effects and analysis has been provided along with additional clarification on the modeling in the Final EIS. In addition, the RED evaluation was updated to qualitatively describe how flooding can affect the loss of property values and increased flood insurance premiums. The RED evaluation uses inputs from the NED evaluation to show the impacts to jobs and income from agricultural damages and the geographic extent of the agricultural (river reaches) and structural damages (counties). The regional economic impacts from agricultural damages include the direct, indirect, and induced impacts (jobs, income, and sales) associated with reduced agricultural revenues. Further RED evaluation was not warranted because the management actions under the MRRMP-EIS would result in small impacts to flood risk management, and in most reaches, on average over the period of record, beneficial impacts to flood damages.

With regards to the comment that Regional Economic Development (RED) impacts were not evaluated in all the river reaches, the NED impacts in the Fort Peak Dam to Lake Sakakawea and the Garrison Dam to Lake Oahe reaches had less than a \$250,000 increase in agricultural damages in the worst years compared to No Action. As a result, the jobs and income evaluation for these reaches associated with agricultural damages were not conducted because less than two annual jobs would be affected in the worst difference years. The locations and magnitudes of the agricultural and structural damages were added to the RED section in the Final EIS to provide better context on the distribution of impacts.

The impacts for flood risk and interior drainage are discussed with the NED, RED, and OSE accounts (see Section 3.12.2) of the Final EIS). The topics evaluated under the EQ account include Fish and Wildlife (Section 3.5), Other Special Status Species (Section 3.6), Water Quality (Section 3.7), Air Quality (Section 3.8), Cultural Resources (Section 3.9), and Ecosystem Services (Section 3.23), Pallid Sturgeon (Section 3.3), and Least Tern and Piping Plover (Section 3.4).

Comments (Comment ID): 645283, 645278

Concern Statement: USACE should include a comprehensive flood risk assessment in the Final EIS.

Response: The current study methodology, which employs an 82-year period of record, is suitable for alternative comparison and providing an indication of change in flood risk. If the Management Plan moves forward with a flow action, further risk and uncertainty evaluation will be conducted per USACE requirements. The level of additional analysis will be based on USACE guidance and requirements and will identify the change in

reservoir pool probability, reservoir release frequency, river stage-frequency, and river stage-duration.

Representative Quotes (Correspondence ID): 197
Comments (Comment ID): 645282

Concern Statement: The NOAA Weather Prediction Center routinely verifies quantitative precipitation forecast (QPF) performance. The months in which Alternatives 2, 4, 5, and 6 would have a flow event to have less than a 50 percent accuracy for even a 0.5-inch rainfall event. Therefore, USACE cannot rely on forecasts as the deciding factor in determining whether a flow event should be conducted.

Response: As a means of reducing the risk of downstream flooding during an ESH release or spawning cue, a QPF will be used to forecast flows on the Missouri River. It is recognized that QPFs are not always realized, but it adds an additional level of precaution. Since the current analysis does not utilize QPFs, the flood risks described in the Final EIS would only be reduced if a QPF was implemented during real-time operations of an ESH release or spawning cue.

Representative Quotes (Correspondence ID): 197
Comments (Comment ID): 645257

Concern Statement: The floodplain connectivity targets are only evaluated under Alternative 2 but not under Alternatives 3–6. The geographic footprint for analyzing floodplain connectivity probably should be the Hydrologic Unit Code (HUC) 6 watersheds contiguous to the Missouri River.

Response: Floodplain connectivity for the existing condition was evaluated with results tabulated within the Final EIS, refer to the supporting document HEC-RAS Alternatives Report. The results illustrate that the existing floodplain connectivity acres equals 147,652 acres. Since this acreage surpassed the Alternative 2 floodplain connectivity target of 100,000 acres, no changes were made to increase floodplain connectivity for Alternative 2. However, it should be noted that the floodplain connectivity acres are for the existing condition and would pertain to all alternatives.

Representative Quotes (Correspondence ID): 166
Comments (Comment ID): 644885

Concern Statement: The economic models used for the Draft EIS have yet to be approved by USACE HQ.

Response: The Hydrologic Engineering Center Flood Impact Analysis (HEC-FIA) model used to assess flood risk management impacts associated with the Management Plan alternatives was approved as a USACE certified model prior to the Management Plan study. The Navigation model was developed specifically for the Management Plan. The Navigation model was approved for use for the Management Plan by the USACE Office of Water Project Review on March 7, 2017.

Representative Quotes (Correspondence ID): 176
Comments (Comment ID): 644761

Concern Statement: Coordination of flood fighting activity becomes increasingly critical and costly as river stages increase due to increased manpower, pump station operation, stop log and sandbag gap closure, levee patrolling, etc.

Response: USACE acknowledges that flood fighting is critical and can be costly. These costs have been evaluated to the extent possible for the flood risk management impact analysis and are included as emergency costs for the analysis. Further discussions of the emergency costs are included in Section 2.4, National Economic Development Methodology, of the “Flood Risk Management Environmental Consequences Analysis Technical Report.”

Representative Quotes (Correspondence ID): 156
Comments (Comment ID): 644480

Concern Statement: Evaluation of flood impacts under Alternative 2 and 4 in the Garrison and Oahe reach do not make intuitive sense. Counties showing the greatest impacts are on reservoirs which have flood control structures while counties with the greatest populations are in the headwaters of Lake Oahe and showing much lower levels of flood risk.

Response: USACE is aware that there was an error in the translation from the modeling impacts to the correct counties. This error has been corrected and the county level impacts have been correctly displayed in the Final EIS.

Representative Quotes (Correspondence ID): 239
Comments (Comment ID): 641803

Concern Statement: USACE should model the impacts of the one-time test pulse as described under Alternative 3.

Response: The Missouri River system as currently operated provides substantial flood risk management to the entire basin. The current hydrology, hydraulics, and economic analyses shows the potential for some negative impacts to flood risk management for alternatives that include changes in reservoir flow releases. Additional hydrology, hydraulic, and economic analyses would be conducted if adaptive management identifies the need for future flow measures. The level of additional analysis will be based on USACE guidance and requirements and will identify the change in reservoir pool probability, reservoir release frequency, river stage-frequency, and river stage-duration.

Representative Quotes (Correspondence ID): 85
Comments (Comment ID): 636791

Concern Statement: The RED section should mention that the management of the reservoirs that has the potential to cause flooding events.

Response:

The Missouri River Mainstem dams, levees, and BSNP greatly reduce flood risk, relative to natural conditions. The MRRMP-EIS compares how different alternative plans would differ in terms of residual risk. Direct damages to structures, contents, infrastructure, crops, etc. were analyzed to characterize these differences in residual flood risk in terms of NED. The RED analysis captured the extent to which the direct damages of flooding can lead to losses in regional jobs and/or income. Again, much like the NED analysis, the RED analysis was focused on comparing alternative plans in terms of residual risk.

Comments (Comment ID): 645632

Concern Statement: USACE should assess the potential flood risk to downstream reaches of the Missouri River caused by heavy local precipitation in the spring and fall following a release from Gavins Point Dam.

Response: As a means of reducing the risk of downstream flooding during an ESH release or spawning cue, a quantitative precipitation forecast (QPF) will be used to forecast flows on the Missouri River. It is recognized that QPFs are not always realized, but it adds an additional level of precaution. Since the current analysis does not utilize QPFs, the flood risks described in the Final EIS would only be reduced if a QPF was implemented during real-time operations of an ESH release or spawning cue.

Representative Quotes (Correspondence ID): 132, 142
Comments (Comment ID): 633878, 633830

Concern Statement: The Final EIS should include an analysis of impacts to interior drainage during full service navigation flows.

Response: The EIS evaluated the effects to resources, including interior drainage, by examining the potential impacts from a range of flows represented by an 82-year period of record. For interior drainage, this involved detailed H&H and economic modeling of four sites in addition to an analysis that determined the number of days per year that river stages exceeded flap gate elevations for over 100 drainage sites. The period of record contains multiple instances of full service navigation flows that are considered with the interior drainage analysis.

AE1300 *Affected Environment: Hydropower*

Concern Statement: The Hydropower Affected Environment suggests that grain-drying machinery is operated in the summer when this process occurs in the fall season.

Response: The Hydropower Affected Environment section was updated in the Final EIS to reflect this correction.

Representative Quotes (Correspondence ID): 242
Comments (Comment ID): 645595

EC1300 *Environmental Consequences: Hydropower*

Concern Statement: There seem to be some inconsistencies with the hydropower results. Page Number: 3.1.3, p. 11, Table 1 Comment: This table generally shows the highest energy values for the month of February with the July and August values being significantly lower. In Section 3.13.1.4 on page 3-331 of the Draft EIS, including Figure 3-54 show the lowest demand and generation in February, with the peak in August. An explanation should be provided as to why the highest energy value occurs in the lowest demand month.

Response: The energy values shown in Table 1 were updated to FY 2018 price level and use an additional year of SPP data in the Final EIS. However, those values are intended to represent a replacement cost of energy for the region. In the case of this system, a decrease in hydropower is most likely to be replaced by thermal power. Figure 3-54 is intended to show the average monthly generation for the Missouri River hydropower

system. One simplifying assumption made for the purpose of the model is that high hourly energy prices are associated with high hourly generation periods within the daily blocks but the energy values used are intended to demonstrate a price for an additional MWh of demand in a primarily thermal system. It does not necessarily follow that lower hydropower generation months will have low energy costs.

Additionally, given that many are moving to use relatively low-cost natural gas for thermal power, but natural gas is also used to fuel furnaces in the winter, it follows that recent energy prices would spike in the colder months, especially in an area where natural gas is a large part of the overall system.

The EIS was updated to provide additional explanation to make this distinction clear and explain why energy prices in the winter may be higher than expected.

Representative Quotes (Correspondence ID): 1
Comments (Comment ID): 645688

Concern Statement: The consideration of only one or two years in the hydropower evaluation (pp. 34-37 in technical report) is a major flaw in the analysis because each year could be affected given a different release schedule.

Response: All years for the period of record are considered in the NED analysis. For the purposes of the RED analysis, the original approach was to consider the impact to a “typical” year (in this case 2012) and a drought year as historically identified. The Final EIS includes an average of all of the years of the period of analysis to use for comparison.

Representative Quotes (Correspondence ID): 1
Comments (Comment ID): 645693

Concern Statement: It is difficult to determine from the information provided in the “Hydropower Environmental Consequences Analysis Technical Report” (pages 25-27) if the power generation reported was properly calculated. It appears that there are some inconsistencies between the dam releases and the power plant cfs capacity. For example, Garrison releases for Alternative 4 are 42,500 cfs while the power plant capacity is 41,000 cfs. It is also difficult to understand if the analysis made the assumption that there would be a market for this power (during release periods) at all times, and if so, this would underestimate the impacts. It is suggested that USACE include a chart or table showing volume of water that is discharged for each power plant without generating power for each alternative.

Since the releases through the power plants are higher than the plant capacity, USACE would have to implement spillway or outlet work releases. It was recommended that USACE coordinate with state agencies (South Dakota Game Fish and Parks) to study how these releases affect fisheries resources.

Response: One assumption made by the Missouri River HBC model is that there is always a market for power. This assumption has been made more explicit in the document and added to Section 2.2 Assumptions, along with the caveat that this may result in underestimated impacts if an alternative were to shift power production to a time when there wasn’t a market for power. Additionally, the limits of the power plant capability are taken into consideration when modeling the hydropower results. Additional information has been added to the Methodology section to make the capabilities used by the model more explicit.

Given the clarifying description that was added with regard to the assumptions and modeling parameters, a table showing the volume of water discharged that is greater than the capacity of the plant should not be necessary in the “Hydropower Environmental Consequences Analysis Technical Report.”

Additional studies would need to be done in order to determine spillway and outlet release impacts on fisheries.

Comments (Comment ID): 645691, 646981

Concern Statement: The analysis in the “Hydropower Environmental Consequences Analysis Technical Report” should present the dams from upstream to downstream, and not in alphabetical order as currently presented in the report.

Response: The tables in the final draft were updated to display the dams from upstream to downstream rather than alphabetically.

Representative Quotes (Correspondence ID): 1
Comments (Comment ID): 645690

Concern Statement: The air emissions analysis conducted for the hydropower evaluation presents changes in carbon dioxide and other pollutants, but does not analyze the financial impact to offset or mitigate the environmental consequences of using natural gas compared to hydropower.

Response: An estimate of the financial impact of these shifts is provided using the U.S. Environmental Protection Agency’s Social Cost of Carbon for each alternative in this section. This estimate is intended to represent the potential financial impact of using thermal power sources.

Representative Quotes (Correspondence ID): 107
Comments (Comment ID): 644269

Concern Statement: The hydropower results for Alternative 6 (Section 5.1, page 34, Table 11 in the “Hydropower Environmental Consequences Analysis Technical Report”) do not appear to be accurate compared to other alternatives. In addition, Alternative 1 may not be a reasonable reference alternative.

Response: The results shown for Alternative 6 are unusual most likely because only one reference year, intended to represent a typical year in the existing condition, was used for the analysis rather than an average over the period of record as in the earlier sections. This analysis now includes an average over the period of record.

USACE believes the No Action alternative is a reasonable reference case and meets the intent of including a No Action alternative in the planning process. The No Action simulation represents the current reservoir operations under the current basin conditions. Although the modeled results for each alternative will not capture all of the real-time decisions and adjustments, the impacts provide an assessment of the differences between modeled alternatives. The models and modeling results used in this effort were reviewed extensively by experts internal and external to USACE. The limitations and intended uses of the models have been well documented in the EIS and technical reports.

Representative Quotes (Correspondence ID): 107
Comments (Comment ID): 644261

Concern Statement: Since the dams were built, aggradation has caused the channel capacity in downstream in the Garrison reach to decrease. Implementing additional actions that exacerbate the aggradation will affect hydropower production over time. As sediment accumulates in the delta, releases will have to decrease in order to avoid exceeding channel capacity, especially during the winter when river ice cover causes a 5- to 7-foot stage increase. The Hydropower Environmental Consequences section indicates that mechanical construction of ESH is not anticipated to impact hydropower under any of the alternatives. However, if ESH construction causes more sediment to accumulate over time in the delta regions of inter-dam reaches, especially in the downstream of Garrison reach, it would affect hydropower production.

Response: Further evaluation of aggradation and degradation can be found in the River Infrastructure and Hydrologic Process section. The year 15 modeling results were developed to address aggradation concerns.

Representative Quotes (Correspondence ID): 239
Comments (Comment ID): 642484, 642392

Concern Statement: The hydropower evaluation likely underestimates the adverse impacts to hydropower for the following reasons. First, the energy prices rely on only two years of SPP data, which is a short period to rely on for a long-term projection of power prices. Second, with sufficiently large reductions in power generation, Western Area Power Administration (WAPA) could change its contracts with the purchasing utilities, which would necessitate the utilities constructing new resources rather than relying on short-term fluctuating market purchases. The construction of new resources should be included in the analysis. USACE appears to estimate resource construction costs to replace the capacity of the reduced hydroelectric generation, but not for reduced energy output. Finally, the hydropower evaluation should quantify the impacts to ancillary services, which are only described qualitatively, and the potential impacts to reliability and grid stability.

Response: The Final EIS has addressed these concerns with additional discussion of these items and how this could influence the potential impacts. WAPA has only been in SPP since 2015, so there are a couple of years of applicable data available at this time.

The capacity analysis is intended to capture the costs of building additional resources to maintain the system capacity on average over the long term. Estimating replacement resources for energy loss could result in a “double-counting” of the potential impact at this time. An additional explanation and description of the energy and capacity analysis has been added to the Final EIS.

Given the relatively small impact estimated for the recommended alternative, it was determined that additional quantitative analysis related to ancillary services, reliability, and grid stability was not necessary. Additional discussion has been included to note the potential impact associated with these categories could be potentially understated.

Representative Quotes (Correspondence ID): 134, 172
Comments (Comment ID): 641813, 640596

Concern Statement: Reductions in renewable hydropower generation would be costly for CMEPC member cooperatives and rural customers and would result in a significant increase in the output of carbon dioxide from replacement thermal resources. In addition, Iowa based utilities, along with approximately 300 other consumer-owned utilities in the Missouri River basin, also depend on the Missouri River as the Western Area Power

Administration WAPA supplies electric power generated by six hydroelectric facilities located on the river to the utilities. When WAPA cannot generate enough hydroelectric power to fulfill its contractually obligated agreements due to low water, WAPA must go to the open market and purchase electricity, often at higher costs, which are passed on directly to the consumer-owned utilities that receive electricity from WAPA. Nebraska Public Power District also purchases power from WAPA and has similar concerns.

Response: The concern about a loss in power is noted and the substance of this comment was added to the Final EIS to help further describe the extent of the potential impacts.

Representative Quotes (Correspondence ID): 107, 134, 224
Comments (Comment ID): 640559, 644395, 643783

Concern Statement: Many of the alternatives reduce power generation and the availability of replacement market power and transmission capacity was not analyzed, and as a result, the hydropower and thermal power impacts are understated. In addition, the cumulative or coupled impact of the simultaneous reductions in hydropower and thermal power generation on power markets (prices), energy availability, system reliability, and grid stability is not adequately analyzed in the hydropower and thermal power evaluation. The Final EIS should evaluate whether the alternatives, especially alternative 2, could lead to brown outs or black outs at critical periods for crops and human life.

Response: The assumptions and potential for understated impacts due to the availability of replacement market power and transmission capacity have been further described in both the hydropower and thermal power technical reports in the Final EIS. Impacts to both thermal and hydropower power generation in peak season months (July, August, January and February) were assessed to determine if coupled impacts would occur under the alternatives. Interviews were conducted with representatives from SPP and MISO to better understand these impacts. The reports have been updated to provide additional information on the potential for coupled effects and its associated impacts on power markets, energy availability, system reliability, and grid stability from simultaneous reductions in thermal power and hydropower.

Comments (Comment ID): 641810

AE1400 *Affected Environment: Irrigation*

Concern Statement: The discussion on why there are no irrigation intakes in Iowa, Kansas and Missouri is confusing. Are there are no irrigation intakes or do these states not require

intakes be permitted? Also, is there only one intake per permit (i.e., clarify the relationship between permits and intakes)?

Response: Based on conversations with the Divisions of Natural Resources in Iowa, Kansas and Missouri and local agricultural extension specialists, our understanding is that irrigation in these states is highly isolated. Permitted irrigation intakes in these states are typically used infrequently. The project team thus concluded that any impacts that may occur from the MRRMP alternatives to irrigation intakes in these three states would be negligible.

A single water permit may have multiple points of diversion (intakes). In fact, multiple water permits may even have a single point of diversion, but applied to different acreages. Typically, a water permit is attached to a particular flow rate and a total volume of water, not to a particular intake. We have clarified the discussion to reflect the relationship between permits and diversion points defined under the various permitting systems used by the states being evaluated.

Representative Quotes (Correspondence ID): 239
Comments (Comment ID): 642504

Concern Statement: The estimate within the EIS of permitted irrigated acres is inaccurate (Table 3.132 and Table 3.133). The Office of the State Engineer's database (same year) reports a total of 61,959 irrigated acres or a difference of thirty percent.

Response: The irrigation analysis was revised to include data from the North Dakota State Engineer's Office for all counties in North Dakota. This includes data on crop patterns and acres irrigated by the Missouri River. The tables in the Section 3.14.1 have been updated to reflect this information.

Representative Quotes (Correspondence ID): 239
Comments (Comment ID): 642506

Concern Statement: Information and data included in Table 3-133 appears to be incorrect. According to data maintained by the State of North Dakota, there are 265 irrigation intakes and 328 points of diversion for 251 surface water permits on the Mainstem of the Missouri River in North Dakota, each of which has one or more pumps.

Response: The irrigation analysis was revised to include data from the North Dakota State Engineer's Office for all counties in North Dakota. This includes data on crop patterns and acres irrigated by the Missouri River. The tables in the Section 3.14.1 have been updated to reflect this information.

Representative Quotes (Correspondence ID): 239
Comments (Comment ID): 642507

Concern Statement: The Irrigation section should include a discussion of both gross amount of water pumped from the Missouri River and the net amount applied to fields. The difference is that net amounts of water applied accounts for loss in conveyance, wind drift, evaporation, deep percolation, and runoff.

Response: The project team choose to evaluate only gross water applied to fields as the data on conveyance, wind drift, evaporation, deep percolation, and runoff for all areas included in the irrigation analysis was not available that would allow net water amounts to be estimated. For this analysis, we estimate only the gross amount of water drawn

from the Missouri River as reported by permit information, and base out analysis on changes to the gross amount of water available.

Representative Quotes (Correspondence ID): 186
Comments (Comment ID): 641534

EC1400 *Environmental Consequences: Irrigation*

Concern Statement: Additional information should be provided on the criteria used to select counties for additional analysis. The results show total number of days that intakes are impacted but would be better explained as days per year, maximum or minimum days, or percent change in operation.

Response: The discussion on the criteria used to select counties for further analysis was revised with additional detail in Section 3.0 of the “Irrigation Environmental Consequences Analysis Technical Report.” While the data can be displayed in multiple ways the project team felt that these particular criteria were most appropriate for the screening analysis.

Representative Quotes (Correspondence ID): 186
Comments (Comment ID): 641529

Concern Statement: The discussion of irrigation impacts should disclose any inequities that may occur with the distribution of impacts. In other words, some counties are experiencing higher impacts than others and that should be explicit in the results. The description of significance of impacts should also be re-evaluated.

Response: The analysis and results included in the EIS includes a discussion of impacts by county in the NED analysis. While we do not include the NED results in the RED results, the RED results on a per-county basis are proportional to the NED results on per-county basis and can be inferred. It is true that the impacts are not distributed equally across the counties and the text in Chapter 3 highlights some of those disproportionate impacts in the results.

Comments (Comment ID): 642678, 642661, 642534

Concern Statement: The assumptions associated with the crop patterns in Williams County need to be revisited. The analysis refers to irrigated wheat and losses associated with producing wheat. The state engineer keeps records on irrigated acreage and show a small percentage of total acres in wheat. Corn and sugar beets are grown more widely in this county than wheat. If the crop patterns under Alternative 1 are inaccurate, this may lead to an underestimate in impacts under the management plan alternatives.

Response: The project team revisited the data and assumptions used to evaluate impacts to irrigation in Williams County (and other counties in North Dakota). The irrigation (Section 3.14) was revised to include data from the North Dakota State Engineer’s Office for all counties in North Dakota. This includes data on crop patterns and acres irrigated by the Missouri River. This includes the crop patterns assumed for Williams County.

Representative Quotes (Correspondence ID): 239
Comments (Comment ID): 642519

Concern Statement: Need to define what is meant by “significant” when describing the percentage of irrigated acres used to determine whether a county was included in analysis. The Missouri River represents 90 percent of surface water supply in North Dakota with scarce groundwater resources in western North Dakota. The river is a major source of water for irrigation operations in North Dakota.

Response: The methodology section in the “Irrigation Environmental Consequences Analysis Technical Report” (Section 3.0) was revised by removing references to significance of criteria related to the percentage of irrigated acreage using water from the Missouri River. This section was revised to clarify how the criteria were used to select counties for further analysis.

AE1500 *Affected Environment: Navigation*

Concern Statement: The discussion of the navigation checks on March 15 and July 1 are inaccurate in the Draft EIS. The system volume check on March 15 determines navigation service level which could be full service, minimum service, or no service (or a service level in between). The July 1 system volume check determines season length and service level for the remainder of the navigation season.

Response: Section 3.15.1 was updated to state: “The decision on length of the navigation supported season is typically made during the July 1st storage check if a navigation season is underway.” The exact guidance provided in the Master Manual is described in Section 2.15.1.2 for Navigation Service Level and 3.15.1.3 for the Navigation Season Length. According to Table 3-154, Page VII-4 of the Master Manual “Normal and Conservation System regulation involves a check on the amount of System water in storage on March 15 to determine if a navigation season will be provided that year, and if so, the service level to provide for the first part of the navigation season. The System water-in-storage is checked again on July 1 to determine the service level for the remainder of the navigation season and the ending date or length of the navigation season.

Comments (Comment ID): 642679

Concern Statement: The navigation analysis was based on 2014 data with little or no research in changing movements from the gulf ports, the emergence of regional agricultural export markets to Asia, increased movement of petrochemicals and petroleum products by water and the effects of an expanded Panama Canal on shipping volumes. This will enable central U.S. shippers alternative access to U.S./Asia routes and will influence freight rates in favor of agricultural products from the Midwest.

Response: The navigation analysis was updated to use the most current data and information available, 2016 Waterborne Commerce Statistics Center data. In addition, an evaluation was also undertaken to estimate the navigation NED benefits, specifically the transportation rate savings, if commercial tonnage was at 1994 levels, a considerable increase of over 3 times the 2016 tonnage levels (see Section 4.1.1. of the “Navigation Environmental Consequences Analysis Technical Report”). Additional projects and actions were added to the list of cumulative actions that could affect Missouri River navigation (i.e., export markets to Asia, increased movement of petroleum products,

expanded Panama Canal). The cumulative impacts of these actions and projects, along with the impacts of the MRRMP-EIS alternatives on navigation are described in Section 3.15.2.4, Navigation Environmental Consequences, Cumulative Impacts.

Representative Quotes (Correspondence ID): 156
Comments (Comment ID): 44663

Concern Statement: With rail capacity becoming less and an over-the-road driver shortage showing no abatement, there is evidence that inland waterways are becoming critical in the movement of freight. The first full year of operating Port KC (the Kansas City port facility) was tremendously successful. These regional advances in navigation should be acknowledged, discussed and studied in the Draft EIS.

Response: The navigation analysis used the most current data and information available at the time it was completed, 2016 Waterborne Commerce Statistics Center data. In addition, an evaluation was also undertaken to estimate the navigation NED benefits if commercial tonnage was at 1994 levels, a considerable increase of over 3 times more than the commercial tonnage moved in 2016 on the Missouri River. Additional information and discussion were added to the affected environmental section (Section 3.15.1) regarding the re-opening of the Port of Kansas City. Cumulative projects, actions, and economic trends that can affect navigation are described in the Cumulative Impacts Section 3.15.2.4. Cumulative impacts to navigation include the impacts of the cumulative actions and projects combined with the impacts of the MRRMP-EIS alternatives.

Representative Quotes (Correspondence ID): 156
Comments (Comment ID): 644669

Concern Statement: Flow changes have a direct impact on Missouri River navigation opportunities. Navigation on the Missouri River itself relies on consistent and reliable flows, and the recent return of traffic are testament to the necessity of reliable flows. Prior to the severe disruptions in flows in the late 1990s and early 2000s, towing companies operating exclusively on the Missouri River could obtain five-year contracts from shippers. After the flow changes, all line haul companies working exclusively on the Missouri River went out of business. According to the Missouri Department of Transportation, barge traffic on the Missouri River has been increasing over the last five years, in large part due to reliable flows. The 2015-2016 navigation season was also a productive year for barge traffic on the Missouri River.

Response: The navigation analysis used the most current data and information available at the time it was completed, 2016 Waterborne Commerce Statistics Center data. In addition, an evaluation was also undertaken to estimate the navigation NED benefits if commercial tonnage was at 1994 levels, a considerable increase of over 3 times compared to the commercial tonnage moved in 2016 on the Missouri River. Additional information and discussion on the historic service levels, season lengths, and tonnage shipped on the Missouri River has been added to Section 3.15.1.2, along with a discussion on the importance of navigation reliability for the industry.

Representative Quotes (Correspondence ID): 176
Comments (Comment ID): 644741, 644743

Concern Statement: USACE has designated service levels for its inland waterways across the country. The service level ranks those reaches on a priority level from 1 to 6. This

service level ranking for navigation on the Missouri River should be included in the Final EIS.

Response: It is the project team's understanding that the commenter is referring to the service levels for locks. The six categories are determined for each lock based on the number of lockages per year. The service level is used to shift operational funds and resources from low-use locks to critical maintenance of high commercial use locks. See <http://www.lrp.usace.army.mil/Portals/72/docs/navigation/LockSvcLvls/PublicHandoutFINAL.pdf>.

Because there are no locks on the Missouri River it is not appropriate to include this measurement in the EIS.

Comments (Comment ID): 645550

EC1500 *Environmental Consequences: Navigation*

Concern Statement: The low summer flow under Alternative 2 would have impacts to navigation by causing a split season on the Missouri and adversely impacting the Middle Mississippi River. Low summer flows would drop flows below the Construction Reference Plane (CRP) levels and halt navigation. Navigation would once again become unreliable and the navigation community and the users of the commercial navigation system would suffer negative economic consequences. The low summer flows may also impact the navigation lane where water and power utilities may have to place barges with pumps to reach water.

Response: The navigation analysis included an assessment of all MRRMP-EIS alternatives including Alternative 2, which includes low summer flows. In the years when a low summer flow would be simulated to occur, the analysis assumed a split navigation season and the impacts of the split season were assessed and are included in the Final EIS. During the split season, all tonnage was assumed to be shipped via other modes (truck and rail) and all transportation rate savings associated with shipping commodities via navigation were estimated to be zero. In the low summer flow years, transportation rate savings would be adversely affected, with annual reductions compared to No Action up to \$2 million (compared to \$8 million on average in transportation rate savings over the period of record). Refer to Section 5.3 of the "Navigation Environmental Consequences Analysis Technical Report" for additional detail on Alternative 2. In addition to no navigation during these low summer flow events, there would also be impacts to navigation reliability, with the reduced ability for navigators to secure relatively longer-term contracts (i.e., 5 years) if navigation might be unavailable for approximately 10 weeks in the summer. These impacts are described in Section 3.15.2.1 of the Final EIS, Navigation Environmental Consequences, Alternative 2. The low summer flows may also impact the navigation lane where water and power utilities may have to place barges with pumps to reach water.

Pumps placed in the river to access water for intakes cannot be placed in the navigation channel during the navigation season unless authorized by USACE. In addition, regulations associated with Section 316(b) of the Clean Water Act prevent the use of supplemental pumps on some cooling water intakes on power plants to reduce mortality to fish.

Representative Quotes (Correspondence ID): 27, 33, 65, 145, 168, 176, 195, 205, 216, 228

Comments (Comment ID): 626696, 642102, 646281, 646278, 645576, 645159, 644771, 644735, 642102, 637632, 631570, 628004

Concern Statement: Alternatives with releases have the potential to negatively impact navigation. Flow releases (Spring or Fall) in the range of 60,000 cfs would negatively impact navigation due to high velocities. Spring releases are especially concerning as they would occur during times when natural flows are already high. The Draft EIS incorrectly concludes that Alternative 5, with both full or partial releases do not have an impact on navigation benefits. This is a false conclusion because it does not account for the harvest season and the increased export market on both the Missouri and Mississippi rivers during the fall.

Response: The navigation analysis considered the impacts of all the management alternatives (2 – 6) relative to Alternative 1; the USACE HEC-ResSim modeling simulates the level of navigation service and season length under each of the alternatives. This USACE modeling and associated navigation evaluation includes the impacts of various flow releases under Alternatives 2, 4, 5, and 6. The assessment includes an evaluation when flows exceed 60,000 cfs, which can be detrimental to navigation. The unit transportation rate savings are shown to be lower when flows are above 55,000 cfs for most commodities and lower when flows are above 65,000 cfs for all commodities when compared to full service flows (35,000 to 45,000 cfs). The unit transportation rate savings are described in Section 2.2.2 in the Methodology Section of the “Navigation Environmental Consequences Analysis Technical Report.” Under Alternative 5, there are some small decreases in transportation rate savings in some full fall release years. However, the years with relatively larger adverse impacts under Alternative 5 occur in the years following the fall releases when navigation service levels are lower than under No Action due to lower storage levels in the reservoirs in these years. A discussion of the navigation analysis and impacts associated with each of the alternatives has been updated to describe these impacts and is provided in the Section 3.15.2.2, Navigation, of the Final EIS, and additional details are provided in the “Navigation Environmental Consequences Environmental Consequences Analysis Technical Report.”

Prior to a release being implemented, USACE would notify the navigation industry and other River stakeholders of the release. An evaluation of the impacts of the MRRMP-EIS alternatives on flood risk is provided in Section 3.12 of the Final EIS, Flood Risk Management and Interior Drainage.

Comments (Comment ID): 645913, 645177, 645584, 645161, 644756, 645579

Concern Statement: The one-time test pulse under Alternative 3 would negatively impact navigation.

Response: The one-time spawning cue test (Level 2) release that might be implemented under Alternative 3, the preferred alternative, was not included in the hydrologic modeling for these alternatives because of the uncertainty of the hydrologic conditions that would be present if implemented. Hydrologic modeling for Alternative 6 simulates reoccurring implementation (Level 3) of this spawning cue over the wide range of hydrologic conditions in the POR. Therefore, the impacts from the potential implementation of a one-time spawning cue test release would be bound by the range of impacts described for individual releases under Alternative 6. This modeling is a reasonable representation of the impacts that could occur to navigation under the one-time spawning cue test. A summary of the potential impacts under Alternative 6 has been provided in the

navigation section under Alternative 3 in the Final EIS, Section 3.15.2.2, Navigation Environmental Consequences.

Representative Quotes (Correspondence ID): 176
Comments (Comment ID): 645774

Concern Statement: The impact of the alternatives on water compelled rates needs to be modeled in the Final EIS.

Response: USACE contracted with the University of Tennessee, Center for Transportation Research to conduct a quantitative precipitation forecast (QPF) qualitative assessment of water-compelled rates associated with Missouri River navigation. The University of Tennessee, Center for Transportation Research report provides a historical context of waterway and rail traffic along the Missouri River, noting the relatively recent issues with waterway reliability for navigation; describes past rail regulatory reforms; provides previous estimates of water-compelled effects; and describes the current rail environment that could have implications for these issues. The issues are complicated surrounding water-compelled rates and the dynamic economic conditions and context of the rail industry create uncertainties regarding the effect of Missouri River navigation on railroad pricing. However, the authors conclude that unless expectations regarding the Missouri River's reliability and long-run availability for navigation are reversed, water-compelled railroad rates attributable to Missouri River commercial navigation seem improbable. Further details are discussed in the "Missouri River Water-Compelled Railroad Rates: Review and Qualitative Update" available online (www.moriverrecovery.org).

Comments (Comment ID): 645638, 645250, 645169, 645261, 645608

Concern Statement: The independent panel (ISETR) needs to include an economist with experience in economic navigation models.

Response: USACE believes the ISETR panel has a range of expertise appropriate for providing a thorough review of the range of resources examined in the EIS including navigation. This is evidenced by the detailed feedback on Human Considerations Objectives, Metrics, Methods, and Models including navigation and navigation-related comments received from the independent external peer review of the EIS. Panel areas of expertise and independent reports are provided online at: <https://projects.ecr.gov/moriversciencepanel/TechReviewPanel.aspx>

Representative Quotes (Correspondence ID): 168, 197, 228
Comments (Comment ID): 645575, 645251, 645178

Concern Statement: The OSE analysis for navigation needs to consider changes in traffic congestion, public safety on roads, road and bridge repair costs, and travel costs with modal shifts in transportation.

Response: The navigation OSE analysis considered the impacts on air emissions due to potential modal shifts to land under each alternative. In addition, changes in transportation rates savings is evaluated as part of the NED analysis. For the Final EIS, the project team has included a discussion of the potential OSE impacts related to traffic congestion, public safety on roads, and road and bridge repair costs in the OSE subsections of the alternatives in Section 3.15.2, Navigation Environmental Consequences, of the Final EIS. On average, over the period of record, there would be

an estimated 5,400 tons diverted off of the waterway to alternate modes under Alternative 4 compared to Alternative 1, the alternative with the largest impacts. If we assume that all of the traffic would be shipped by truck, there would be an estimated additional 208 trucks per year under Alternative 4 on the highways. Given the small number of additional trucks over a large region, and that some of the tonnage would be shipped via rail, a qualitative description of the public safety and health aspects associated with higher volumes of truck transportation was deemed appropriate.

Representative Quotes (Correspondence ID): 228
Comments (Comment ID): 645609

Concern Statement: The assumption that the navigation ends when the navigation season (more accurately defined as flow support) officially ends is incorrect. Shippers will continue to use the river as long as adequate flows and weather conditions persist.

Response: Navigation on the Missouri River is limited to the normal ice-free season, with a full-length flow support season of 8 months, which normally extends from April 1 through December 1. The navigation analysis evaluated the impacts to transportation rate savings only during the navigation season, when USACE provides navigation flows if System storage criteria are met. The season lengths for each alternative were based on the hydrologic and hydraulic model outputs over the period of record and the criteria for season length determination described in the Master Manual and in Section 3.15.1, Navigation Affected Environment of the Final EIS. USACE does not provide navigation flows during the non-navigation season and when the navigation criteria indicate that the navigation season should be shortened. Given these conditions, the analysis showed support for navigation flows longer in some years than others. Because the same season length criteria is applied to all alternatives, including Alternative 1, the project team does not believe relative difference in NED benefits among alternatives have been underestimated.

Representative Quotes (Correspondence ID): 176, 228
Comments (Comment ID): 645581, 644757

Concern Statement: Change the statement in EIS "Alternative means of achieving species objectives are evaluated for their effects on navigation." To "The effects of navigation on species objectives are evaluated" considering the lack of commercial traffic on the river.

Response: The EIS evaluates the impacts of the management actions under each of the alternatives on human considerations that have been noted as important. Thus, we believe that the way the statement is noted is appropriate. Overall, the plan strives to balance meeting the needs of the species while minimizing impacts to other resources that utilize the river.

Representative Quotes (Correspondence ID): 242
Comments (Comment ID): 645557, 645452

Concern Statement: The navigation impacts analysis must take into consideration shifts from waterborne commerce to rail or truck under the Intermodal Surface Transportation Efficiency Act (ISTEA). ISTEA requires linked connectivity between modes, productive growth, reduced energy consumption, reduced air pollution, reduced traffic congestion, and competition.

Response: The National Intermodal Transportation System includes all forms of transportation in a unified, interconnected manner, including the transportation systems of the future,

and the purpose of the inter-connect system is to reduce energy consumption and air pollution while promoting economic development and supporting the Nation's preeminent position in international commerce. The Intermodal Surface Transportation Efficiency Act (ISTEA) is described in Section 3.15.2.1 in the Navigation Environmental Consequences, Methodology, Other Social Effects of the Final EIS. In addition, the project team has included a discussion of the potential OSE impacts related to air emissions, traffic congestion, public safety on roads, and road and bridge repair costs in the alternatives sub-sections of Section 3.15.2 in the Final EIS, Navigation Environmental Consequences. The project team is not aware of any specific requirements under ISTEA that must be addressed in the navigation section.

Representative Quotes (Correspondence ID): 221

Comments (Comment ID): 645295

Concern Statement: The navigation industry requires predictability and adequate flow support. Sudden changes in flow support can be economically impactful and even dangerous. These characteristics are not factored into the Missouri River navigation economic assessments conducted in the Draft EIS. In addition, the Draft EIS does not present a summary table of navigation performance (service level and season length) among the alternatives for the 82-year dataset.

Response: For navigation, the transportation rate savings account for the changes in economic benefits/savings given changes in service level and season length for each alternative. If USACE were to implement a flow action under the management plan, advance notice would be provided of the anticipated action. Given the importance of reliability to navigation operations, the project team added a reliability discussion to the Affected Environment section for navigation, in Section 3.15.1.2, Navigation Affected Environment of the Final EIS and impacts to navigation reliability associated with MRRMP-EIS alternatives have been described in Section 3.15.2.1 of the Navigation Environmental Consequences sections of the Final EIS.

In addition, summary tables have also been presented in the "Navigation Environmental Consequences Analysis Technical Report" that show the service level and season length by alternative over the period of record (Section 3.0).

Representative Quotes (Correspondence ID): 197, 222

Comments (Comment ID): 645263, 644805

Concern Statement: It is inappropriate to include routine repair, replacement, and rehabilitation costs (R, R, and R) in the navigation analysis while omitting similar costs for other USACE projects being analyzed. For instance, each of the Mainstem dams has annual operation and maintenance costs that were not included in any of the analyses.

Response: The project team included non-routine repair, replacement, and rehabilitation costs for the HC resources if it was determined that the management alternatives would influence those costs beyond normal operations and maintenance. For instance, additional operations and maintenance costs beyond normal operations was considered for boat ramps as part of the recreational analysis. Since flow actions under the management plan alternatives could affect management of the navigation channel, the analysis considered changes in repair, replacement, and rehabilitation costs to maintain the channel associated with changes in river flows and navigation service levels.

Representative Quotes (Correspondence ID): 197

Comments (Comment ID): 645262

Concern Statement: USACE needs to properly account for the value of goods shipped on the Missouri River in the Final EIS.

Response: Per USACE guidance (ER 1105-2-100 Planning Guidance Notebook), the NED benefits for navigation account for the change in transportation rate savings required to transport commodities, not the value of the commodities. However, the types of commodities transported on the Missouri River are detailed in the Navigation Affected Environment section of the EIS, Section 3.15.1, including consideration of oversized equipment and goods.

Representative Quotes (Correspondence ID): 197
Comments (Comment ID): 645260

Concern Statement: USACE failed to analyze the economic impact of the management actions on navigation in the Middle Mississippi (St. Louis to Ohio River).

Response: USACE has updated the navigation evaluation to estimate the navigation NED impacts associated with anticipated changes in Middle Mississippi River navigation under the MRRMP-EIS alternatives. The evaluation used input from industry sources on tow configurations and barge loading at various low flow thresholds; operating costs per tow; and tow speeds to estimate the change in NED costs associated with the MRRMP-EIS alternatives. The Mississippi River evaluation is described in Section 3.24.5, Navigation Mississippi River Impacts of the Final EIS.

Representative Quotes (Correspondence ID): 173, 197
Comments (Comment ID): 645249, 641388

Concern Statement: The Flood Control Act of 1944 authorized USACE to govern the U.S. waterways and requires USACE to prioritize flood control and navigation as dominant functions of its authority. Though the responsibilities of USACE have increased over time with additional directives from Congress, namely those to assist in protecting endangered species, the new obligations have not diminished the original priorities. While the courts have noted the difficulty in balancing these varied interests, case law is clear that endangered species do not get to take precedence to the detriment of flood control and navigation.

Response: USACE will comply with all laws, statutes and case law when implementing the MRRMP. The Final EIS has evaluated the impacts of the management plan alternatives for both navigation and flood risk management and has been considered in the selection of the preferred alternative.

Representative Quotes (Correspondence ID): 168
Comments (Comment ID): 645189

Concern Statement: All the economic models used to assess the impacts of the proposed alternatives on navigation and flood control have yet to be approved by USACE Headquarters. Until the final models have been adequately reviewed and commented on by stakeholders and MRRIC, no alternative should be chosen.

Response: All models have been through Agency Technical Review and District Quality Control, and they have been approved for use on the MRRMP by USACE. In addition, the analyses and results have been reviewed by the Independent Social Economic Technical Review (ISETR) panel through an Independent External Peer Review (IEPR). The technical reports detail the models, methods, assumptions, data sources and results

and are available as part of the Final EIS documents and online (www.moriverrecovery.org).

Representative Quotes (Correspondence ID): 168
Comments (Comment ID): 645180

Concern Statement: The economic modeling used in the Draft EIS to evaluate navigation impacts utilized data from Master Water Control Manual Missouri River Review and Update Study which is over twenty years old. USACE did not consult with members of the towing industry or its customers to obtain feedback on how to calculate transportation savings and R, R, and R costs in its NED analysis. The RED evaluation appears to be insufficient and lacking in data from the tugboat, towboat and barge industry.

Response: The navigation evaluation used 2018 prices to compute the unit transportation rate savings. Data from the 2002 Transportation Rate Analysis: Master Manual Review provided a basis for the unit rate savings analysis. National and Mississippi River transportation rate savings provided by the USACE Planning Center of Expertise and Risked Informed Economics were reviewed, alongside the updated 2018 transportation rates savings. These transportation rate savings were compared and discussed with navigation economist, Dr. Mark Burton (Burton, pers. comm. 2017). Because the Missouri River Master Manual transportation rate savings reflect the shipping characteristics and competitive influences specific to the Missouri River, the updated 2018 rates were most appropriate for the NED evaluation (Burton, pers. comm. 2017).

The navigation RED evaluation estimated how the shift in commercial tonnage from the waterway to alternate overland modes of transportation under the MRRMP-EIS alternatives would affect waterway shippers, port services, and warehousing revenues and associated direct, indirect, and induced jobs and income. The RECONS model, a certified USACE model, which uses IMPLAN© ratios and multipliers to estimate regional economic effects, was used to conduct the evaluation. IMPLAN© is a standard approach to estimate regional economic effects and is widely used by academics, government and industry.

In addition, USACE has updated the navigation evaluation to estimate the navigation NED impacts associated with anticipated changes in Middle Mississippi River navigation under the MRRMP-EIS alternatives. Industry experts were consulted on tow configurations and barge loading at various low flow thresholds; operating costs per tow; and tow speeds. This information from industry experts was used as input to estimate the change in NED costs associated with the MRRMP-EIS alternatives. The Mississippi River evaluation is described in Section 3.24.5, Navigation Mississippi River Impacts of the Final EIS.

Representative Quotes (Correspondence ID): 168, 176
Comments (Comment ID): 645175, 644754

Concern Statement: The Draft EIS includes these years in the period-of-record when artificial government actions negatively impacted navigation during these years. This includes low summer flows in the early 2000s and a large spring rise a few years later to serve as a spawning cue for the pallid sturgeon. These years should be excluded from the modeling, otherwise the benefits of navigation are substantially understated in the Draft EIS. These federal actions discouraged navigation on the river due to reliability

concerns. Navigation on the Missouri River did not begin to recover until recent years when USACE provided reliable flows.

Response: The analysis presented in the EIS does not use observed data to assess the alternatives. Each alternative is a modeled result based on the same operations applied to each year of the simulation. The No Action (Alternative 1) does contain the plenary pulse/spawning cue but does not include low summer flows, as simulated in Alternative 2. Impacts associated with implementing or not implementing the spawning cue are shown in the Alternative 1 vs Alternative 3 (Alternative 3 does not include the plenary pulse/spawning cue). Impacts associated with the low summer flows are shown in the comparison between Alternative 1 and Alternative 2.

Representative Quotes (Correspondence ID): 168
Comments (Comment ID): 645174

Concern Statement: Dr. Bray and Dr. Burton concluded that there is not enough traffic on the Missouri River to measure water-compelled railroad rates. This conclusion ignores the fundamental principle of water-compelled rates and does not account for the recent increase and continued growth of navigation on the Missouri River.

Response: The University of Tennessee, Center for Transportation Research report (Dr. Bray and Dr. Burton 2017) provides a qualitative assessment of the impacts of Missouri River navigation on water compelled rates. The report provides a historical context of waterway and rail traffic along the Missouri River, noting the relatively recent issues with waterway reliability for navigation; describes past rail regulatory reforms; provides previous estimates of water-compelled effects; and describes the current rail environment that could have implications for these issues. The issues are complicated surrounding water-compelled rates and the dynamic economic conditions and context of the rail industry create uncertainties regarding the effect of Missouri River navigation on railroad pricing. However, the authors conclude that unless expectations regarding the Missouri River's reliability and long-run availability for navigation are reversed, water-compelled railroad rates attributable to Missouri River commercial navigation seem improbable. Further details are provided in the "Missouri River Water-Compelled Railroad Rates: Review and Qualitative Update" available online (www.moriverrecovery.org).

Representative Quotes (Correspondence ID): 168
Comments (Comment ID): 645170

Concern Statement: The impact analysis of Alternative 2 is contradictory. The Draft EIS states "that the impacts of Alternative 2 would not be significant because the NED decreases in magnitude and percentage change is small; RED impacts would be negligible." However, the Cumulative Impacts section states "Adverse impacts could result in the reduction of the navigation season length for years with the low summer flow, and the potential reduction in service level provided that could occur in the years with the spawning cue pulse. When combined with other past, present and reasonably foreseeable future actions, the cumulative impacts on navigation associated with Alternative 2 would result in a large reduction in navigation benefits." The conclusions in the Draft EIS on the cumulative impacts of Alternative 2 on Missouri River navigation are severe and not one bit negligible contrary to the earlier conclusions.

Response: The environmental consequence section and the cumulative impacts section has been reviewed and updated for consistency across these two sections in the Final EIS

(Section 3.15.2, Navigation Environmental Consequences). The average annual change in navigation NED and RED benefits is likely to be small and adverse under Alternative 2 (0.6 percent average annual decrease in NED from No Action). However, the split navigation seasons during low summer flow events under Alternative 2 would result in large adverse impacts to commercial navigation in those years (up to \$2 million reduction from No Action); when compared to average annual navigation NED benefits of \$8.0 million. A reduction of \$2 million represents a decrease in transportation rate savings of approximately 25 percent. In addition to no navigation during these low summer flow events, there would also be impacts to navigation reliability, with the reduced ability for navigators to secure relatively longer-term contracts (i.e., 5 years) if navigation is unavailable for up to 10 weeks in the summer when water conditions allow for the spawning cue and low summer flow events to be implemented. These impacts are described in Section 3.15.2.2., Navigation Environmental Consequences, Alternative 2. The cumulative impact analysis considers both the cumulative actions or projects as well as with the impacts under the MRRMP-EIS alternatives. Because of the large adverse effects of the low summer flows on navigation under Alternative 2 in those years along with the adverse impacts to navigation long-term planning and reliability, the contribution of Alternative 2 to cumulative impacts could be large and adverse. The impacts to navigation under Alternative 2 would be significant because there would be uncertainty in the provision of navigation service for 10 months when low summer flows would occur, which would add to the variability in hydrologic flooding and drought conditions, leading to potentially unfavorable conditions for the navigation industry. Section 3.15.2.4, Navigation Environmental Consequences, Cumulative Impacts has been updated to reflect a description of these impacts to navigation under Alternative 2.

Representative Quotes (Correspondence ID): 168
Comments (Comment ID): 645160

Concern Statement: The modeling of a range of hydrological conditions for Alternative 6 is not sufficient to address the potential impacts of one-time spawning cue test which includes future hydrological conditions, weather patterns and the possible impacts of climate change.

Response: The one-time spawning cue test (Level 2) release that might be implemented under Alternative 3 was not included in the hydrologic modeling for these alternatives because of the uncertainty of the hydrologic conditions that would be present if implemented. Hydrologic modeling for Alternative 6 simulates reoccurring implementation (Level 3) of this spawning cue over the wide range of hydrologic conditions in the POR. Therefore, the impacts from the potential implementation of a one-time spawning cue test release would be bound by the range of impacts described for individual releases under Alternative 6. This modeling is a reasonable representation of the impacts that could occur to navigation under the one-time spawning cue test. These impacts are described in the Navigation Environmental Consequences section of Alternative 3 of the Final EIS (Section 3.15.2.6). Additional hydrology, hydraulic and economic analyses would be conducted if adaptive management identifies the need for future flow measures. The level of additional analysis will be based on USACE guidance and requirements and will identify the change in reservoir pool probability, reservoir release frequency, river stage-frequency, and river stage-duration.

Comments (Comment ID): 645158

Concern Statement: The impacts of IRC and ESH habitat construction on navigation have not been fully vetted. In the Draft EIS, navigation is given priority over ESH and IRC construction because the design of the habitat itself is supposed to prevent any impacts to navigation. USACE states that if effects to navigation do occur, then the habitat construction would be undone to return to the original use of the channel. This is significant because it means that potentially far less early life stage habitat could be created than each of the alternatives suggest, and that pallid sturgeon goals may not be met. Even if the constructed habitat would have some incidental impact on navigation, USACE should not abandon this management action because it is essential to meet species goals.

Response: The Final EIS does evaluate the impacts of IRC and ESH habitat construction on navigation. The project team concluded that ESH habitat construction would not have an impact on the portion of the river where commercial navigation takes place. This conclusion is based on the assumption that ESH construction would occur upstream of the BSNP. In addition, while it is not known specifically where the actual IRC habitat will be located, USACE will work with stakeholders and navigation interests to minimize impacts to the navigation channel. In addition, site specific analysis (NEPA) would be conducted once these locations are identified and prior to construction. Because planning for habitat construction and design would seek to minimize impacts to other authorized purposes and River uses, it is not anticipated that habitat would need to be removed. The Final EIS Section 3.15.2.1, Navigation Environmental Consequences, Alternatives Mechanical Habitat Construction sections were updated to reflect the above descriptions.

Comments (Comment ID): 645039, 642139, 633922

Concern Statement: Each of the alternatives begins their concluding paragraph with a sentence that says the Alternatives 2, 4, 5, and 6 have negative impacts on navigation and Alternative 3 has a positive impact. The conclusion of each alternative then ends with a sentence saying that those impacts are not significant. This appears to be conflicting conclusions because each adverse impact is either slightly adverse, adverse, or largely adverse. In addition, the fact that Alternative 3 is the only alternative with positive impacts shows a bias towards that alternative, furthering demonstrating an unreasonable range of alternatives.

Response: Navigation on the Missouri River is limited to the normal ice-free season, with a full-length flow support season of 8 months, which normally extends from April 1 through December 1. The navigation analysis evaluated the impacts to transportation rate savings, per USACE guidance (ER 1105-2-100 Planning Guidance Notebook). The evaluation assessed how changes in System storage would affect navigation service levels and navigation season length. The season lengths for each alternative were based on the hydrologic and hydraulic model outputs over the period of record and the criteria for season length determination described in the Master Manual and in Section 3.15.1, Navigation Affected Environment of the Final EIS. USACE does not provide navigation flows during the non-navigation season and when the navigation criteria indicate that the navigation season should be shortened. Given these conditions, the analysis showed support for navigation flows longer in some years than others. Because the same season length criteria are applied to all alternatives, including Alternative 1, the project team does not believe relative difference in NED benefits among alternatives have been underestimated. The navigation NED evaluation showed that on average

there are negligible to small adverse effects to transportation rate savings compared to No Action under Alternatives 2, 4, 5, and 6, and a slight increase in transportation rate savings under Alternative 3 compared to No Action. However, in some years, under Alternative 2, there can be large adverse effects from the low summer flow events. The conclusions sections of the Navigation Environmental Consequences evaluation were updated for consistency with the results described under the alternatives (Section 3.15.2.2.)

Representative Quotes (Correspondence ID): 240
Comments (Comment ID): 645038

Concern Statement: There appears to be a difference in results in the navigation and sand and gravel sections for all the alternatives. An analysis of the impacts of the alternatives on navigation is a permissible consideration. However, USACE overstates those impacts where it analyzes sand and gravel dredging under the topic of navigation as well as under its own category, particularly since the conclusions of the MRRMP-EIS in the Commercial Sand and Gravel Dredging section conflict with the conclusions in the Navigation section.

Response: While commercial sand and gravel dredging is evaluated in two sections of the Final EIS, the project team does not believe the results are contradictory. These two sections evaluated different aspects of the sand and gravel industry, therefore it is expected that results may differ. The commercial sand and gravel dredging section evaluates the impacts of the management plan alternatives on the availability of materials (i.e., sediment accumulation rate) that are dredged and commercially sold as sand and gravel. The navigation section evaluated the impacts of the management alternatives on how river flows and stages would affect the ability to extract and transport the sand and gravel resources dredged from the river. Because these two sections are evaluating different aspects of the sand and gravel industry it is likely that the impact analysis for both may be different. Additional details are described in the "Commercial Sand and Gravel Dredging Environmental Consequences Analysis Technical Report" and "Navigation Environmental Consequences Analysis Technical Report" available as part of the Final EIS and online (www.moriverrecovery.org).

Representative Quotes (Correspondence ID): 240
Comments (Comment ID): 644965, 644964, 644963, 644961

Concern Statement: When discussing the impacts that the ESH construction of Alternative 2 would have on the sand and gravel dredging, USACE erroneously states "each project will be designed to not impact other authorized purposes including sand and gravel dredging as described in Section 2.5.3.1. Sand and gravel dredging is not a congressionally authorized use of the Missouri River and should afford no special protection in the development of alternatives. Therefore, the sand and gravel dredging industry should not be given undue consideration in the MRRMP-EIS. If anything, reducing dredging activity would seem to accrue benefits to species protection.

Response: The reference to sand and gravel dredging as an authorized purpose has been removed. However, the EIS examines a variety of human considerations, some of which are authorized purposes and others that are not.

Representative Quotes (Correspondence ID): 240
Comments (Comment ID): 644962

Concern Statement: Navigation is by far the most cost effective and efficient method of moving products long distances, and it is imperative that USACE support economic growth by having a minimum navigable draft level of nine feet for at least eight months, preferably nine months of each year. There are business opportunities now available with the deepening of the Panama Canal and the availability and reliability of navigation to ship large quantities cost effectively and in a timely manner is very important. Low summer flows and flood events worsened by unreliable releases at Gavins Point can have serious negative impacts on transportation.

Response: The MRRMP-EIS includes a suite of actions intended to preclude jeopardy status of the piping plover, the interior least tern, and the pallid sturgeon, and minimize impacts to human considerations.

The navigation NED analysis has evaluated the impacts of different flow actions under the MRRMP-EIS alternatives on navigation through changes in transportation rate savings per USACE guidance (ER 1105-2-100 Planning Guidance Notebook). Changes in transportation rate savings include any changes in transportation costs associated with shifting modes from water to over land or changes in navigation service levels. The navigation NED evaluation indicates that there would be reductions in transportation rates savings and NED values under Alternatives 2, 4, 5, and 6, and increases under Alternative 3, the preferred alternative.

Representative Quotes (Correspondence ID): 83, 168, 176
Comments (Comment ID): 644755, 627430, 645176

Concern Statement: It is unclear how the navigation results could be the same (in terms of tonnage moved) for both Alternative 3 and 5 when Alternative 5 has a fall release and Alternative 3 has no flow management actions.

Response: The navigation analysis was updated to reflect updated H&H modeling and associated RESSIM data. The navigation analysis assumes that tonnage shifts off of the river to alternate modes when river flows fall below 26,000 cfs. Under the updated evaluation, Alternatives 3 and 5 do not result in the same estimates of tonnage shifting off of the river (please see Section 7.1 of the "Navigation Environmental Consequences Analysis Technical Report").

Representative Quotes (Correspondence ID): 239
Comments (Comment ID): 642687

Concern Statement: Including sand and gravel in both the Navigation section and its own standalone section creates some double counting.

Response: While commercial sand and gravel dredging is evaluated in two sections of the Final EIS, the analyses do not result in double counting. These two sections evaluated different aspects of the sand and gravel industry. The Commercial Sand and Gravel Dredging section (Section 3.11 of the Final EIS) evaluates the impacts of the management plan alternatives on the availability of materials (sediment accumulation rate) that are dredged and commercially sold as sand and gravel. The navigation section evaluated the impacts of the management alternatives on the transport of the sand and gravel resources dredged from the river, specifically how river flows would affect the ability to extract and transport sand and gravel (Section 3.15 of the Final EIS). Because these two sections are evaluating different aspects of the sand and gravel industry it is not double counting the potential impacts.

Concern Statement: The “Navigation Environmental Consequences Analysis Technical Report” has many grammatical and formatting errors.

Response: The “Navigation Environmental Consequences Analysis Technical Report” has been updated to eliminate any grammatical or formatting errors.

Representative Quotes (Correspondence ID): 95
Comments (Comment ID): 636834

Concern Statement: Repeated or extended disruption of Missouri River flows will have impacts on transportation of coal that will impact power generation.

Response: The management plan alternatives are not anticipated to have impacts on the transport of coal on the Missouri River under the preferred alternative. As described in Section 3.0 of the “Navigation Environmental Consequences Analysis Technical Report,” the change in releases from Gavins Point Dam would have minimal impact on service levels and season length under Alternatives 3 and 5 compared to No Action. Changes in service level and season length would be large and adverse under Alternative 2 when low summer flows would be implemented. Alternatives 4 and 6 would result in reduced navigation service, reduced transportation rate savings, and increased repair, replacement, and rehabilitation costs in a number of years over the period of record, although the average annual change in NED values compared to No Action is small (less than 2.5 percent). Aside from Alternative 2, Alternatives 4, 5, and 6 as well as the preferred alternative (Alternative 3) would not result in repeated or extended disruptions to navigation. If flow actions were carried forward, navigators would be given advance notice of the flow change. In addition, there are only very small amounts of coal being transported along the river. Current statistics indicate that there has been less than 5,000 tons of coal (total) moved on the Missouri since 2000; one barge moved in 2008.

AE1600 *Affected Environment: Recreation*

Concern Statement: The recreation Affected Environment characterization of the riverine areas as “low density use” sites, especially in North Dakota, is inaccurate as some locations experience crowded recreation facilities and high watercraft densities.

Response: The description of the riverine areas has been changed in the Final EIS, Recreation Affected Environment (Section 3.15.1) to describe high-density recreation use in the summer, especially in the Bismarck area.

Representative Quotes (Correspondence ID): 239
Comments (Comment ID): 642696

EC1600 *Environmental Consequences: Recreation*

Concern Statement: The recreational analysis contained in the Draft EIS is deficient because it does not consider the numerous recreational vehicle established camp grounds located along the Missouri River.

Response: The recreation valuation in the Final EIS included an evaluation of how the MRRMP/EIS alternatives would affect visitation and the economic values of recreation in the lower river. The operability of boat ramps provides an indication of how recreational access would be affected under the alternatives with the changes in river stages and flows affecting boat ramp operability. In addition, the habitat features in the lower river were assumed to improve the quality of the recreational experience, increasing the consumer surplus (unit day value) per visitor per day, which was included in the recreation NED evaluation.

The baseline visitation was obtained from the Missouri River Public Use Assessment: final Report (Steven Sheriff, Rochelle B. Renken, and Thomas B. Trainman; Missouri Department of Conservation – Resource Science Division; March 15, 2011) that uses a 2004 survey of river users. The accesses and areas included in this survey are shown in Table 1 of the report, which includes campgrounds with river access points. This study focused on estimating visitation at recreation areas, river access points, and places where people could easily reach the Missouri River. The visitation estimates from the River Public Use Assessment have been adjusted (i.e., increased) to reflect current use levels through a proportional increase in population in the counties along the river. All visitors within proximity to habitat areas in the lower river were assumed to benefit from the existence and creation of emergent sandbar, shallow water habitat, and intercept rearing habitat (through a higher consumer surplus value) because of the aesthetic qualities and potential opportunities for more remote and natural recreational experiences with these habitat areas. The recreation evaluation focused on the recreational conditions and attributes that could be affected under the alternatives, such as river stages and habitat areas, and has included RV and other campground visitation in the evaluation.

Comments (Comment ID): 645218

Concern Statement: The economic analysis is deficient because there is no information provided on the impacts to commercial fishing.

Response: The economic analysis is not deficient due to the lack of commercial fishing information. CEQ's NEPA regulations state that data and analyses included in an EIS should be commensurate with the importance of the impact (40 CFR 1502.15). A qualitative discussion of the potential commercial fishing impacts resulting from the alternatives was included in the Fish and Wildlife section (Section 3.5) and the Ecosystem Services section (Section 3.23) of the Final EIS. USACE has determined that the alternatives would have a negligible impact on commercial fisheries and a detailed economic analysis of commercial fishing was not deemed to be warranted.

Representative Quotes (Correspondence ID): 76
Comments (Comment ID): 633560

Concern Statement: Paddlefish snagging recreational activities occur in the river below Gavins Point Dam, which could be adversely impacted by fall releases from the dam reducing snagging opportunities and harvest levels.

Young walleye abundance is highest in Lewis and Clark Lake in the late fall, and fall releases of 60,000 cfs would likely result in entrainment of the walleye. Both spring and fall releases would result in decreased walleye abundance in Lewis and Clark Lake, adversely affecting the fishery.

In Lake Oahe, major flow events result in degraded fishery quality and angler use a few years after their occurrence, resulting in low angler use even at high reservoir elevations. Major flow events have the ability to flush the majority of pelagic prey (rainbow smelt and lake herring) and Chinook salmon through Oahe Dam, resulting in long-term impacts to the fishery.

The need for an immediate source of water to support flow-related management actions could affect the elevation of Lake Francis Case during walleye spawning, thereby reducing the stability and quality of the walleye fishery, which contributes significantly to the recreation industry in South Dakota.

Response: The impacts to recreation described in these comments, including the impacts to the fishery and/or paddlefish from flow events below Gavins Point Dam, in Lake Oahe, Lewis and Clark Lake, and Lake Francis Case, are described qualitatively in the recreation environmental consequences section in the Final EIS (Section 3.16.2).

Representative Quotes (Correspondence ID): 206
Comments (Comment ID): 645786, 645143

Concern Statement: The economic analysis in the EIS should assess the benefits to local and regional economies from the increased recreational opportunities in the lower river as a result of recovery habitat projects, habitat values, and sportfish production.

Response: Regional economic impact analyses that estimate jobs and income from visitor spending only include visitor spending from “non-local” visitors, typically defined as visitors that live more than 50 miles from their homes (the USACE Regional Economic System (RECONS) defines local visitors as visitors from *counties* within 50 miles from a recreation area). In general, most of visitation in the river reaches is associated with residents that live within a couple hours’ drive of the river. For example, the Missouri Public Use Assessment indicates that 75 percent of visitors to the lower river live within 30 miles. As a result, these local visitors are described in the Final EIS as “local” and do not inject outside visitor spending into economies near the river. For example, the visitors are likely coming for the day and packing their food for the trip, having purchased it near their home.

There are events, such as the Missouri River 340, a river race on the Missouri River that spans across the state of Missouri, that are likely to bring in outside visitors, generating tourism revenues for communities near these river races. However, the alternatives are not likely to affect the number of visitors to these events because flow releases would occur in the spring and the fall when most of these events would not occur, and the releases are not high enough to noticeably affect the events. A description of these events was included in the Final EIS (Section 3.16.1, Recreation Affected Environment) and noted that there would be regional economic benefits generated from these events, although there would be minimal or no differences among the alternatives when considering the visitation for these events.

In addition, although there are greater opportunities for low-density dispersed recreation along the river where habitat, especially where early life history habitat, is created, there is not a preponderance of evidence to suggest that the creation of these habitat areas would induce additional visitation to the area (Haller pers. comm. 2016, Kuhlman pers. comm. 2016, Schneider pers. comm. 2016). The habitat features improve the quality of the recreational experience, increasing the consumer surplus value per visitor per day, which was included in the NED evaluation. There was not sufficient support from recreation area managers to increase visitation associated with these habitat areas.

Because most of the visitation is “local,” there would be minimal regional economic effects associated with any changes in visitation in the lower river.

Representative Quotes (Correspondence ID): 242
Comments (Comment ID): 645567

Concern Statement: The EIS fails to account for the positive impacts of increased recreation and visitor spending in the OSE section of Alternative 2 associated with floodplain connectivity and improved ecosystem functioning.

Response: Alternative 2 would result in considerably more acres of shallow water habitat and emergent sandbar habitat, and land acquisition than would occur under Alternative 1. Because most of the visitors are “local” visitors in the river reaches, there is little visitor spending that injects new money to support jobs and income in these regions. In addition, although there are greater opportunities for low-density dispersed recreation along the river where habitat, especially where early life stage habitat is created, there is not a preponderance of evidence to suggest that the creation of these habitat areas would induce additional visitation to the area (Haller pers. comm. 2016, Kuhlman pers. comm. 2016, Schneider pers. comm. 2016). The habitat features improve the quality of the recreational experience, increasing the consumer surplus value per visitor per day, which was included in the NED evaluation. There was not sufficient support from recreation area managers to increase visitation associated with these habitat areas. Because most of the visitation is “local,” there would be minimal regional economic effects associated with any changes in visitation in the lower river and inter-reservoir river reaches.

Representative Quotes (Correspondence ID): 242
Comments (Comment ID): 645507

Concern Statement: There is an error in the NED tables in the recreation section of the EIS (Table 3-200) for Alternatives 2–6; the numbers are off by a factor of 1,000. The text above the table is not consistent with the numbers in the table.

Response: The Final EIS was updated to reflect updated H&H data and associated updated recreation NED benefits (see Section 3.16.2, Recreation Environmental Consequences in the Final EIS). All values were checked for accuracy.

Representative Quotes (Correspondence ID): 197
Comments (Comment ID): 645288

Concern Statement: The recreation evaluation has underestimated visitation in the lower river because it used visitation estimates from 2005, and visitation has considerably increased since then (e.g., Race to the Dome, Missouri Rover 340, Katy Trail Bike Ride, Hartsburg Pumpkin Festival). In addition, the Unit Day Value approach is an antiquated approach that has been criticized in the literature (Ready and Navrud, 2005, Lindsey et al, 2004). A hedonic pricing method is more appropriate approach to estimate recreation the lower river.

Response: The visitation estimates for the lower river relied on a 2011 study with visitation data from 2004-2005. The visitation was updated to 2015 levels based on the percent increase in population in the counties adjacent to the river reaches and reservoirs. The Final EIS includes a description of recreational events, such as Missouri River 340 (a river race on the Missouri River that spans across the state of Missouri), Katy Trail Bike

Ride, Race to the Dome (Section 3.16.1, Recreation Affected Environment). However, it is not likely that the alternatives would affect the visitation at these events.

The Final EIS recreation evaluation was updated to use a hybrid method to estimate the recreation consumer surplus values based on both the unit day value (UDV) and the travel cost method (TCM) approaches. The UDV method of estimating willingness to pay relies on expert and informed opinion to assign relative values to recreation days based on the quality of recreational opportunities supported by individual recreation areas. The TCM is a revealed preference method of economic valuation that deduces willingness to pay through observing human behavior (i.e., the number and trips and costs per trip to a recreation area). The approach to estimate the consumer surplus recreation values uses the UDV, which is based on USACE guidance and site-specific ratings and activities, but also recognizes that the UDV may reflect a relatively lower estimate of the consumer surplus value for a recreation visitor-day. Therefore, the UDV (in 2018\$) was estimated and then proportionally increased based on the difference between the UDV and TCM as estimated in the Recreation Economics Volume 6C of the Master Water Control Manual Missouri River Review and Update (USACE 1994). The "Recreation Environmental Consequences Analysis Technical Report" Section 2.4.3 describes the approaches used to estimate the consumer surplus value of a recreation visitor day.

Representative Quotes (Correspondence ID): 197
Comments (Comment ID): 645287

Concern Statement: The recreation evaluation used the unit day value approach, which uses boating recreation in the general recreation category, and as a result there are lower UDV's for boating visitation. Since most of the boating recreation on the upper five reservoirs are also engaged in fishing, the lower UDV is not appropriate. This simplified UDV approach is acceptable for comparing alternatives, but the RED valuation method based on expenditure data should be used when comparing recreation with other interest categories.

Response: The UDV guidance (USACE 2017) indicates that the general category should comprise activities such as swimming, picnicking, and boating. However, based on professional judgment and a review of other studies (Loomis 2005; USACE 2002), boating on the river and reservoirs was allocated to a specialized recreation category with a relatively higher value per day than the general recreation activities. The recreation NED evaluation was also updated with a hybrid approach to estimate the consumer surplus values for a recreation visitor day using both the Unit Day Value and Travel Cost Method. The method to estimate the consumer surplus recreation values uses both the UDV, which is based on USACE guidance and site-specific ratings and activities, but also recognizes that the UDV may reflect a relatively lower estimate of the consumer surplus value for a recreation visitor-day. Information on the UDV's and TCM values from the TCM study conducted as part of the Master Water Control Manual Missouri River Review and Update (USACE 1994) was used to proportionally increase the UDV's to reflect TCM values. Please see Section 2.4.3 of the "Recreation Environmental Consequences Analysis Technical Report" for additional details.

The NED, RED, and OSE impacts have been evaluated for the recreation evaluation. The NED and RED impacts address different topics. The NED and RED results are not used to compare impacts across interests, but assess the tradeoffs across the alternatives. The NED evaluates benefits and losses on a national level, and the RED analysis evaluates impacts on a regional level. The RED results across interests (or

resource topics) cannot be aggregated or compared because the methods of analysis are different among the interests and topics.

Representative Quotes (Correspondence ID): 206
Comments (Comment ID): 645150

Concern Statement: Water depth alone may not be an accurate predictor of habitat availability, recreational use, and subsequent recreational economic impact. Aquatic wildlife pursued by recreational users will occupy habitats when water depth, velocity, and temperature - along with other factors - are aligned for the target species. Water velocity can also affect habitat occupancy, while temperature will affect fish activity. Additional detail on the assumptions and analysis of recreation impacts for the proposed alternatives would be helpful.

Response: Additional details were added to the Final EIS (Section 3.16.2) to describe how the alternatives could affect aquatic resources and fish. The fish and wildlife analysis modeled the quantity of each habitat type to estimate the effects on fish and wildlife species. Changes in habitat types will benefit some types of species and adversely affect others, so generalizations regarding how fish and wildlife will fare under the alternatives is a complicated evaluation. The relevance of habitat availability varies by species and would require additional research to provide specific details on species impacts, which was not warranted for the Final EIS to assess effects to fish and wildlife. Time and resources did not allow for an analysis of velocity.

Representative Quotes (Correspondence ID): 177
Comments (Comment ID): 644636

Concern Statement: Lower reservoir levels would cause prolonged impacts to the fishery and would take years to recover. The recreation evaluation (p. 3-453) states the reservoirs could be up to 5 feet lower than under Alternative 1, and that impacts would be temporary and would typically dissipate within a year; this is not an accurate statement.

Response: This statement regarding lower reservoir elevations affecting the fishery was clarified in the Final EIS, Recreation Environmental Consequences (Section 3.16.2). The Final EIS states that the decreased lake elevations would be temporary, although in some cases, would remain lower for a number of years. It was also clarified that the fishery impacts and resulting visitation could have prolonged effects from decreased lake elevations.

The effects of the management plan on visitation at the reservoirs is based on regression equations and variables that best predict visitation. For Lake Sakakawea, visitation is best explained by a lagged mid-August water elevation variable and price of gas. The discussion in the Final EIS has been updated to describe the prolonged impacts to the fishery past a year or two.

Representative Quotes (Correspondence ID): 239.
Comments (Comment ID): 642709

Concern Statement: USACE should abide by the moratorium of management actions for least tern and piping plovers within the Bismarck-Mandan stretch, including human restriction measures agreed to by the North Dakota Interagency ESH Team. This stretch of river supports high volumes of recreation, and the management actions would bring unnecessary human/bird conflicts.

Response: USACE will continue to work with the interagency ESH team and continue to avoid constructing habitats in areas that would bring unnecessary human/bird conflicts. Constructing habitat in high human use areas is contrary to the idea of providing functional nesting habitat.

Representative Quotes (Correspondence ID): 239
Comments (Comment ID): 642703

Concern Statement: The ESH creation will affect boat navigation on the Garrison reach, which is heavily used during the summer season (355,000 hours of fishing effort Apr 1 – Oct 31, 2015).

Response: The Final EIS has been updated to describe how ESH creation would affect boating recreation, especially during the summer seasons (Section 3.16.2, Recreation Environmental Consequences of the Final EIS). These impacts would be notably greater under Alternative 2. Siting of the habitat areas would avoid high use areas and additional NEPA studies would accompany the habitat construction projects to further analyze these impacts. In addition, constructing habitat in high human use areas is contrary to the idea of providing functional nesting habitat.

Representative Quotes (Correspondence ID): 239
Comments (Comment ID): 642692

Concern Statement: Drawing down Lake Sakakawea would adversely impact the fishery, recreation, and local economies. The North Dakota Game and Fish Department has considerable research and data that shows that: 1) reservoirs must maintain adequate water levels to provide quality habitat; and 2) water levels must rise during the critical spring spawning and egg incubation period (Fryda et al. 2014, Fryda et al. 2010, Scarnecchia et al. 2008). Any alternatives in the MRRMP-EIS or actions identified in the SAMP that increase the frequency of not meeting these water conditions are detrimental to the fishery and are contrary to the management goals and responsibilities of the North Dakota Game and Fish Department – Fisheries Management Division.

There has been considerable sediment deposited in the upper portions of Lake Sakakawea (USACE 2014), and dewatering this depositional zone under the drawdown of the Lake would not undo decades of sedimentation and restore a naturally functioning river. The headwaters region of Lake Sakakawea that would be dewatered is a critical rearing area for juvenile paddlefish. The Yellowstone/Sakakawea stock of paddlefish is one of the most scientifically understood paddlefish populations in North America, and extensive research has shown good inflows combined with high lake levels are crucial for recruitment for this important paddlefish population (Scarnecchia et al. 2008).

Response: USACE understands that maintaining reservoir elevations and increasing reservoirs elevations in the spring is important to maintain the fishery at the upper three reservoirs. The Human Consideration technical staff has spoken with state biologists several times to discuss these issues and have read the Fisheries Management Plans for the Missouri River System. A fishing success proxy metric was developed, which is described in Section 2.4 of the “Recreation Environmental Consequences Analysis Technical Report,” based on input from fisheries biologists, including Dave Fryda, Chris Longhenry, and Mark Fincel. As described in Section 3.1.2 in the “Recreation Environmental Consequences Analysis Technical Report,” a number of variables were evaluated to assess the best predictors of visitation. The fishing success proxy metric was one of these variables. For Lake Sakakawea, the best predictors of visitation

between 2001 and 2012 was the price of gas and one-year lagged mid-August lake elevations. Additional description was added to the Final EIS of the potential impacts to the fishery if criteria noted in the fisheries management plans are not met. In addition, the Final EIS describes how the low lake elevations in the year and years following spring and fall releases could be detrimental to paddlefish populations in the headwaters of Lake Sakakawea.

Representative Quotes (Correspondence ID): 96, 239

Comments (Comment ID): 640213, 645796, 642843, 642846

Concern Statement: The recreation economic analysis is incomplete because RED analysis was not conducted for Lake Sharpe and the inter-reservoir river reaches. In addition, the recreation NED evaluation is also incomplete because the RED analysis was not undertaken.

Response: The Hydrology and Hydraulics models that estimate the reservoir elevations at Lake Sharpe show that lake elevations would be relatively stable and there would not be any noticeable changes to recreational access. Because lake elevations (and visitation) are not likely to be noticeably affected under the alternatives, a RED evaluation was not conducted for this lake because impacts would be the same across all of the alternatives.

The NED and the RED are separate evaluations; however, both evaluations use the estimates of visitation. The NED evaluation uses visitation to estimate the total economic value of recreation through a consumer surplus approach, while the RED evaluation uses visitation to estimate visitor spending and regional jobs, income, and sales.

Comments (Comment ID): 645289, 645284

AE1700 *Affected Environment: Thermal Power*

Concern Statement: The thermal power affected environment indicates that coal-fired power plants are most economically operated as base-load plants. Although this is the case, these units are increasingly called on for dispatchable generation and have flexibility to operate at different loads as the electric market requires. This type of dispatchable generation that can be provided by coal-fired power plants (and not renewables) should be noted in the affected environment.

Response: USACE agrees with this comment and additional discussion has been incorporated into the Final EIS, Section 3.17.1, Thermal Power Affected Environment, on how coal-fired thermal power plants are increasingly being called on to supply dispatchable generation, with the flexibility to operate at different loads as the electric market requires.

Representative Quotes (Correspondence ID): 167

Comments (Comment ID): 643851

Concern Statement: The thermal power affected environment should note the new nameplate capacity for the Heskett Plant (203 MW).

Response: The thermal power affected environment in the Final EIS (Section 3.17.1) has been updated to note the new nameplate capacity for the Heskett Plant.

Comments (Comment ID): 643856

Concern Statement: The Fort Calhoun nuclear plant has ceased operations and will begin a decommissioning process, which should be noted in the thermal power affected environment.

Response: The thermal power evaluation in the Final EIS has been updated to remove the Fort Calhoun nuclear plant from the analysis (Section 3.17.1).

EC1700 *Environmental Consequences: Thermal Power*

Concern Statement: It is suggested that the habitat areas and IRCs should be placed in areas that would not cause adverse effects to water supply intakes.

Response: The siting of habitat areas considers protective measures around sensitive infrastructure and facilities, such as water supply intakes and thermal power plants. USACE works closely with nearby land and facility-owners to minimize impacts and would conduct site-specific NEPA analyses prior to constructing the habitat. In addition, IRC effects on river flow levels is regarded as incidental; IRC habitat construction may locally decrease the stage slightly due to added conveyance. IRCs would be designed to create effective interception hydraulics, food producing, and foraging habitats on the Lower Missouri River. For these projects to be effective and sustainable, the IRC projects would be designed such that the navigation channel and overall bed and hydrological conditions would largely remain unaffected. Refer to the supporting hydrology and hydraulics technical documents (e.g., HEC-RAS Modeling Alternatives Report) for a thorough description of modeling methodology, assumptions, and limitations.

Comments (Comment ID): 646288

Concern Statement: Low summer flows under alternative 2 have the potential to adversely impact power plants, creating problems with intakes and increasing the risk of failure to comply with temperature discharge limits. The low flow conditions under Alternative 2 have the greatest potential to impact the ability to generate power and would occur during a seasonal period of peak demand.

Response: USACE agrees with this comment, and the thermal power evaluation NED, RED, and OSE evaluation in the Final EIS (Section 3.17.2) and in the accompanying “Thermal Power Environmental Consequences Analysis Technical Report” shows that the low summer flows do have considerable impacts to power generation and dependable capacity, especially during the summer season of peak power demand.

Comments (Comment ID): 645769, 645764, 641000, 641329, 633750

Concern Statement: The thermal power evaluation likely underestimates the adverse impacts to thermal power due to the small number of years analyzed (for operations and river temperatures) and/or due to inappropriate modeling assumptions. The 15-year period of analysis will likely miss periods of refill and other conditions which could cause adverse impacts. The full spring release occurred in 10 of 82 years (as modeled with set release parameters), but not during the 12 years evaluated in the thermal power analysis. The thermal power evaluation should include an 82-year period of analysis.

The analysis also assumes that offset energy is available from the market and that transmission facilities could deliver that replacement energy. In addition, low summer flows under Alternative 2 could lead to problems with system reliability from shutting down thermal power plants. Montana-Dakota Utilities does not agree with the assumption in the thermal power evaluation that renewable electric generation resources would be able to replace the lost capacity of thermal fossil-fired electric generation resource if an alternative results in curtailment or shutdown of the resource. The electric load balancing services from dispatchable fossil-fired electric generating units provide a reliable, low-cost and stable transmission grid that intermittent renewable electric generation resources are not able to provide. Renewable electric generation resources such as hydropower and wind-powered generation resources should not be represented as equals when considering offsets and costs since these resources must be backed up by dispatchable electric generation resources. USACE should also consider transmission grid upgrades when representing the "Other Social Effects" associated with the alternatives.

USACE should also consider the benefits from emissions reductions and use the social cost of carbon when estimating the thermal power economic impacts (Review of Estimates of the Social Cost of Carbon in Executive Order "Promoting Energy Independence and Economic Growth" released on March 28, 2017).

Response: USACE agrees that the 15-year period of analysis for the evaluation was likely missing period of refill, especially because a full or partial release did not occur during the 15-year time period under Alternative 5. The Final EIS has been updated to include an extended period of analysis for the river temperatures (1975-2012, excluding 2011). In addition, the impacts to thermal power intakes (when river stages fall below shut down intake elevations) were evaluated in the Final EIS over the 82-year period of record and presented in the figures that show the annual impacts, Sections 3.1 and 4.0 in the "Thermal Power Environmental Consequences Analysis Technical Report."

Interviews with SPP have been conducted and experts have indicated that it is probable that there would be capacity to replace the reduced load, even during the low summer flow events when the reductions in power generation compared to No Action are the largest. However, there is the possibility under Alternative 2, that there could be more severe impacts, with potential impacts to power availability and electricity reliability. Given this, the evaluation does assume that replacement power would be available from the market (i.e., through MISO or SPP depending on the power plant/utility). The analysis does not specify that renewable sources of energy would be the replacement source, but that the MISO and SPP Regional Transmission Organizations would be able to supply replacement energy (renewable sources are part of the power mix). USACE acknowledges that under certain low water conditions and especially under the low summer flow under Alternative 2, multiple plants could be affected. In addition, the coupled effects of both hydropower and thermal power being impacted simultaneously have been analyzed and included in the Final EIS (See Section 7.0 in the "Thermal Power Environmental Consequences Analysis Technical Report"). Additional details on the risks and uncertainties associated with adverse impacts to thermal power have also been included Final EIS, Section 3.17 and in the "Thermal Power Environmental Consequences Analysis Technical Report," Sections 2.1 and 2.2.

The Final EIS, Section 3.17.2, has been updated to include a quantitative evaluation of the air emissions associated with changes in power generation and an evaluation of the social cost of carbon in the OSE subsections. Additional details on air emissions and

social cost of carbon are provided in the “Thermal Power Environmental Consequences Analysis Technical Report,” Section 6.0.

Comments (Comment ID): 645610, 644092, 644062, 644011, 643846, 643893, 643782, 643893

Concern Statement: The impacts associated with low summer flows under Alternative 2 are underestimated for water intakes, energy generation, and sewer treatment plants and should be re-examined. Further, any regulatory burdens as well as costs to adjust to management actions (i.e., modification of intakes) that would be incurred due to management actions should be identified and estimated prior to implementation through input from the affected industries.

Response: USACE acknowledges that low summer flows under Alternative 2 would adversely affect thermal power plants. This would primarily be a result of higher river temperatures affecting the ability of plants to meet regulatory discharge requirements. When power generation is affected during peak summer and winter seasons, replacement capacity may be needed to provide dependable energy during these peak power seasons. The “Thermal Power Environmental Consequences Analysis Technical Report” describes the capital costs needed to replace lost capacity under the alternatives; Alternative 2 would require both replacement power generation and capacity from reduced power generation and capacity during peak power seasons.

Representative Quotes (Correspondence ID): 228

Comments (Comment ID): 645453

Concern Statement: There are four coal-fired power plants in Iowa that are located near the Missouri River. With low flows and stages in the river, the plants would not have sufficient cooling capacity to operate, which would require owners to generate power from more expensive units or purchase power at wholesale market rates. These plants provide important energy for Iowa industries, businesses, and residential customers, and are critical to the economic well-being of the state.

Response: USACE agrees with the comment. The thermal power evaluation estimates reductions in power generation when river flows and stages fall below the plant's shut down intake elevations. It is assumed in the analysis that power plants would have to buy power at wholesale market rates to replace the reductions in power generation. The OSE evaluation includes an assessment of the impacts of electricity reliability on industries and residential customers.

Representative Quotes (Correspondence ID): 224

Comments (Comment ID): 644394

Concern Statement: Alternative 3 is supported because it provides relatively higher river flows and lower river temperatures, resulting in a cost-effective and reliable supply of power generation from both hydropower and thermal power plants.

Response: USACE has chosen Alternative 3 as the preferred alternative for a number of reasons. The lack of a reoccurring spring pulse under Alternative 3 provides some small increases in NED and RED benefits to thermal power, hydropower, and other resources compared to No Action.

Representative Quotes (Correspondence ID): 224

Comments (Comment ID): 644393

Concern Statement: The Thermal Power section does not address the environmental impacts of a gas turbine replacement alternative from an air and water emissions perspective if it is nuclear power being replaced.

Response: The Final EIS has been updated to include a quantitative evaluation of the air emissions associated with changes in power generation and an evaluation of the social cost of carbon (see Section 3.17.2.1 of the EIS and Section 2.6 in the “Thermal Power Environmental Consequences Analysis Technical Report” for a description of the OSE methodology). The evaluation is plant-specific, and it includes the adverse impacts to air emissions associated with replacement power if a nuclear plant is impacted. Alternative 2 would result in the largest adverse impacts to carbon dioxide and carbon dioxide equivalent emissions compared to other alternatives. Nuclear plants would have similar wastewater discharge requirements as other coal and gas-fired plants; therefore, water emissions associated with replacement power if a nuclear power plant is impacted were not evaluated.

Representative Quotes (Correspondence ID): 107
Comments (Comment ID): 644097

Concern Statement: The impacts to thermal power plants have the potential to be significant to customers, regional energy generation, and system reliability. Shutdown of the power generation in the lower river as stated in Draft EIS could be catastrophic and life-threatening, and the Draft EIS analysis of these potential impacts is inadequate. If the Heskett Plant in the Garrison reach is shut down due to low river flow conditions, this could impact Montana-Dakota's ability to accredit all the Heskett units' output capacity in MISO and possibly impact system reliability in the area. In addition, with low river flows in the Garrison reach that would shut down Heskett Plant, other power plants in this reach would also be at risk of a shutdown, resulting in no generation from multiple facilities at the same time. If this type of event would coincide with a period of high demand, the impact to the grid system could result in significant regional transmission impacts. Further study of the likelihood of this occurrence in consideration of USACE implementation of an alternative should be completed to ensure this scenario does not occur.

Response: USACE agrees that under certain low water conditions and especially under the low summer flow under Alternative 2, multiple plants could be affected. Alternative 4 and 6 would result in some years when river flows would be reduced following the spring releases, which would affect multiple power plants as the commenter indicates. Section 3 of the “Thermal Power Environmental Consequences Analysis Technical Report” provides information on the number of power plants affected by river stages falling below shut down intake elevations and river temperatures increasing above 90 degrees. Additional interviews with SPP have been conducted to better understand how the reductions in power generation under the alternatives would affect customers, regional energy generation, power prices, and electricity reliability. Alternative 2 would result in the potential for significant impacts to wholesale energy prices, capacity and energy values and would increase the risk of an extreme event affecting power availability and electricity reliability when multiple plants would be affected. However, SPP has indicated that even in the worst years, it is probable that SPP would have capacity to replace the reductions in load. The coupled effects of both hydropower and thermal power being impacted simultaneously have also been analyzed and included in the Final EIS Section 3.17.2 and “Thermal Power Environmental Consequences Analysis Technical Report,”

Section 7. USACE has chosen Alternative 3 as the preferred alternative partly because there are no additional adverse impacts to thermal power compared to Alternative 1.

Representative Quotes (Correspondence ID): 107, 167

Comments (Comment ID): 644096, 643975, 643869

Concern Statement: In Section 2.3.1.5.3 of the Mainstem Missouri River Reservoir Simulation Report, there are minimum Garrison releases (9,000 and 10,000 cfs) specified to accommodate water supply, water quality, and irrigation uses in the reach. In addition, the Report states that there may need to be temporary increases above the open-water minimum release rates made to the extent reasonably possible to allow intake owners to take remedial action. These USACE statements show the history of established flow levels considered for operation impacts. USACE should apply a more conservative approach when incorporating minimum daily releases and acknowledge that the modeling in the EIS that predicts impacts has a relatively high degree of uncertainty.

Response: The Master Manual indicates that the water control plan's purpose is to meet water supply requirements to the extent reasonably possible. The minimum Garrison releases in the Master Manual that are considered adequate to meet water intake or water quality requirements are used in the ResSim model. The Master Manual currently specifies a minimum daily average Garrison release of 9,000 cfs to avoid low stages at downstream intakes.

Although USACE can help meet short-term intake requirements (e.g., increasing releases for a short period to ensure an intake can access water), it is the intake owners' responsibility to ensure that their intake is operational under the range of flows specified in the Master Manual. Reductions in flows during drought periods is an important water conservation measure and ensures the reservoir system can be operated for the future benefit of all stakeholders in the basin.

Representative Quotes (Correspondence ID): 167

Comments (Comment ID): 643861

Concern Statement: Thermal power impacts are likely underestimated because of the incomplete period of analysis and the inaccurate assumption of similar hydrology among the alternatives. Alternative 1 is not a proper reference case to which the action alternatives are compared because Alternative 1 does not represent the best available science and has only been minimally implemented. For example, the RED impacts for the action alternatives are only incrementally compared to Alternative 1. In addition, minimal difference between Alternative 1 (with spring pulse) and 3 (without spring pulse) is concerning. A similar concern exists between Alternatives 1 and 6. Each alternative needs to be evaluated based on its own financial impacts.

In addition, Section 3.7, Page 46, 3rd paragraph, last sentence indicates that higher river temperatures are a benefit to thermal power, which is inaccurate.

Response: USACE agrees that the 15-year period of analysis for the evaluation is likely missing a period of refill, particularly because a full or partial release did not occur during the 15-year time period under Alternative 5. The Final EIS has been updated to include an extended period of analysis for the river temperatures (1975-2012, excluding 2011). In addition, the impacts to thermal power intakes (when river stages fall below shut down intake elevations) have been evaluated in the Final EIS over the 82-year period of record and presented where possible.

Section 3.1., Introduction, of the Final EIS describes the modeling approach under No Action and the other alternatives. It should also be noted that Alternative 1 is not a representation of what has occurred in the past, but an estimate of how the System would be operated in the future.

In addition, modeled outputs for the No Action Alternative do not match what actually occurred in the past because of operational differences, river geometry changes, and depletions.

The objective of using these models was to inform decision-makers about trade-offs among the alternatives, comparing to the No Action condition. The models and modeling results used in this effort were reviewed extensively by experts both internal and external to USACE. The limitations and intended uses of the models have been well documented in the EIS and technical reports. USACE believes the models reasonably estimate impacts to resources from the alternatives and meet the objective of informing decision-makers and the public about the impacts of the alternatives.

In addition, the thermal power NED analysis has been updated to display the power generated (and energy values) under each of the alternatives; the Draft EIS estimated the reduction in power generation from ideal conditions with no adverse conditions for all alternatives, including No Action. The Final EIS has been updated to show the total impacts under each of the alternatives over the period of record, the average annual impacts, and the change in impacts from No Action. The “Thermal Power Environmental Consequences Analysis Technical Report” provides additional details on annual impacts.

The error in Section 3.7, Page 46, 3rd paragraph, in the last sentence in the Draft EIS that indicates that higher river temperatures are a benefit has been corrected in the Final EIS. Higher river temperatures, especially during the peak summer season, can cause adverse effects to power plants operations and power generation.

In terms of the differences between Alternatives 3 and 1, the “Thermal Power Environmental Consequences Analysis Technical Report” describes the methodology to assess the impacts to power generations from access to water and river temperatures, and presents the results in Sections 3.1, 3.2, 4.4, 5.4, and 6.4. Alternative 3 would increase average annual power generation by approximately 21,000 MWH in the lower river with the lack of plenary pulse and fewer acres of early life stage habitat constructed in the lower river compared to No Action. Alternative 6 would result in a decrease in power generation of 15,317 MWH on average across the period of analysis.

Comments (Comment ID): 644094, 644086, 644076, 644070, 644055, 644047

Concern Statement: It is concerning that there is not a significant difference between Alternative 1 and Alternatives 3–6, which would indicate errors in the analysis. It is unclear how the alternatives would affect river temperatures; please provide information on how construction of IRC and ESH would cause increases in river temperatures. Please provide information on how USACE determined the difference in temperature impacts of SWH and IRC.

Response: The Final EIS has been updated to extend the period of analysis for the river temperatures (1975-2012). In addition, the impacts to thermal power intakes (when river stages fall below shut down intake elevations) were evaluated in the Final EIS over the

82-year period of record. The extended period of analysis shows in the Final EIS that there are some differences between Alternatives 1 and 3 and 6.

The river temperature modeling is described in the Hydrology and Hydraulics Technical Report: HEC-RAS Water Quality Model, provided as supporting documents for the Final EIS. Changes in channel geometry can affect river temperatures; generally, river temperatures can increase with a wider, shallower channel. The channel geometry is different under Alternatives 1 (SWH), Alternative 2 (more SWH), and Alternatives 3–6 (IRC). The ESH habitat is assumed to not affect the channel geometry because sandbars would be created with sediment from the river, in general, causing no change in the channel geometry and water surface elevations. The channel geometry in the HEC RAS models therefore include differences in the channel from anticipated creation of early life stage habitat (and not ESH habitat). The process to determine the channel geometry under the alternatives is described in the Hydrology and Hydraulics Technical Reports. The channel geometry under Alternatives 3–6 is the same across all four alternatives because the IRC habitat development is the same for these four alternatives.

There is considerably more early life stage habitat developed under Alternative 2 compared to No Action, resulting in a shallower river in some areas of the river causing river temperatures to be slightly higher under Alternative 2 than under No Action during peak summer temperatures. There is slightly less IRC habitat developed under Alternatives 3–6 compared to early life stage habitat developed under No Action, which results in some very small decreases in river temperatures during summer peak temperatures under Alternatives 3–6 relative to No Action. The “Thermal Power Environmental Consequences Analysis Technical Report” Section 3.2 has been updated to provide information on the annual impacts regarding river temperatures: the number of power plants (and units) each year affected by the number of days when river temperatures are above 90 degrees. The Hydrology and Hydraulics Technical Report: HEC RAS Water Quality Model provides additional details on the river temperature modeling.

Representative Quotes (Correspondence ID): 107
Comments (Comment ID): 644093, 644070

Concern Statement: The cumulative or coupled impact of the simultaneous reductions in hydropower and thermal power generation on power markets (prices), energy availability, system reliability, and grid stability is not adequately analyzed in the hydropower and thermal power evaluations. The coupled reductions in power generation could potentially lead to significant impacts of power shortages in the power pools and needs to be analyzed in the Final EIS.

Response: The Final EIS was updated with additional details on the coupled impacts to hydropower and thermal power generation associated with the MRRMP-EIS alternatives, with a focus on the peak season months (July, August, January and February).

Interviews with representatives from SPP have been conducted and experts have indicated that it is probable that there would be capacity to replace the reduced load, even during the low summer flow events when the reductions in power generation compared to No Action are the greatest. However, there is the possibility under Alternative 2, that there could be more severe impacts, with potential impacts to power availability and electricity reliability. USACE feels that the methodology used for the thermal power and hydropower evaluation is sufficient for the comparison across the

alternatives and that additional modeling and analysis would not change the outcome and ranking of the alternatives or the selection of the preferred alternative. Additional details on the risks and uncertainties associated with adverse impacts to thermal power have also been included Final EIS, Section 3.17 and in the “Thermal Power Environmental Consequences Analysis Technical Report,” Sections 2.1 and 2.2.

Each of the alternatives sections under Section 3.17.2 in the Final EIS, Thermal Power Environmental Consequences, includes a description of the coupled impacts and the potential impact to RED effects (market prices, electricity rates, and regional economic conditions) and OSE effects (power availability and reliability, grid stability).

Representative Quotes (Correspondence ID): 107, 134, 172

Comments (Comment ID): 644078, 641814, 644078, 640545, 641814, 640632

Concern Statement: Please clarify the statement in Section 3.4, Page 38, last paragraph of section that indicates there were no difference is flow releases out of Gavins Point Dam for Alternatives 1 and 3.

Response: Alternative 1 includes a reoccurring spring pulse, while Alternative 3 does not include a reoccurring spring pulse; as a result, there are differences in the releases from Gavins Point Dam between these two alternatives. Additional detail was added to the Final EIS in Section 3.17.2.6 that describes the impacts between Alternatives 1 and 3 in the years when there are no differences in the releases from Gavins Point Dam. When the hydrology (releases) from the dam is the same for some years/months for both Alternatives 1 and 3, the only difference between the alternatives is the channel geometry; there are more acres of SWH under Alternative 1 than IRC habitat under Alternative 3. These changes in channel geometry have very small, but measurable impacts on river temperatures, resulting in small impacts to thermal power generation. For example, river flows in the modeled years 1980, 1987, 1988, 1990, and 1991 would be relatively similar for both Alternatives 1 and 3; however, Alternative 3 shows that fewer plants would be impacted by temperature than under Alternative 1 in these years. This is likely attributable to the fewer number of acres of early life stage habitat that would be constructed under Alternative 3 relative to Alternative 1 (see Section 3.2 and Section 4.4 in the “Thermal Power Environmental Consequences Analysis Technical Report”).

Representative Quotes (Correspondence ID): 107

Comments (Comment ID): 644074

Concern Statement: The thermal power evaluation should provide the results of the impacts due to elevation/flow or temperature for each affected power plant. Please provide the number of instances of impacts to power generation from either flow/stage or from river temperature, especially noting river temperatures above 90 degrees. In addition, the tables showing the adverse effects as positive numbers is difficult to understand.

Response: The thermal power NED analysis has been updated to display the power generated (and energy values) under each of the alternatives; the Draft EIS estimated the reduction in power generation from ideal conditions with no adverse conditions for all alternatives, including No Action. The Final EIS has been updated to show the total impacts under each of the alternatives over the period of record, the average annual impacts, and the change in impacts from No Action. The “Thermal Power Environmental Consequences Analysis Technical Report” Section 3.0 has been updated to provide information on the annual impacts regarding river temperatures and river stages: the number of power

plants (and units) each year affected by the number of days when river temperatures are above 90 degrees and below shut down intake elevations. The Hydrology and Hydraulics Technical Report: HEC RAS Water Quality Model provides additional details on the river temperature modeling. The EIS and technical report do not provide results for each of the power plants due to proprietary nature of the information. USACE has made these results available to utilities/plants to show power plant-specific impacts.

Representative Quotes (Correspondence ID): 107
Comments (Comment ID): 644040, 644029, 644021, 643975

Concern Statement: The thermal power evaluation is incomplete because it did not include the potentially significant capital costs to power plants from flow release alternatives that would have to be mitigated. In addition, the thermal power analysis of capacity values incorrectly omits power plant decommissioning costs.

Response: The methodology for the evaluation of thermal power plants includes the capital costs to replace lost dependable capacity, as described in the “Thermal Power Environmental Consequences Analysis Technical Report.” However, as the commenter indicates, these capital costs to replace capacity do not include decommissioning costs. The Final EIS has described the needed replacement capacity under the alternatives. In addition, example decommissioning and dismantlement costs have been added to the Thermal Power Environmental Consequences section in the Final EIS (Section 3.17.2.) and in the “Thermal Power Environmental Consequences Analysis Technical Report” Section 2.4.5. The Thermal Power evaluation in the Final EIS noted that the impacts to capacity values, especially as estimated for Alternative 2, could be underestimated because decommissioning costs are not included in the capacity replacement estimates. These costs were not directly factored into this analysis because of the multiple variables affected decommissioning costs, the uncertainty of the impacts of reduced capacity on the need to decommission the power plants, and because of the need to maintain consistency in the evaluation across power plants and with the hydropower evaluation. USACE feels that the methodology used for the thermal power and hydropower evaluation is sufficient for the comparison across the alternatives and that additional modeling and cost evaluations would not change the outcome and ranking of the alternatives or the selection of the preferred alternative.

Comments (Comment ID): 644036, 644033, 644021

Concern Statement: Please provide additional information on the ERDC HEC-NSM temperature model (where is it published and available; is it calibrated and verified). Please provide information on the differences in temperatures among the alternatives resulting from the ERDC temperature model.

Response: The methodology for the ERDC water quality (river temperature) model is documented in the HEC-RAS Water Quality Model Technical Report and is provided as a supporting document for the Final EIS. The calibration and validation process is included in this technical report. The model has undergone Agency Technical Review and District Quality Control, as well as internal ERDC reviews.

The “Thermal Power Environmental Consequences Analysis Technical Report” Section 3.2 has been updated to provide information on the annual impacts regarding river temperatures: the number of power plants (and units) each year affected by the number of days when river temperatures are above 90 degrees. The Hydrology and Hydraulics

Technical Report: HEC RAS Water Quality Model provides additional details on the river temperature modeling.

Representative Quotes (Correspondence ID): 107
Comments (Comment ID): 644024, 643991

Concern Statement: There is some concern about the channel geometry included in the HEC-RAS model for the channel near the Heskett Plant as the model has not been proven to be accurate (associated river stage) at low flows (those under 15,000 cfs) at Heskett. It appears that the model does not take into account channel changes since the 2012 survey was conducted and does not include Lake Oahe lake effects and channel siltation. Montana-Dakota requests that USACE confirm whether the model corresponds to flow and elevations outside of the 2012 survey timeframe and make model adjustments accordingly to demonstrate accurate model predictions. Additionally, we recommend USACE consider evaluating this for all affected water users.

Montana-Dakota recommends USACE also review the model accuracy to consider the consequences of multiple stations along the Missouri River being affected by low releases. The effect of the loss of generation from multiple facilities in a single period is much more significant than the loss of generation from one facility. Loss of generation from multiple regional or local generation resources may have the potential for a larger impact to transmission grid reliability. This subject requires more than the limited amount of discussion found on page 3-475 of the MRRMP-EIS.

Response: The HEC-RAS model is based on the best available channel survey information and is calibrated to 2012 conditions. Local effects on stage due to temporary changes in river conditions, including ice jams, ice cover, and transient sandbar dynamics, are not included within the HEC-RAS model. These temporary effects often cause river stage changes of several feet. However, for the purposes of alternative comparison, including transient effects is not relevant (e.g., the formation of an ice jam has the same effect on all alternatives). All constructed models were calibrated to the same period through 2012. Calibration accuracy within the Garrison reach varies by location but is generally within 0.5 to 1.0 foot for normal and low flows. Model calibration within the Garrison to Oahe reach is discussed in the supporting documents, HEC-RAS Calibration Report, which is available online (www.moriverrecovery.org). USACE believes that model results are suitable to use for this analysis and to compare results across the alternatives. The Final EIS methodology employs an 82-year period of record with current water development conditions to evaluate differences between alternatives. Use of the extensive 82-year period allows for reasonable alternative impact evaluation for a wide range of flow events.

During the EIS modeling and evaluation process, numerous conversations were conducted with Heskett personnel. The intake elevation shutdown criteria were adjusted during this process as a result. The information used in the Final EIS analysis incorporated input from Heskett personnel.

Representative Quotes (Correspondence ID): 167
Comments (Comment ID): 643858

Concern Statement: The Draft EIS fails to adequately assess the potential for significant operational impacts at Heskett, including limitations in providing fire protection safety for the facility, and shutdowns if there was not sufficient river flow from implementing

Alternatives 2, 4, and 5. It is asserted that USACE assumptions under all alternatives are problematic and further evaluation is warranted.

Response: The Final EIS has been updated to include an extended period of analysis for the river temperatures (1975-2012). In addition, the impacts to thermal power intakes (when river stages fall below shut down intake elevations) were evaluated and updated in the Final EIS. The Thermal Power environmental consequences section was also updated to include a qualitative description of other impacts to power plants when river flows are very low, including fire protection and safety concerns.

The hydrology and hydraulics models and economic approaches have been reviewed internally by USACE experts and through an Independent External Peer Review. USACE and reviewers believe that the models and approaches are sufficient to compare impacts across alternatives. Limitations and assumptions are provided in the Hydrology and Hydraulics Technical Reports and the Environmental Consequences sections of the Human Considerations resource topics.

Representative Quotes (Correspondence ID): 167
Comments (Comment ID): 643839

Concern Statement: The thermal power evaluation assumed there would be a small increase in maintenance costs for cleaning debris and sediment from Missouri River intakes due to increased aggradation and sediment from proposed seasonal flow releases under Alternatives 1, 2, 4, 5, and 6. There are special conditions for MidAmerican facilities in their permits that include restrictions that no work shall occur below the ordinary high watermark from March 1 to June 30 to avoid impacts to pallid sturgeon. The evaluation should include impacts from aggradation from proposed seasonal flow releases, including the potential for derating or shutdown, should significant aggradation occur during the pallid sturgeon protective period identified in the special conditions.

Response: The thermal power section in the Final EIS (Section 3.17.2) was updated to reflect the concerns noted by MidAmerican; the adverse impacts to intakes and power plants from sediment movement and debris could be serious because there are restrictions on when work can occur on intakes (between March 1 and June 30) to avoid impacts to the pallid sturgeon. In addition, USACE works closely with nearby facility owners to minimize impacts from habitat construction and would conduct site-specific NEPA analyses prior to constructing the habitat.

The cumulative impacts section of the Final EIS quantitative precipitation forecast (QPF) Thermal Power Section 3.17.2.12 describes the potential impacts of aggradation and degradation on the alternatives. Potential impacts associated with aggradation on intake maintenance and timing restrictions were described in the cumulative impacts section.

Representative Quotes (Correspondence ID): 164
Comments (Comment ID): 641365

Concern Statement: Alternatives that include flow releases hold promise for creating critical habitat, though the cost is uncertain and unpredictable. However, without extremely cautious planning, once the water is released, there is no assurance that downstream flows can be maintained at power plants and public water intakes later in the year.

Response: USACE agrees that the flow releases will reduce system storage and could result in lower subsequent releases. The 82-year period of record hydrology and hydraulics analysis shows that lower releases compared to No Action do occur in the year or years

following the spring releases or spawning cues, usually in the late fall and winter. These impacts are described in the Final EIS, Thermal Power Environmental Consequences Section 3.17.2.

Representative Quotes (Correspondence ID): 159
Comments (Comment ID): 640997

Concern Statement: Section 3.2.2.8, Page 3-54, 1st partial paragraph indicates that Alternative 2 could result in additional localized dredging to maintain the navigation channel, which in turn could adversely affect water intakes. The costs for power plants and water supply intakes to mitigate these impacts should be included in the evaluation.

Response: Because Alternative 2 would result in considerably more early life stage habitat than under No Action, there could be adverse effects to power plant intakes from sediment and channel changes. However, the siting of habitat areas considers protective measures around sensitive infrastructure and facilities, such as water supply intakes and thermal power plants, and USACE would work closely with nearby facility-owners to minimize impacts. Additionally, site-specific NEPA analyses would be conducted prior to constructing the habitat. Additional information was added to the Final EIS to clarify these considerations (in the alternatives sub-sections under Final EIS Section 3.17.2).

Representative Quotes (Correspondence ID): 107
Comments (Comment ID): 643913

Concern Statement: Average daily flows can be the culmination of large discharge swings within a 24-hour period. USACE should consider the hourly minimum flows (which can be observed at river gages) when evaluating impacts to downstream water users to more accurately reflect increased power plant shutdown occurrences.

Response: In real-time operations, USACE has a standing order that specifies a minimum hourly flow for a set amount of time, which limits the peaking when releases are low. This is done to limit the stage reduction in the river reaches and to reduce impacts to intakes. Using a daily average to estimate impacts to intakes is adequate and sufficient to compare among the alternatives, which all use daily flow reservoir releases.

AE700 *Affected Environment: Water Supply*

Concern Statement: Table 3-229 shows an incorrect number of intakes in Lake Sakakawea and the Garrison Dam to Lake Oahe Reach (Garrison Reach). The Office of the State Engineer water permit database lists 27 commercial/industrial intakes and 15 municipal intakes in Lake Sakakawea and seven commercial/industrial intakes and seven municipal in the Garrison Reach. The Tesoro Refinery in Mandan as well as the numerous other industrial intakes in Lake Sakakawea for oilfield use have not been included.

Response: The project team worked with the State of North Dakota to identify additional intakes not included in the Draft EIS water supply analysis. While additional intakes have been added, there were other cases where an intake may be listed as having a permit but are not currently active or share an intake with another entity. Thus, is the case for the Tesoro Refinery that shares and intake with the City of Mandan. To the best of our

abilities, the project team reviewed and verified information on operating and shut-down elevations for water supply intakes included in the analysis.

Representative Quotes (Correspondence ID): 239
Comments (Comment ID): 642715, 642719

Concern Statement: Content of Table 3-230 is erroneous. The title says the table contains information regarding flows and elevations associated with water supply intakes, however, the table only includes elevations. It is pointless to show intake elevations as they only matter in relationship to the water surface elevation at the intake. Also, providing elevations in the 1988 vertical datum is fine for the river but the reservoir elevations are referenced to the 1929 vertical datum.

Response: Table 3-230 has been removed from Section 3.18.1 as it was determined it did not provide additional information that was helpful for describing the approach used to evaluate the impacts to water supply intakes from the MRRMP alternatives.

Representative Quotes (Correspondence ID): 239
Comments (Comment ID): 642721

Concern Statement: The EIS needs to make the necessary corrections to the affected environment for water supply intakes to properly describe the intake location, elevation, pumping capacity and population served.

Response: The project team reviewed and verified the data and information used to evaluate impacts to water supply access. For public safety reasons, specific information on individual intakes is not included in the affected environment of the water supply section (e.g., identification, location, elevation, and pumping capacity).

Representative Quotes (Correspondence ID): 204
Comments (Comment ID): 644445

EC700 *Environmental Consequences: Water Supply*

Concern Statement: The economic analysis should assume that intakes would need to install permanent low water pumps to adapt to lower water surface elevations and the costs these systems should be considered instead of renting pumps. The costs included in the Draft EIS that only consider the rental of submersible pumps underestimate the impacts. The Draft EIS does not estimate the cost to communities when they lose access to water. A more detailed examination on the economic impacts to the basin of even one day of interruption to residential and industrial water users needs to be conducted. USACE should quantify the impact of communities being without a water supply for a day and include risk assessment in each of the alternatives. The Draft EIS fails to recognize and address Missouri River bed degradation, which is impacting water supply intakes.

Response: The project team conducted additional research on the use of submersible pumps as credible approach to address short-term temporary impacts when water surface elevations fall below operating thresholds. There is evidence that intake managers, both small and large have used the approach, either currently or in the past, to address the type of impacts that are modeled under the MRRMP alternatives. While this approach may not be the one that would be used by water supply managers in all cases, there is enough evidence that it may be one approach that would be considered. Applying this approach for all alternatives provides a way to compare impacts that may occur under

the different alternatives which is the objective of the analysis. While applying other approaches may bring the analysis closer to what may happen under actual conditions, including these other measures would not change the ranking of the alternatives. The project team did not consider community costs associated with the loss of water supply because the use of submersible pumps to address temporary periods when access to water would be curtailed would avoid further costs to communities as loss in water access would be avoided. The project team did not complete a risk assessment of each alternative as it is not warranted for a Programmatic EIS. The Draft EIS and the Final EIS recognize bed degradation and discuss the impacts the MRRMP alternatives are having on this river process. While the MRRMP-EIS does include an evaluation of the potential impacts of bed degradation and aggradation, the Missouri River Bed Degradation Feasibility Study Technical Report, released in May 2017, contains a more detailed evaluation of bed degradation in the lower river.

Comments (Comment ID): 628360, 638468, 643490, 645611, 645636, 638514, 642118

Concern Statement: It does not appear that the Draft EIS is using the most current information on actual operating and shut-down elevations for the Missouri River water supply intakes.

Response: The project team reviewed and verified all the operating and shut-down elevations used in the analysis for water supply intakes and updated where necessary in the Final EIS.

Representative Quotes (Correspondence ID): 122, 233

Comments (Comment ID): 646376, 642832

Concern Statement: Low summer flows have the potential to adversely impact the operation of water supply intakes for municipal, irrigation, and recreation uses in the riverine reach below Gavins Point Dam.

Response: The impacts of low summer flows on water supply intakes were evaluated under Alternative 2 for intakes located below Gavins Point Dam.

Representative Quotes (Correspondence ID): 206

Comments (Comment ID): 645752

Concern Statement: The model cannot identify the shorter periods of time of possible shutdown events for intakes that have continuous operations because the low end of a daily swing may be masked in a daily average flow value.

Response: In real-time operations, USACE has a standing order that specifies a minimum hourly flow for a set amount of time, which limits the peaking when releases are low. This is done to limit the stage reduction in the river reaches and to reduce impacts to intakes. Because of this, using a daily average to estimate impacts to intakes should be adequate.

Representative Quotes (Correspondence ID): 167

Comments (Comment ID): 645750

Concern Statement: Alternative 3 would result in 22 intakes experiencing an average of 14 days below shut down elevations. There is not a single water utility that has enough

storage or access to alternative sources to be able to operate for 14 days without a water supply.

Response: While the analysis does show that water supply intakes would experience days below both operating and shut-down elevations, the number of days would be less under Alternative 3 than they would be under Alternative 1. Implementation of Alternative 3 would represent a slight improvement in conditions for water supply intakes. The impacts under Alternative 1 include 26 intakes experiencing 22.7 days below shut-down elevations on average per day and thus not a result of implementing Alternative 3.

Representative Quotes (Correspondence ID): 122, 228
Comments (Comment ID): 645615, 638494

Concern Statement: The Draft EIS constitutes the first public report documenting that Missouri River basin communities could be in danger of losing their water supply (under Alternative 1). Water supply operations are a mission-critical, non-stop business and it would be unacceptable and irresponsible to wait until water levels are at critical levels and then rent pumps. The Draft EIS wrongly assumes there would be an adequate supply of pumps in the size and quantity needed to operate the 55 intakes on the river. The NED analysis details another incorrect assumption in the Draft EIS, stating that 55 water suppliers could acquire portable pumps for a cost of \$376,000 per year, which is very low and based upon inaccurate facts. USACE's analysis of renting submersible pump costs and sizes are unrealistic for a major utility intake as the KCMO plant operates with a capacity of 400 million gallons per day (MGD) and average production of 100 MGD increasing to over 200 MGD during high temperature dry periods. Bed degradation already requires winter flows much higher than Master Manual flows.

Response: The project team did not estimate the costs (under Alternative 1) to mitigate the impacts associated with bed degradation that is occurring in many parts of the river as this was not the focus of the analysis. Instead, the project employed a methodology that was focused on measuring impacts, specifically management actions that included changes in flows that may impact intakes. For the Final EIS, the project team considered alternative approaches in addition to submersible pumps that may be implemented to mitigate short-term, low flow conditions especially for larger intakes located on the lower river.

Representative Quotes (Correspondence ID): 122, 186, 228
Comments (Comment ID): 645612, 638299, 641537

Concern Statement: Flow requirements which are much higher than the minimums mentioned in Master Manual due to riverbed degradation, especially in the Kansas City, Leavenworth and St. Joseph areas, should be considered. The current assumption regarding the flows in the Draft EIS is not reasonable to correctly estimate the impacts and costs. USACE should reevaluate its approach and model realistic flow requirements to keep water supply intakes in operations at all times.

Response: The Master Manual indicates that the purpose of the water control plan is to meet water supply requirements downstream of the system to the extent reasonably possible. The minimum Gavins Point releases in the Master Manual that are considered adequate to meet water intake or water quality requirements are used in the ResSim model. Although USACE can help meet short-term intake requirements (e.g., increasing releases for a short period to ensure an intake can access water), it is the intake owners' responsibility to ensure that their intake is operational under the range of flows specified

in the Master Manual. Reductions in flows during drought periods is an important water conservation measure and ensures the reservoir system can be operated for the future benefit of all stakeholders in the basin.

Representative Quotes (Correspondence ID): 37, 156, 204
Comments (Comment ID): 644452, 644707, 628461

Concern Statement: USACE needs to identify all potential regulatory burdens in advance of the implementation of any management plan action. In any instance in which the regulatory cost of compliance increases (i.e., modification of intakes), thorough input needs to be gathered from affected industry sectors to ensure that the impact to both utility companies and ratepayers alike remains minimal.

Response: The MRRMP- EIS is a programmatic evaluation that where possible attempted to identify the regulatory and cost implications of certain management actions on water supply intakes. Because the actual location and scope of management actions is not completely known at this time, additional NEPA evaluations will need to be completed to consider more localized impacts once those projects or actions are defined.

Representative Quotes (Correspondence ID): 228
Comments (Comment ID): 645453

Concern Statement: Falling reservoir levels can adversely impact public water supply and irrigation intakes through increased pumping costs and possible exposure of intakes. Public drinking water systems can also face increasing turbidity as well as taste and odor problems due to low reservoir levels. This not only increases the cost of treatment and, ultimately, the cost to the consumer, but also threatens the ability to comply with the Safe Drinking Water Act.

Response: The water supply analysis included in the Draft EIS evaluated the change in pumping costs that could occur with each of the management plan alternatives. The project team has interviewed water quality experts who have indicated that the management plan alternatives are not expected to cause impacts to water quality. Water quality impacts associated with the management actions are further evaluated in Section 3.18.7 of the Final EIS.

Representative Quotes (Correspondence ID): 206
Comments (Comment ID): 645148

Concern Statement: There has been no effort made to evaluate the impacts and cost associated with low summer flows under Alternative 2 on the water supply.

Response: The impacts of low summer flows on water supply intakes were evaluated under Alternative 2 as documented in Section 3.18.2 of the EIS.

Representative Quotes (Correspondence ID): 37, 40, 156, 204, 216, 233
Comments (Comment ID): 644703, 644451, 644449, 643418, 642806, 628465, 628462

Concern Statement: The access to water at lower flows has been exacerbated by 15 feet of channel degradation occurring in reaches near intake structures over the last 15 years. This degradation has resulted in a regionally supported study by USACE, which must be taken into consideration when evaluating flow effects on water intakes in the Kansas City reach.

Response: The feasibility study studying implications of bed degradation in the lower Missouri River was not available during the preparation of the MRRMP Draft EIS but was released in June 2017. The project team reviewed and integrated relevant information from this study into the Final EIS.

Representative Quotes (Correspondence ID): 204
Comments (Comment ID): 644446

Concern Statement: The report is also inconsistent in assessing risk assuming the worst case for flows, but best case for water utility to respond. The costs for the pumps are not accurate, asset life was shown as 10 years which is too long for this type of service under these conditions, it was also not apparent that a reduced wire to water efficiency was taken into account when calculating electrical costs and the cost in the report should be modified to reflect these considerations.

Response: The project team reviewed and verified the assumptions used for the submersible pumps and updated where necessary for the Final EIS.

Representative Quotes (Correspondence ID): 219
Comments (Comment ID): 643486

Concern Statement: The information on the size of pumps and costs necessary to draw water from the river are under estimated. If a water outage would occur, the State regulatory agency will most certainly require a Boil Order to be issued. USACE should consider the power requirements to operate these auxiliary pumps and if there will generators available to supply power.

Response: The size and number of the pumps used in the analysis was tied to the capacity of each intake. The analysis also included power requirements associated with the pumps. The project team determined that other costs (e.g., boil orders, treatment costs, etc.) were not necessary as the use of submersible pumps would avoid these other costs under the alternatives.

Representative Quotes (Correspondence ID): 216
Comments (Comment ID): 643422

Concern Statement: Water utilities will be at risk from low flows during the winter months if high releases are necessary to meet the goals of Alternatives 4, 5, and 6.

Response: The analysis did consider low flow conditions during the winter months on water supply intakes. The results indicated that some of the management plan alternatives did result in impacts to water supply intakes during the winter due to flow actions that would occur earlier in the year or the year before.

Representative Quotes (Correspondence ID): 205, 216, 233
Comments (Comment ID): 643419, 642821, 642121

Concern Statement: The reported NED and RED impacts are grossly under estimated if a water utility is unable to provide water for 14.7 days, let alone one day.

Response: The H&H modeling results shows that on average, 26 of the 59 water supply intakes evaluated would experience 22.7 days below shut-down elevations under Alternative 1. This is the baseline condition and does not represent an impact from the Management Plan Alternatives. The analysis did not try and estimate the costs to mitigate the impacts under Alternative 1 as these impacts would occur with or without the plan. It is likely that

the water supply intakes showing impacts under Alternative 1 would need to be modified to account for these adverse conditions.

Representative Quotes (Correspondence ID): 216, 233
Comments (Comment ID): 643416, 642802

Concern Statement: There appears to be a discrepancy in the comparison of costs across alternatives for the lower and upper basins. Having water surface elevations fall below shut-down elevations is never a small impact, regardless of how large or small the population is that relies on that intake. Characterizing that effect as small in nature makes it sound trivial.

Response: The analysis focused on the costs to mitigate adverse conditions (water surface elevations falling below operating conditions) and treated intakes in the upper and lower basin the same. While the lower basin tends to have larger intakes serving larger populations, the costs are also larger than for smaller intakes that are generally located in the upper basin. The significance of impacts, in part, were based on the magnitude of costs estimated under each of the alternatives (both in absolute and percentage terms).

Representative Quotes (Correspondence ID): 239
Comments (Comment ID): 642737, 642727

Concern Statement: While it is understood that the methodology was chosen to simplify the evaluation, it underestimates and oversimplifies the effect to water supply intakes on reservoirs.

Response: The methodology used for water supply intakes was designed to evaluate the impacts of the management plan alternatives relative to the No Action alternative. The project team believes the approach is reasonable for the objective of evaluating these alternatives. As with any modeling activity, this analysis is a simplification of actual operations and conditions on the reservoirs.

Representative Quotes (Correspondence ID): 239
Comments (Comment ID): 642723

Concern Statement: Because there was no RED analysis to determine the local effect on water supply, the whole evaluation is skewed in favor of the lower basin. For smaller populations, like many of the communities in the upper basin, the cost for modifying an intake is spread out over less people. A RED analysis, or some kind of local analysis, would potentially paint a different picture when it comes to water supply impacts.

Response: A RED analysis focuses on changes in economic conditions (jobs, income, taxes, etc.). A RED analysis specific to water supply would require determining changes in water rates and how those changes in rates would affect household and business spending. Because the changes in water rates were expected to be small, it was not feasible to conduct a RED analysis for water supply. However, the project team did evaluate the costs to mitigate adverse conditions (water surface elevations falling below operating conditions) and treated intakes in the upper and lower basin the same. While the lower basin tends to have larger intakes serving larger populations, the costs are also larger than for smaller intakes that are generally located in the upper basin. The significance of impacts, in part, were based on the magnitude of costs estimated under each of the alternatives (both in absolute and percentage terms).

Representative Quotes (Correspondence ID): 205, 239
Comments (Comment ID): 642713, 642120

Concern Statement: Reduced river flows increase silt content in the water and processing costs. Low flows also may require further modification of each municipality's intake structures.

Response: The project team interviewed water quality experts who indicated that the management plan alternatives are not expected to cause impacts to water quality, including impacts associated with low summer flows. There is no indication that silt levels will increase significantly under the management plan alternatives. The H&H modeling showed several intakes that would experience adverse conditions (water surface elevations below operating conditions) under Alternative 1 (No Action). It is likely that these intakes would require modifications regardless of whether the management plan was implemented. The water supply analysis focused on the impacts that are likely to occur under each of the management plan alternatives relative (or in addition to) those that occur under Alternative 1. Because the impacts under the management actions are smaller in nature to those likely to occur under the No Action Alternative, the project team concluded that intake modification would not be appropriate to mitigate impacts.

Representative Quotes (Correspondence ID): 195
Comments (Comment ID): 642105

Concern Statement: Impacts could occur to intakes and outfall structures on Lake Sakakawea and on the Fort Peck and Garrison reaches of the Missouri River. The EIS needs to address likely pollutant discharges into the Missouri River from mechanical habitat construction.

Response: The water supply analysis included in the Draft EIS evaluated the impacts to water supply intakes on Lake Sakakawea and those located in the Fort Peck to Garrison Reach. In addition, the Draft EIS did evaluate the impacts of mechanical habitat construction. In addition, it is expected that additional analysis would be conducted in site specific NEPA analysis once the actual location of habitat construction is known.

Representative Quotes (Correspondence ID): 96
Comments (Comment ID): 640268

Concern Statement: The Draft EIS concluded that the impacts under the Other Social Effects (OSE) would be negligible based on the assumption that no community would experience an interruption in their service due to the Management Plan. Conclusions based on this false assumption do not capture the full impacts of the alternatives.

Response: The project team believes that the full impacts to water supply intakes have been addressed in the Draft EIS.

Representative Quotes (Correspondence ID): 122
Comments (Comment ID): 638484

Concern Statement: The EIS needs to quantify how many times the water surface elevations fall below operating conditions and during what period time would they occur (e.g., season). The frequency of the occurrences and associated costs should be included in the final report for each alternative.

Response: The project team provided additional results in the "Water Supply Environmental Consequences Analysis Technical Report" that shows the average number of days per season that water surface elevations fall below operating thresholds. Due to privacy

concerns, this information is aggregated across all intakes. Additional information will be made available upon request from individual water supply operators.

Representative Quotes (Correspondence ID): 122
Comments (Comment ID): 638479, 638457

Concern Statement: USACE should complete additional analysis and modeling the pulse that may occur in year nine for the Final EIS.

Response: The one-time spawning cue test (Level 2) release that might be implemented under Alternatives 3, 4, and 5 was not included in the hydrologic modeling for these alternatives because of the uncertainty of the hydrologic conditions that would be present if implemented. Hydrologic modeling for Alternative 6 simulates reoccurring implementation (Level 3) of this spawning cue over the wide range of hydrologic conditions in the POR. Therefore, the impacts from the potential implementation of a one-time spawning cue test release would be bound by the range of impacts described for individual releases under Alternative 6. This modeling is a reasonable representation of the impacts that could occur to water supply under the one-time spawning cue test.

Representative Quotes (Correspondence ID): 122
Comments (Comment ID): 638300

Concern Statement: The flow actions under the alternatives may lead to low reservoir discharge rates that may cause issues for water intake structures, especially in the winter.

Response: The water supply analysis evaluated changes in flows under each of the management plan alternatives. The analysis showed that impacts can occur to water supply intakes, especially during the winter months. These impacts were included in the analysis.

Representative Quotes (Correspondence ID): 204
Comments (Comment ID): 644447

EC1800 *Environmental Consequences: Wastewater Facilities*

Concern Statement: The wastewater evaluation indicates that in North and South Dakota, low-flow conditions do not drive the wastewater discharge effluent limits for wastewater facilities. However, the EIS should consider that reductions in river flows and the flow regime due to adaptive management or the building of new facilities may affect the ability to discharge to the Missouri River in the future.

Response: USACE conducted interviews with the water quality regulators in North Dakota and South Dakota (Haroldson pers. comm. 2015; Spangler pers. comm. 2015) for the wastewater evaluation. The management plan alternatives were described, and the regulators indicated that the flows are sufficient such that technology based effluent standards are always used to assess the wastewater facilities located along the Missouri River, even under the low water months and years. The alternatives are not anticipated to affect lower flows to the extent that they would affect future effluent requirements in the short-term. Major changes in the standards and associated regulations could change effluent discharges through the application of more stringent water-quality based standards; however, any major changes would be speculative. Because the magnitude of flows in the Missouri River in these reaches would remain largely the same under all of the alternatives, and the flows currently necessitate technology-based effluent

standards for wastewater facilities, these facilities were not carried forward in the wastewater evaluation.

Representative Quotes (Correspondence ID): 239
Comments (Comment ID): 642757

Concern Statement: Low summer flows under alternative 2 have the potential to adversely impact sewer treatment plants, creating problems with intakes and increasing the risk of failure to comply with conditions of discharge permits.

Response: USACE agrees that the low summer flows under Alternative 2 would have adverse impacts to power generation and the ability to discharge wastewater from wastewater treatment plants. The low summer flows, as described in Section 3.19.2 in the Wastewater Facilities section of the Final EIS, have the potential to decrease the summer low flow criteria, on which the effluent discharges are regulated, by up to 19 percent, with the potential for large adverse impacts on two wastewater facilities in Missouri. Low summer flows under Alternative 2 also have the potential to affect the ability for power plant to discharge cooling water during the summers, which can affect the ability of the plants to generate power. These impacts are further documented in Sections 3.17.2 and 3.19.2, the Wastewater and Thermal Power Environmental Consequences evaluations, in the Final EIS.

Representative Quotes (Correspondence ID): 27, 65
Comments (Comment ID): 645769, 645764

Concern Statement: There are concerns about how the habitat construction under Alternative 2 could have large adverse impacts on wastewater facilities. In addition, the wastewater evaluation incorrectly assumes that wastewater facilities will be able to make improvements as needed to address management actions such as low flows in the summer. This assumption is not accurate because investment decisions rely on many variables, including funding, other requirements, logistics, and permitting.

Response: The Final EIS describes the pending technology upgrades on two wastewater facilities, which may be able to treat the discharge to meet more stringent wastewater discharge limits anticipated under Alternative 2 due to the low summer flows. In addition, the Final EIS states that there is uncertainty because of the State of Missouri's pending ammonia standards, effects of low flows under Alternative 2 on the actual effluent limits, and the ability of the new technologies to meet these standards and limits. The facilities either have already made the investment decision or are planning to make investments because of the current and future anticipated regulatory environment, funding, and many other variables, as the commenter indicates. Additional details on the factors affecting these investment decisions were added to Section 3.19.2.5 of the Final EIS to clarify the state of the investments.

The mechanical habitat construction under Alternative 2 would have the potential to have negligible to small adverse impacts on wastewater facility outfalls because each habitat site would be designed to avoid or minimize impacts to environmental, cultural, and socioeconomic resources. In addition, a more detailed hydraulic/geomorphic assessment would also be completed during site-specific planning, engineering and design phases to further mitigate impacts associated with these actions on wastewater facilities. With the site-specific planning and sensitive resource restrictions in place, the impacts of the habitat construction management actions on wastewater facility outfalls would be temporary and negligible to small.

Representative Quotes (Correspondence ID): 228
Comments (Comment ID): 645616

Concern Statement: The impacts associated with low summer flows under Alternative 2 are underestimated for water intakes, energy generation, and sewer treatment plants and should be re-examined. Further, any regulatory burdens as well as costs to adjust to management actions (i.e., modification of intakes) that would be incurred due to management actions should be identified and estimated prior to implementation through input gathered from the affected industries.

Response: USACE agrees that the low summer flows under Alternative 2 would have adverse impacts to power generation and the ability to discharge wastewater from wastewater treatment plants. The low summer flows, as described in Section 3.19.2 in the Wastewater Facilities section of the Final EIS, have the potential to decrease the summer low flow criteria, on which the effluent discharges are regulated, by up to 19 percent, with the potential for large adverse impacts on two wastewater facilities in Missouri. Low summer flows under Alternative 2 also have the potential to affect the ability for power plant to discharge cooling water during the summers, which can affect the ability of the plants to generate power. These impacts are further documented in Sections 3.17.2 and 3.19.2, the Wastewater and Thermal Power Environmental Consequences evaluations, in the Final EIS.

Representative Quotes (Correspondence ID): 228
Comments (Comment ID): 645453

Concern Statement: There is concern that the low summer flows under Alternative 2 would be negatively impact the Blue River Wastewater Treatment Plant. This facility is not specifically identified in the wastewater evaluation.

Response: The facility names have been omitted from the evaluation to protect the proprietary nature of the information. There are two facilities located in St. Joseph and Kansas City in Missouri affected under Alternative 2.

Representative Quotes (Correspondence ID): 204
Comments (Comment ID): 644456

EC1900 *Environmental Consequences: Tribal Interests (Other)*

Concern Statement: Tribal water rights will be detrimentally impacted by implementation of the EIS. Concern is expressed about the type of development that would negatively impact water quality and quantity. Plant species, including those of medicinal, spiritual and cultural importance to the Tribes are at high risk due to the proposed development and potential pollution.

Response: Comment noted. Impacts to Tribal resources are acknowledged in Section 3.20 Tribal Interests (Other), Section 3.9 Cultural Resources, and in various other sections of the environmental consequences chapter. The alternatives do not define, regulate, or quantify water rights or any other rights that the Tribes are entitled to by law or treaty. A description of Tribal water rights is provided in Section 6.5.

Representative Quotes (Correspondence ID): 94
Comments (Comment ID): 633679

Concern Statement: The scope of issues discussed in the Draft EIS is too narrow and excludes concerns of importance to the Tribes including (1) plant species of important to Tribes, (2) need for mitigation of impacts, (3) alternatives to avoid jeopardy for the three listed species such as dam removal, and (4) modernization of the Master Manual.

Response: Plant species important to Tribes are specifically covered in Section 3.5 Fish and Wildlife Habitat of the EIS. Mitigation for impacts to Tribal resources including plant species of importance and cultural resources would occur on a site-specific level as necessary during implementation of construction or vegetation management activities. At the programmatic level, no impacts from the proposed alternatives were identified that would trigger the need for mitigation of impacts. In addition, USACE has a Programmatic Agreement in place with several basin Tribes which serves to mitigate impacts from operation of the reservoir system on a programmatic level. USACE feels it has examined a full range of alternatives and has identified an alternative that meets species objectives while minimizing impacts to other river interests. Therefore, a thorough examination of dam removal is not necessary at this point. Broader updates to the Master Manual for purposes other than ESA are outside the scope of this plan.

Representative Quotes (Correspondence ID): 232
Comments (Comment ID): 645478

Concern Statement: The manner in which impacts to Tribes were determined and quantified is not explained in the Draft EIS.

Response: The methodology used for the human considerations is described in detail in Chapter 3 of the Draft EIS and in the HC technical reports. The evaluations of Tribal interests use the same methodologies as the rest of the HC analysis and are disaggregated (to the extent possible) to the Tribe and/or reservation level.

Examples:

1. The Flood Risk Management analysis of Tribal Interests in Section 3.12.2 Environmental Consequences used calculations of agricultural and structural flood risk (in dollars) within reservation boundaries. This analysis was limited to reservations with land that is in the floodplain of the Missouri River Mainstem and that could be affected by differences between the MRRMP alternatives.
2. The Irrigation analysis of Tribal Interests in Section 3.14.2 Environmental Consequences identified the counties that both overlap with reservation boundaries and could have significant differences between the MRRMP alternatives in terms of Irrigation benefits. The "Tribal Interests" subsection of the "Irrigation" section of the Draft EIS directs the reader to the tables showing differences in county-level benefits for those counties. The irrigation analysis could not be disaggregated further than the county level.
3. The Recreation analysis of Tribal Interests in Section 3.16 Environmental Consequences used the results of the recreation analysis at the level of the reservoir and/or river reach. The differences between MRRMP alternatives at the reservoir/reach level provide the best indication of differences in recreation benefits at the reservation level. The recreation analysis could not be disaggregated further than the reservoir/reach level.
4. The Water Supply analysis of Tribal Interests in Section 3.18.2 Environmental Consequences used an inventory of specific intakes that serve Tribal communities, focusing on differences in intake operating cost between the different MRRMP alternatives.

Representative Quotes (Correspondence ID): 232
Comments (Comment ID): 645473

Concern Statement: The manner in which USACE currently operates the dams pursuant to the Master Manual has a significant adverse effect on the Tribes; so the statement on page 3-545 of the Draft EIS indicating that Alternative 1 is not anticipated to have a significant impact on Tribal interests is not valid and should be reassessed.

Response: USACE acknowledges that construction of the Dams adversely impacted Tribes. A detailed examination of the construction and operation of the reservoir system is outside the scope of this effort. This effort is focused on analyzing the impacts of a suite of alternatives designed to benefit endangered species. Impacts to the Tribes from construction and operation of the system are acknowledged in Section 3.20.2.10 Cumulative Impacts.

Representative Quotes (Correspondence ID): 232
Comments (Comment ID): 645469

Concern Statement: The Draft EIS includes an evaluation of impacts on Tribal subsistence activities but contains no baseline data upon which to make this analysis.

Response: The baseline for this analysis would be the No Action alternative, which is a projection of current management for endangered species carried forward into the future. Impacts to Tribal subsistence resulting from implementation of the preferred alternative are presented Section 3.20.2 Environmental Consequences in the EIS.

Representative Quotes (Correspondence ID): 232
Comments (Comment ID): 645458

Concern Statement: The evaluation of potential adverse impacts to plant species used by the Tribes for healing, medicinal and ceremonial purposes is problematic and should be more fully analyzed and disclosed in the Draft EIS.

Response: USACE believes the analysis completed for this effort is sufficient for a programmatic analysis. USACE is committed to continuing to work with the Tribes as site-specific projects are implemented in order to avoid impacts to important Tribal Resources.

AE2200 *Affected Environment: Ecosystem Services*

Concern Statement: The Ecosystem Services section should consider the ecosystem services benefits to: flood risk management from floodplain connection, habitat creation, levee setbacks, and channel widening; water quality and groundwater recharge associated with the federal acquisition of acres for habitat; recreation opportunities; and native fish and wildlife.

Response: The Final EIS was updated to summarize the results from many of the other sections to describe the ecosystem services benefits under the alternatives in the Ecosystem Services Environmental Consequences section.

The following ecosystem services benefits were described in the Final EIS: water regulation and flood attenuation, water quality and water supply, recreation, climate regulations and carbon sequestration, land values, natural resource goods, non-use values, and other cultural services.

Representative Quotes (Correspondence ID): 131
Comments (Comment ID): 640143

EC2200 *Environmental Consequences: Ecosystem Services*

Concern Statement: USACE has not adequately evaluated ecosystem services in the Draft EIS. Ecosystem services that need to be evaluated include flood risk management, recreation, clean water services, and ground water recharge which would all benefit from land acquisition and habitat construction, levee setbacks, wetlands, a wider channel, and floodplain connectivity. Other ecosystem services that should be addressed include savings on flood insurance or FEMA costs; infiltration of rain; greater diversity of plant species; increase in invertebrate diversity; prairie bird nesting; hunting opportunities; buffer crop or buildings from river rises; water quality enhancement, quality of life; natural areas provide relaxation, stress reduction, and thus contribute to the health of a population; interaction with nature which has deep roots in the human psyche; natural lands provide fellowship with others while hiking, boating, camping, fishing, and hunting clubs; a religious interaction with nature and their Creator; and the cultural and religious connections to the river by the Tribes. It is not apparent that these values are captured in other sections of the Draft EIS.

In addition, the Final EIS needs to provide or estimate the values of the ecosystem services. Examples include natural landscapes that also benefit fish and wildlife along the Missouri River and provide aesthetic enjoyment, educational opportunities, and a quality of life component; carbon storage in habitat acreage; and RED values in carbon trading markets.

Response: The Final EIS Ecosystem Services (Section 3.23) was updated to summarize the results from many of the other sections to describe the ecosystem services benefits under the alternatives. For example, the channel widening and IRC habitat provides benefits to flood risk management, especially in the lower reaches of the river. The following ecosystem services benefits were described in the Final EIS in the Ecosystem Services Environmental Consequences section: water regulation and flood attenuation, water quality and water supply, recreation, climate regulation and carbon sequestration, natural resource goods, land values, non-use values, and other cultural services (e.g., quality of life, educational, cultural and spiritual, aesthetic enjoyment, and others).

CEQ's NEPA regulations state that data and analyses included in an EIS should be commensurate with the importance of the impact (40 CFR 1502.15). An evaluation of the potential impacts to the most-affected ecosystem services resulting from the alternatives was included in the Final EIS in the Ecosystem Services section. The alternatives would have a negligible impact on all other ecosystem services and an evaluation was not warranted (for example, for carbon trading values). In some cases, these ecosystem service impacts are quantified (i.e., flood risk management and recreation), and in other cases they are not quantified because of the scale of the analysis needed, the uncertainty in the ecological effect (e.g., varying hydrology under alternatives on ground water recharge and water quality), the programmatic nature of the evaluation, and the anticipated negligible change in the effect among the alternatives.

Representative Quotes (Correspondence ID): 23, 77, 166, 179, 242

Comments (Comment ID): 626661, 645763, 645570, 645232, 644933, 644931

Concern Statement: USACE evaluates many of the ecosystem services in the other sections (e.g., Water Quality, Flood Risk Management). Since the full range of ecosystem benefits is not summarized within the Ecosystem Services section, this separation obfuscates the analysis of ecosystem services. The three ecosystem services that are evaluated in this section are vaguely and qualitatively compared. It is recommended that USACE correct these inconsistencies by giving values to ecosystem services in its own category and presenting the values in a quantified and comparative form to facilitate meaningful comparisons among the alternatives.

Response: The Final EIS was updated to summarize the results from many of the other sections to describe the ecosystem services benefits under the alternatives in the Ecosystem Services Environmental Consequences section. For example, the channel widening and IRC habitat provides benefits to flood risk management, especially in the lower reaches of the river. The following ecosystem services benefits were described in the Final EIS in the Ecosystem Services Environmental Consequences section: flood risk management, water quality and water supply, recreation, climate regulation and carbon sequestration, land values, natural resource goods, non-use values, and other cultural services (e.g., quality of life, educational, cultural and spiritual, aesthetic enjoyment, and others).

CEQ's NEPA regulations state that data and analyses included in an EIS should be commensurate with the importance of the impact (40 CFR 1502.15). An evaluation of the potential impacts to the most-affected ecosystem services resulting from the alternatives was included in the Final EIS in the Ecosystem Services section. The alternatives would have a negligible impact on all other ecosystem services and an evaluation was not warranted (for example, for carbon trading values). In some cases, these ecosystem service impacts are quantified (i.e., flood risk management and recreation), and in other cases they are not quantified because of the scale of the analysis needed, the uncertainty in the ecological effect (e.g., varying hydrology under alternatives on ground water recharge and water quality), the programmatic nature of the evaluation, and the anticipated negligible change in the effect among the alternatives.

Representative Quotes (Correspondence ID): 240

Comments (Comment ID): 644960

Concern Statement: In the ecosystem service evaluation, it is not clear why climate regulation and carbon sequestration are part of the Ecosystem Services section. Climate regulation and carbon sequestration are not directly associated with the river. It is concerning that

none of the ecosystem services were quantified. In addition, the section was not written well.

Response: The Final EIS was updated to summarize the results from many of the other sections to describe the ecosystem services benefits under the alternatives in the Ecosystem Services Environmental Consequences section. The following ecosystem services benefits were described in the Final EIS in the Ecosystem Services Environmental Consequences section: water regulation and flood attenuation, water quality, water supply, recreation, climate regulation and carbon sequestration, land values, natural resource goods, non-use values, and other cultural services (e.g., quality of life, educational, cultural and spiritual, aesthetic enjoyment, and others). An evaluation of the potential impacts to the most-affected ecosystem services resulting from the alternatives was included in the Final EIS in the Ecosystem Services Section 3.23. The alternatives would have a negligible impact on all other ecosystem services and an evaluation was not warranted (for example, for carbon trading values). In some cases, these ecosystem service impacts are quantified (i.e., flood risk management and recreation), and in other cases they are not quantified because of the scale of the analysis needed, the uncertainty in the ecological effect (e.g., varying hydrology under alternatives on ground water recharge and water quality), the programmatic nature of the evaluation, and the anticipated negligible change in the effect among the alternatives.

Air quality, specifically carbon sequestration, was qualitatively evaluated under Ecosystem Services (Section 2.23 in the Final EIS) as it pertains to changes in land ownership and availability of habitat through federal land acquisition and habitat creation because carbon sequestration can potentially affect human well-being. Other human considerations topics, such as thermal power, navigation, and hydropower, evaluated how the alternatives could affect carbon dioxide emissions (and other air emissions) and the social cost of carbon. Please see the Other Social Effects sections of the Final EIS for these resources for additional details (Sections, 3.17, 3.15, and 3.13, respectively).

With respect to the definitions of non-use value, please see Section 3.23.1.8 for additional details. Non-use values, also referred to as “passive use” values, are values that are not associated with actual use, nor are they directly valued in the market. Many natural ecosystems, endangered species, environmental components, and natural amenities are often appreciated by people but may not be directly or indirectly used by humans. Non-use values stem from a desire to preserve or improve a resource (e.g., natural landscape, restored ecosystem, endangered species) as a social or public good (existence value), for future use (option value), or for enjoyment by future generations (bequest value) (Sanders et al. 1990; Brown et al. 2007). Since these values or benefits are not associated with behavior or use, their valuation must rely on people stating their preferences for these preferences, goods, and/or services.

Representative Quotes (Correspondence ID): 179
Comments (Comment ID): 645231

Concern Statement: In the summary and consequence table, ecosystem services are rated the same across all of the alternatives. It is not clear how ecosystem services cannot vary across the alternatives. The units are confusing in the chart. Suggestions for improvement include breaking the chart into smaller sections, and using darker hash marks vs. light dots/line rather than colors.

Response: A qualitative summary of the Ecosystem Services results are provided in the summary and consequence table of the Final EIS. The Final EIS was updated to

summarize the results from each of the other sections to describe the ecosystem services benefits under the alternatives in the Ecosystem Services Environmental Consequences section. The following ecosystem services benefits were described in the Final EIS in the Ecosystem Services Environmental Consequences section: water regulation and flood attenuation, water quality, water supply, recreation, climate regulation and carbon sequestration, natural resource goods, land values, non-use values, and other cultural services (e.g., quality of life, educational, cultural and spiritual, aesthetic enjoyment, and others).

Comments (Comment ID): 645230, 644932

AE2300 ***Affected Environment: Mississippi River***

Concern Statement: The link between the Missouri and Mississippi River should be better studied. Reductions in navigation flow support have cascading impacts, not only to uses on the Missouri River, on the Mississippi River, which is 40 percent of the flow to the Middle Mississippi during normal conditions and peaked at more than 70 percent during the 2012 drought.

Response: Variation in Mississippi River flow for each of the Alternatives could be influenced by a number of downstream factors. All Alternatives were modeled and analyzed with HEC-RAS and ResSim using the same methodology. These models have the capability to accurately assess daily flow change and the comparison between the Alternatives using model output on the Mississippi River is valid. However, the current hydrology, hydraulics, and economic analyses shows the potential for some negative impacts to resources for alternatives that include changes in reservoir flow releases. Additional hydrology and hydraulic analyses would be conducted if adaptive management identifies the need for future flow measures. The level of additional hydrologic analysis will be based on USACE guidance and requirements and will identify the change in reservoir pool probability, reservoir release frequency, river stage-frequency, and river stage-duration.

Comments (Comment ID): 628533, 640951, 644739

Concern Statement: The Draft MRRMP-EIS should state that USACE is not authorized to operate the Mainstem Missouri River for the Mississippi River.

Response: The Final EIS has been updated to include the following information. As required by the Master Manual, USACE operates the Missouri River Mainstem Reservoir System for the Congressionally-authorized purposes within the Missouri River basin. USACE lacks authority to alter the purposes of the System or to modify the regulation of the System under the Master Manual for the central purpose of benefiting the Mississippi River.

Representative Quotes (Correspondence ID): 239

Comments (Comment ID): 642781

Concern Statement: The Draft MRRMP-EIS should include the analysis of water compelled rates in Section 3.24, Mississippi River Impacts.

Response: USACE acknowledges that there could be some adverse impacts in some years to Mississippi River navigation, especially during the fall and winter months under Alternatives 2, 4, and 6. The Final EIS was updated to include a navigation NED

evaluation that assessed the changes in operating costs for navigators for the flow changes under the MRRMP-EIS alternatives. Because of the temporary changes in flows under the action alternative relative to No Action, the changes in costs would be temporary and not likely to affect water compelled rates on the Mississippi River. The changes in river flows would not cause a shift in mode to alternate sources. Therefore, a water-compelled rate study was not deemed necessary.

Comments (Comment ID): 645608

EC2300 *Environmental Consequences: Mississippi River Impacts*

Concern Statement: Low summer flows associated with Alternative 2 will adversely affect navigation flows to the Middle Mississippi River and this economic impact should be addressed in the Draft EIS.

Response: A NED evaluation has been conducted on navigation on the Mississippi River. There are impacts to Middle Mississippi River navigation when river stages fall below 0 at the St. Louis gage. The tonnage impacted and costs associated with reductions in river flows and stages on the Middle Mississippi River are provided in Section 3.24.5.2, Mississippi River, Navigation, Environmental Consequences. USACE acknowledges that the spawning cue releases and low summer flows under Alternative 2 could have impacts to Middle Mississippi River navigation in some years, which have been described in this section.

Representative Quotes (Correspondence ID): 27, 29, 33, 65, 145, 197, 228
Comments (Comment ID): 645621, 626696, 646284, 645265, 646277, 631570, 645765, 626742, 645637, 645623

Concern Statement: There is no mention of the biological resources in the Middle Mississippi River within the Draft EIS.

Response: Impacts to biological resources in the Middle Mississippi are assessed and reported in the Draft EIS beginning on page 3-595 in Section 3.24.3. This section describes the methodology and results of assessing the impacts from alternatives to biological resources in the Middle Mississippi. Although Alternatives 2, 4, 5, and 6 include flow actions, they are not large enough to be measurable beyond what can be described as "small or negligible" in the Middle Mississippi, as reported in the Draft EIS.

Representative Quotes (Correspondence ID): 228
Comments (Comment ID): 645622

Concern Statement: The Draft EIS fails to perform an adequate RED, NED, OSE, and EQ analyses on navigation in the Middle Mississippi River in a similar way as analyzed for the Missouri River. A comprehensive RED analysis for navigation would illustrate the negative impacts of the alternatives on the local and regional economic conditions (jobs, income, revenues). Finally, the failure to perform a comprehensive NED analysis on the impacts to the Mississippi River is also unacceptable given the Mississippi Rivers major contribution to the Nation's economy. By failing to conduct and NED, RED, OSE, and EQ analysis in its modeling, the Draft EIS is significantly understating the economic, environmental, and social impacts of the alternatives on Mississippi River navigation.

Response: A NED evaluation has been conducted on navigation on the Mississippi River with input from industry and the USACE St. Louis District. There are impacts to Middle

Mississippi River navigation when river stages fall below 0 at the St. Louis gage. The tonnage impacted and costs associated with reductions in river flows and stages on the Middle Mississippi River are provided in Section 3.24.5.2, Mississippi River, Navigation, Environmental Consequences. USACE acknowledges that the releases under Alternatives 2, 4, and 6 could have adverse impacts to Middle Mississippi River navigation in some years, which have been described in this section. A RED and OSE evaluation was not conducted as part of the Mississippi River navigation evaluation because changes in river stages would not cause navigation to cease on the Middle Mississippi River such that commodities would need to be shipped by alternate modes. Reduced river flows in a number of years would increase operating costs. In addition, the average annual increase in operating costs would be greatest under Alternative 6, with an increase in NED costs of \$197,000 (0.4 percent). There would be six years over the POR where operating costs would be over \$1 million higher under Alternative 6 compared to No Action, with the average of the 8 worst change years resulting in an increase in operating costs of \$1.8 million compared to No Action. Because the impacts would be temporary and small in most years, a RED and OSE evaluation was not conducted for navigation on the Middle Mississippi River.

Comments (Comment ID): 645620, 645619, 645168, 645167, 644774, 644768, 644767, 644766

Concern Statement: The geographic scope of the Draft EIS does not include the Middle Mississippi River from St. Louis, MO to Cairo, IL. The failure to include the Middle Mississippi River in Draft EIS geographic scope raises questions about USACE's ability to accurately analyze the impacts of the alternatives on the Mississippi River. Pallid sturgeon are using the Middle Mississippi and Draft EIS alternatives should consider the Middle Mississippi and the Missouri Rivers as one and be evaluated as such.

Response: The preferred alternative does include the ability to construct IRC habitat in the very lower portion of the Missouri River. The MRRP ISP has already begun supporting the microchemistry and genetics studies that are the basis for understanding relations with the Mississippi River. Under Big Question 4 on drift dynamics there is a level 1 field study to assess free embryo transport to the Mississippi River. This study will estimate the number and survival of age-0 to juveniles hatched in the Missouri that reach the Mississippi River relative to the number and survival of those that remain in the Missouri River. The SAMP is designed to be flexible and a modified geographic scope for IRC construction could be incorporated into management through the AM process if necessary.

Representative Quotes (Correspondence ID): 228

Comments (Comment ID): 645617

Concern Statement: Under Alternatives 2, 4 and 6, the number of days of normal loading is reduced in these months and navigation restrictions shift to lower (i.e., more restrictive) action level categories with greater impacts. These impacts are substantial enough to not be muted even when evaluating annual impacts.

Response: A NED evaluation has been conducted on navigation on the Mississippi River with input from industry and the USACE St. Louis District. There are impacts to Middle Mississippi River navigation when river stages fall below 0 at the St. Louis gage with impacts to tow configurations and loading of barges. The tonnage impacted and change in operating costs associated with reductions in river flows and stages on the Middle

Mississippi River are estimated in Section 3.24.5.2, Mississippi River, Navigation, Environmental Consequences. USACE acknowledges that the releases under Alternatives 2, 4, and 6 could have adverse impacts to Middle Mississippi River navigation in some years, especially in the fall and winter months, which have been described in this section.

Representative Quotes (Correspondence ID): 197
Comments (Comment ID): 645264

Concern Statement: Increasing flow from Gavins Point Dam while the Mississippi River is experiencing flooding could present a significant threat to public safety. This creates a serious potential for the environmental flow releases on the Missouri River to coincide with regional flooding on the Middle Mississippi River and increase flood risk for communities along the Middle Mississippi River.

Response: Prior to implementing any management action that alters reservoir operations, a comprehensive flood risk evaluation will be conducted per USACE requirements. The level of additional hydrologic analysis will be based on USACE guidance and requirements and will identify the change in reservoir pool probability, reservoir release frequency, river stage-frequency, and river stage-duration. A release would not occur if regional flooding is occurring downstream of Gavins Point Dam. The average annual damages for the Middle Mississippi reach decrease by 0.1 percent or less in Alternatives 2, 3, 5, and 6, and Alternative 4 would result in a 0.1 percent average annual damage increase.

Representative Quotes (Correspondence ID): 168, 197
Comments (Comment ID): 645258, 645182

Concern Statement: The impacts to stage, flood control and navigation on the Middle Mississippi River are significantly understated due to flaws in the hydrological and economic models. The Draft EIS also claims that the spring and fall flow releases in Alternatives 2, 4, 5, and 6 would be partially to largely attenuated by the time they reach Hermann, Missouri. However, the Draft EIS does not provide any detailed analysis as to why this would be the case.

Response: The hydrology and hydraulics models and economic approaches and models have been reviewed internally by USACE experts (Agency Technical Review and District Quality Control) and through an independent external peer review; although more extensive and comprehensive modeling could be undertaken, USACE and reviewers believe that the models and approaches are sufficient to compare impacts across alternatives. Limitations and assumptions are provided in the Hydrology and Hydraulics Technical Reports and the Environmental Consequences sections of the Human Considerations resource topics.

The Missouri River is a dynamic system that is changing constantly. The flow releases from Gavins Point Dam under Alternatives 2, 4, 5, and 6 gradually attenuate in the lower river due to a number of factors, including: (a) the large distance between Gavins Point Dam and the confluence of the Missouri River and the Mississippi River results in flow release peaks spreading out; and (b) rainfall in the watersheds of the numerous tributaries downstream of Gavins Point Dam further spreads out flow release peak (for example, approximately two thirds of the total flow in the Missouri River enters the river downstream of Gavins Point Dam). Attenuation of the flow releases with distance from Gavins Point Dam implies that potential impacts to flooding, navigation, and other

resources also decrease to a similar degree. Residual peaks from flow releases are further attenuated in the Mississippi River from the combined flow. These additional details and description have been added to the Final EIS.

Representative Quotes (Correspondence ID): 168
Comments (Comment ID): 645183, 645181

Concern Statement: The failure to include an independent comprehensive analysis of water compelled-rates in the Draft EIS is inappropriate. By not including this analysis, USACE has understated both the economic benefits of navigation and the impacts of these alternatives on both Missouri and Mississippi River navigation.

Response: USACE acknowledges that there could be some adverse impacts in some years to Mississippi River navigation, especially during the fall and winter months under Alternatives 2, 4, and 6. The Final EIS was updated to include a navigation NED evaluation that assessed the changes in operating costs for navigators for the flow changes under the MRRMP-EIS alternatives. Because of the temporary changes in flows under the action alternative relative to No Action, the changes in costs would be temporary and would not likely affect water compelled rates on the Mississippi River. The changes in river flows would not cause a shift in mode to alternate sources. Therefore, a water-compelled rate study was not deemed necessary.

USACE contracted with the University of Tennessee, Center for Transportation Research to conduct a qualitative assessment of water-compelled rates associated with Missouri River navigation. The University of Tennessee, Center for Transportation Research report provides a historical context of waterway and rail traffic along the Missouri River, noting the relatively recent issues with waterway reliability for navigation; describes past rail regulatory reforms; provides previous estimates of water-compelled effects; and describes the current rail environment that could have implications for these issues. The issues are complicated surrounding water-compelled rates and the dynamic economic conditions and context of the rail industry create uncertainties regarding the effect of Missouri River navigation on railroad pricing. However, the authors conclude that unless expectations regarding the Missouri River's reliability and long-run availability for navigation are reversed, water-compelled railroad rates attributable to Missouri River commercial navigation seem improbable. Further details are discussed in the "Missouri River Water-Compelled Railroad Rates: Review and Qualitative Update" available online (www.moriverrecovery.org).

Representative Quotes (Correspondence ID): 168
Comments (Comment ID): 645170, 645169

Concern Statement: The Draft EIS indicates that the impacts to flood risk management in Section 3.24 were evaluated using two of the four economic account models: NED and OSE. By only using these two accounts to evaluate the impacts to flood risk management, the Draft EIS has omitted key data points resulting in a major understatement of the costs and impacts to Mississippi River flood control interests. A comprehensive RED analysis for the Mississippi River, if done properly, would illustrate the negative impacts of these alternatives on local and regional economic conditions, such as employment, income, sales, sales tax revenue, flood damages, and other potential cost.

Response: There are only very small changes from No Action for flood risk on the Mississippi River. All of the action alternatives 4 show slightly higher flood risk damages, losses and

costs. The magnitude of the change in NED impacts are on the order of 1 percent or less. As a result, a RED analysis for the Missouri River flood risk management evaluation was not warranted for the MRRMP-EIS.

Representative Quotes (Correspondence ID): 168
Comments (Comment ID): 645166

Concern Statement: The impacts relating to the Middle Mississippi are direct and not cumulative. The relationship of the Middle Mississippi and the Missouri River pallid sturgeon is not sufficiently developed in the Draft EIS. Flow and lack thereof affect the performance of the Middle Mississippi and have significant social and economic consequences to the users of the Mississippi River. The failure to directly examine the impact of alternatives to the Middle Mississippi in a direct fashion, and to ignore science indicating the pallid sturgeon's potential gain, requires greater examination of the Middle Mississippi, which should be included in the Draft EIS.

Response: The preferred alternative does include the ability to construct IRC habitat in the very lower portion of the Missouri River. The MRRP ISP has already begun supporting the microchemistry and genetics studies that are the basis for understanding relations with the Mississippi River. Under Big Question 4 on drift dynamics there is a level 1 field study to assess free embryo transport to the Mississippi River. This study will estimate the number and survival of age-0 to juveniles hatched in the Missouri that reach the Mississippi River relative to the number and survival of those that remain in the Missouri River. The SAMP is designed to be flexible and a modified geographic scope for IRC construction could be incorporated into management through the AM process if necessary.

Representative Quotes (Correspondence ID): 222
Comments (Comment ID): 644787

Concern Statement: The implementation of the proposed alternatives, based on the Draft EIS, cause a significant impact to the Middle Mississippi River system located north of Cairo, IL for both flood control and navigation. Any change/alternative producing an induced increase to the water surface elevation on the Middle and Lower Mississippi River is unacceptable.

Response: USACE acknowledges that there could be some adverse impacts in some years to Mississippi River navigation, especially during the fall and winter months under Alternatives 2, 4, and 6. A NED evaluation has been conducted for Mississippi River navigation and additional detail has been added to the Final EIS to describe the impacts under the alternatives. On average, all of the action alternatives would result in changes compared to No Action of less than 0.5 percent.

There are only very small changes from No Action for flood risk on the Mississippi River. All of the action alternatives 4 show slightly higher flood risk damages, losses and costs. The magnitude of the change in NED impacts are on the order of 1 percent or less. As a result, a RED analysis for the Missouri River flood risk management evaluation was not warranted for the MRRMP-EIS.

Representative Quotes (Correspondence ID): 196
Comments (Comment ID): 644145

Concern Statement: When considering NED and associated impacts that USACE should recognize that the waters from the Missouri River do not stop at the arch in St. Louis, nor

does the tonnage coming off of our system, and that while a per ton mile is evaluated, those same tons go all the way to the gulf almost without exception.

Response: The NED evaluation for inland navigation uses transportation rate savings, which estimates the cost savings provided by navigation compared to the next cheapest transportation alternative. Transportation rate savings are calculated using the entirety of the movement, and any movement that touches the Missouri and, for example travel to Gulf Coast, is accounted for in the NED evaluation.

A NED evaluation has been conducted on navigation on the Mississippi River with input from industry and the USACE St. Louis District. There are impacts to Middle Mississippi River navigation when river stages fall below 0 at the St. Louis gage with impacts to tow configurations and loading of barges. The tonnage impacted and change in operating costs associated with reductions in river flows and stages on the Middle Mississippi River are shown in Section 3.24.5.2, Mississippi River, Navigation, Environmental Consequences. There are not anticipated to be navigation NED impacts associated with river flows from the Missouri River below the Ohio River. However, the Middle Mississippi River navigation NED evaluation assumed round-trip mileage for tows to estimate the NED effects.

Representative Quotes (Correspondence ID): 95
Comments (Comment ID): 636843

Concern Statement: The failure to directly examine the impacts of alternatives to the Middle Mississippi River in a direct fashion and to ignore science indicates the pallid sturgeon's potential gain would require greater examination in the Draft EIS.

Response: The preferred alternative does include the ability to construct IRC habitat in the very lower portion of the Missouri River. The MRRP ISP has already begun supporting the microchemistry and genetics studies that are the basis for understanding relations with the Mississippi River. Under Big Question 4 on drift dynamics there is a level 1 field study to assess free embryo transport to the Mississippi River. This study will estimate the number and survival of age-0 to juveniles hatched in the Missouri that reach the Mississippi River relative to the number and survival of those that remain in the Missouri River. The SAMP is designed to be flexible and a modified geographic scope for IRC construction could be incorporated into management through the AM process if necessary.

EC2500 *Environmental Consequences: Climate Change*

Concern Statement: Climate change discussions are required in a Draft EIS, but the predictions used in the analyses are mere speculation.

Response: The climate change analysis included in the Draft EIS is consistent with USACE Engineering and Construction Bulletin (ECB 2016-25) "Guidance for Incorporating Climate Change Impacts to Inland Hydrology in Civil Works Studies, Designs, and Project." The climate change analysis was prepared consistent with CEQ Final Guidance on the Consideration of Greenhouse Gas Emissions and the Effects of Climate Change in NEPA. CEQ withdrew this guidance in April 2017.

Representative Quotes (Correspondence ID): 239

Comments (Comment ID): 642741

Concern Statement: Counter to statements made in the Draft EIS that environmental impacts due to climate change will be equal across alternatives, differences will be experienced because each alternative will cause different levels of fluctuations in Missouri River reservoirs which have detrimental consequences on cultural resources.

Response: USACE concurs that the alternatives would cause different levels of fluctuations in the reservoirs; however, it is assumed that each alternative would be affected by the same climate change scenario.

Representative Quotes (Correspondence ID): 232

Comments (Comment ID): 645442

Concern Statement: Because the consequences of climate change are uncertain and likely will not be distributed across the country equally, USACE should use an increased SCC.

Response: The climate change analysis included in the Draft EIS is consistent with USACE Engineering and Construction Bulletin (ECB 2016-25) "Guidance for Incorporating Climate Change Impacts to Inland Hydrology in Civil Works Studies, Designs, and Project." The climate change analysis was prepared consistent with CEQ Final Guidance on the Consideration of Greenhouse Gas Emissions and the Effects of Climate Change in NEPA. CEQ withdrew this guidance in April 2017.

Representative Quotes (Correspondence ID): 171

Comments (Comment ID): 645198

Concern Statement: USACE should continue to monetize the social costs of carbon by accounting for the global harms caused by climate change.

Response: The global impacts of climate change is beyond the scope of this analysis. The intent of including the social cost of carbon as an aspect of the OSE analysis is to try to estimate and quantify the impact of reduced hydropower production under different alternatives from a national perspective.

Representative Quotes (Correspondence ID): 171

Comments (Comment ID): 645197

Concern Statement: In future impact analyses USACE should use higher underlying estimates for damages from climate change as demonstrated by numerous scientific studies published since 2009.

Response: USACE used the most recent available information from the U.S. Environmental Protection Agency for this analysis at the time.

Representative Quotes (Correspondence ID): 171

Comments (Comment ID): 645196

Concern Statement: Because any agency decision related to climate change will impact future generations in uncertain long-term ways, it was appropriate for USACE to use a lower discount rate for the SCC analysis for the MRRMP-EIS. It should use an even lower discount rates in future analyses.

Response: Comment noted.

Representative Quotes (Correspondence ID): 171

Comments (Comment ID): 645193, 645195, 648194

Concern Statement: Circular A-4 recommends conducting SCC analyses with discount rates of seven percent and three percent; however, additional evidence suggests the lower risk-free discount rate should be less than one percent.

Response: Comment noted.

Representative Quotes (Correspondence ID): 171
Comments (Comment ID): 645192

Concern Statement: USACE should use current dollar values (2016–2017) and not 2007 dollars for determining the value of a metric ton of CO² for the SCC analysis.

Response: The value used for Social Cost of Carbon was obtained from U.S. Environmental Protection Agency sources, which used this price level and the 3 percent discount rate. A 3 percent discount rate was chosen as representative for this estimate because it was closest to the current Federal Interest rate for water resource projects.

Representative Quotes (Correspondence ID): 171
Comments (Comment ID): 645191

Concern Statement: Monetizing the consequences of climate change better informs the public and decision makers. Without context, it is difficult for many decision-makers and the public to access the magnitude and consequences of climate change.

Response: Comment noted.

Representative Quotes (Correspondence ID): 243
Comments (Comment ID): 645116

Concern Statement: USACE should monetize methane and nitrous oxide as well as carbon and adjust for yearly increases in evaluating the potential consequences of climate change.

Response: The climate change analysis included in the Draft EIS is consistent with USACE Engineering and Construction Bulletin (ECB 2016-25) “Guidance for Incorporating Climate Change Impacts to Inland Hydrology in Civil Works Studies, Designs, and Project.” The climate change analysis was prepared consistent with CEQ Final Guidance on the Consideration of Greenhouse Gas Emissions and the Effects of Climate Change in NEPA. CEQ withdrew this guidance in April 2017.

Representative Quotes (Correspondence ID): 244
Comments (Comment ID): 645114

Concern Statement: USACE should move beyond the use of a single estimate to account for the growing social cost of greenhouse gas emissions and acknowledge that increased emissions over time would be more costly. USACE should also acknowledge that there is a range of the social cost of greenhouse gas estimates, including a 95th percentile value that captures uncertainty, risk aversion, and the potential for catastrophic outcomes.

Response: The climate change analysis included in the Draft EIS is consistent with USACE Engineering and Construction Bulletin (ECB 2016-25) “Guidance for Incorporating Climate Change Impacts to Inland Hydrology in Civil Works Studies, Designs, and Project.” The climate change analysis was prepared consistent with CEQ Final Guidance

on the Consideration of Greenhouse Gas Emissions and the Effects of Climate Change in NEPA. CEQ withdrew this guidance in April 2017.

Representative Quotes (Correspondence ID): 244
Comments (Comment ID): 645113

Concern Statement: Small changes in climate variables, if detected and included, in the various models used in the Draft EIS can cause significant differences in model output regarding the consequences of climate change.

Response: Comment noted.

Representative Quotes (Correspondence ID): 166
Comments (Comment ID): 644878

TC1000 *Resources of Concern - Tribal*

Concern Statement: Tribal water rights are being ignored in the Draft MRRMP-EIS. Tribal water rights adjudication and development is quickly advancing. USACE needs to quantify, recognize, and assess these impacts among the alternatives within the Final EIS.

Response: The alternatives do not define, regulate, or quantify water rights or any other rights that the Tribes are entitled to by law or treaty. A description of Tribal water rights is provided in Section 6.5.

Representative Quotes (Correspondence ID): 1, 197, 232
Comments (Comment ID): 645694, 645275

Concern Statement: There should be "rip-rapping" of Tribal areas to preserve 1620 line.

Response: This suggestion is outside the scope of the Management Plan EIS.

Representative Quote: 10
Comments (Comment ID): 627493

Concern Statement: Cultural resources of the Tribes are just as important as the three listed species.

Response: Comment noted. The importance of cultural resources to the Tribes is understood by USACE. Potential cultural resources impacts are examined in-detail in the EIS.

Representative Quotes (Correspondence ID): 10
Comments (Comment ID): 627495

Concern Statement: How will spring/fall pulse impact Tribal intake systems with silt increases and inundation?

Response: The preferred alternative would not include flow options that would increase siltation/inundation of Tribal intakes.

Representative Quotes (Correspondence ID): 10
Comments (Comment ID): 627499

Concern Statement: Concern is expressed over the cultural aspects of scared plants and animals within the habitats that would be impacted by the actions described in the Draft EIS.

Response: Comment noted. Cultural resources impacts and impacts to plants important to Tribes are evaluated in the EIS.

Representative Quotes (Correspondence ID): 57
Comments (Comment ID): 632104

Concern Statement: The quality of water used for water supply should not be affected by increased sediments.

Response: The MRRMP-EIS acknowledges that mechanical construction could temporarily impact water quality by increasing sediment and turbidity. However, any potential water quality impacts will be temporary and localized to the area of construction and a short distance downstream. Given the programmatic nature of this document, specific construction sites are not identified at this time. It should be noted that there would not be any mechanical habitat construction on the reservoirs unless introduced in the future through the adaptive management process. The preferred alternative does not include mechanical habitat construction on the reservoirs. In river reaches, measures will be taken to minimize and prevent construction related impacts and the amount of mechanical construction will be limited to only the amount that is necessary to meet the habitat targets after accounting for available habitat. Adherence to best management practices during construction will minimize or eliminate the risk of unintended water quality effects from discharged sediment and turbidity. Each site-specific construction project will comply with Sections 401, 402, and 404 of the Clean Water Act (CWA) and applicable water quality standards through site-specific analysis and coordination. As discussed in 3.7.2 and 6.3.1., USACE will regulate any discharges of dredge or fill material into waters of the United States, including the Missouri River, pursuant to Section 404 of the CWA. The selection of disposal sites for dredge or fill material will be done in accordance with the Section 404(b)(1) guidelines. Section 401 water quality certifications would be obtained for site-specific management actions, as required, prior to construction. The certification requires a finding by the affected states that the activities permitted would comply with all water quality standards individually or cumulatively over the term of the permit. USACE will conduct testing of material for contaminants prior to using those materials for in-river habitat construction. Furthermore, site-specific NEPA analysis would take place to identify potential issues, including to water quality. As stated in 2.5.1.2, mechanical habitat construction would be guided by a principle of systematic avoidance of potentially sensitive resources (e.g., known locations of protected plant and animal species, natural heritage and cultural resources, public and private infrastructure features) and the de-selection of less suitable project areas.

Representative Quotes (Correspondence ID): 57
Comments (Comment ID): 632121

Concern Statement: The water rights of the Tribe would be detrimentally impacted by the actions discussed in Draft EIS. As a member of the Tribe I am opposed to mechanical construction in the Oahe reservoir. I am also opposed to the type of development which would impact the water quality or quantity. The water rights and water supply issues directly impact me as a Tribal member. The plants, including medicinal and those which

are important to the spiritual and cultural lifeways of my people are at high risk due to the development and resulting pollution along the length of the river.

Response: The MRRMP-EIS acknowledges that mechanical construction could temporarily impact water quality by increasing nutrients, sediment and turbidity, and other pollutants and potentially decreasing dissolved oxygen. However, any potential water quality impacts will be temporary and localized to the area of construction and a short distance downstream. Given the programmatic nature of this document, specific construction sites are not identified at this time. It should be noted that there would not be any mechanical habitat construction on the reservoirs, including Lake Oahe (as stated in 2.5.1.3). Measures will be taken to minimize and prevent these impacts and the amount of mechanical construction will be limited to only the amount that is necessary to meet the habitat targets after accounting for available habitat. Adherence to best management practices during construction will minimize or eliminate the risk of unintended water quality effects from discharged sediment and turbidity, nutrients, and other pollutants. Each site-specific construction project will comply with Sections 401, 402, and 404 of the Clean Water Act (CWA) and applicable water quality standards through site-specific analysis and coordination. As discussed in 3.7.2 and 6.3.1., USACE will regulate any discharges of dredge or fill material into waters of the United States, including the Missouri River, pursuant to Section 404 of the CWA. The selection of disposal sites for dredge or fill material will be done in accordance with the Section 404(b)(1) guidelines. Section 401 water quality certifications would be obtained for site-specific management actions, as required, prior to construction. The certification requires a finding by the affected states that the activities permitted would comply with all water quality standards individually or cumulatively over the term of the permit. USACE will conduct testing of material for contaminants prior to using those materials for in-river habitat construction. Furthermore, site-specific NEPA analysis would take place to identify potential issues, including to water quality. As stated in 2.5.1.2, mechanical habitat construction would be guided by a principle of systematic avoidance of potentially sensitive resources (e.g., known locations of protected plant and animal species, natural heritage and cultural resources, public and private infrastructure features) and the de-selection of less suitable project areas.

Representative Quotes (Correspondence ID): 94
Comments (Comment ID): 633679

Concern Statement: The true environmental impacts on Tribes are not properly considered by USACE in the Draft EIS.

Response: USACE believes the analysis of impacts to Tribal Resources are properly considered given this is a programmatic EIS. A more-detailed examination of impacts would occur on a site-specific basis as projects are implemented.

Representative Quotes (Correspondence ID): 232
Comments (Comment ID): 645423

Concern Statement: The Draft EIS establishes new demands for water, but proposes no changes to current Missouri River operations under the Master Manual in order to fulfill the increased demand. The current operations under the Master Manual degrade Tribal water supplies and impact the Tribe's ability to put water to beneficial use. USACE acknowledges in the Draft EIS that it is Tribal water supplies that will be the source for the downstream fish and wildlife uses (Draft EIS, p. 3-28). The Tribes did not cause the decline of these species, but under the MRRMP, we pay the price of habitat restoration.

Response: The preferred alternative does not include flow options that would increase demands on water.

Representative Quotes (Correspondence ID): 232
Comments (Comment ID): 645425

Concern Statement: The alternatives in the Draft EIS, in combination with the construction of the Mainstem dams, the pattern of water releases pursuant to the Master Manual, and the management of Pick-Sloan project lands for oil and gas pipelines, have a significant, adverse and disproportionate impact on the Indian Nations of the Missouri Basin. Important issues facing the Tribes such as noxious weeds and invasive species on Indian lands caused by USACE Missouri River operations are totally ignored in the Draft EIS.

Response: Comment noted. Cumulative impacts to the Tribes are presented in the Cumulative Impacts analysis and were considered in the decision-making process.

Representative Quotes (Correspondence ID): 232
Comments (Comment ID): 645445

Concern Statement: Council on Environmental Quality regulations require USACE to evaluate the cumulative environmental impact of the proposed action with other past and foreseeable future actions (40 CFR § 1508). The cumulative impact of past actions on the Missouri River, particularly on Tribes needs to be addressed in the Draft EIS cumulative impact assessment.

Response: Comment noted. The cumulative impacts analysis addresses cumulative impacts on the Tribes.

Representative Quotes (Correspondence ID): 232
Comments (Comment ID): 645447

Concern Statement: Cumulative impact to Tribal water supplies in the upper basin, from current USACE operations under the Master Manual, which will be made worse by the proposed alternatives in the Draft EIS need to be considered in the Final EIS.

Response: Comment noted. The cumulative impacts analysis addresses cumulative impacts on the Tribes. The preferred alternative is not anticipated to increase impacts on the Tribes.

Representative Quotes (Correspondence ID): 232
Comments (Comment ID): 645454

Concern Statement: Although USACE mentions the Missouri River Master Manual, the 999 EIS fails to disclose the significant adverse impact of the construction of the dams or the on-going adverse impacts caused by the Master Manual on Indian water.

Response: The EIS baseline is with the dams in place and a hydrologic modeling of social effects of the construction of the dams on Tribes is beyond the scope of this EIS. The cumulative impacts analysis recognizes the effects of dams on the Tribes. Comment noted. Impacts to Tribal resources are acknowledged in the Tribal Resources section, the Cultural Resources section, and in various other sections of the environmental consequences chapter.

Representative Quotes (Correspondence ID): 232
Comments (Comment ID): 645455

Concern Statement: USACE acknowledges that Tribes will incur increased costs to access water in the future, upon implementation of the alternatives in the Draft EIS (Draft EIS, p. 3-28). These cumulative adverse impacts on Tribal economies should be disclosed and evaluated by USACE.

Response: The analysis included in the Draft EIS did consider how costs would change for water supply intakes under each of the Management Plan alternatives. This includes costs associated with Tribal intakes. The results under the alternatives indicate a slight increase in costs under certain alternatives.

Representative Quotes (Correspondence ID): 232
Comments (Comment ID): 645459

Concern Statement: The cumulative impacts summarized in Table 3-1 of the Draft EIS identify oil and gas production as a related cumulative action affecting Tribes. However, the approval of the Dakota Access Pipeline and the Presidential Permit for the Keystone XL Pipeline pose significant environmental risk to the Missouri River, and there is no quantitative analysis of this risk. Table 3-1 simply is not an adequate disclosure of the cumulative impacts of oil and gas pipelines and MRRMP on the Tribes.

Response: The alternatives in the EIS primarily consist of changes in flow operations and construction activities and would not exacerbate the impacts that could be incurred as a result of an oil spill or other pipeline related impact.

Representative Quotes (Correspondence ID): 232
Comments (Comment ID): 645460

Concern Statement: The Draft EIS fails to properly account for the effects of the alternatives on Indian Tribes, and fails to acknowledge the overall disproportionate impact of USACE Missouri River operations on Indian Tribes.

Response: USACE believes the analysis of impacts to Tribal Resources are properly considered given this is a programmatic EIS. A more-detailed examination of impacts would occur on a site-specific basis as projects are implemented. The analysis does not indicate that a disproportionate impact would be incurred by Tribes from implementation of the preferred alternative.

Representative Quotes (Correspondence ID): 232
Comments (Comment ID): 645463

Concern Statement: The general impact analysis on Tribes fails to identify the impact of Pick-Sloan on Indian land and water, the assumptions used in the qualitative analysis are incorrect, and the conclusions in the Draft EIS with respect to Tribal impacts are erroneous.

Response: The EIS baseline is with the dams in place and a hydrologic modeling of social effects of the construction of the dams on Tribes is beyond the scope of this EIS. The cumulative impacts analysis recognizes the effects of dams on the Tribes. Impacts to Tribal resources are acknowledged in the Tribal Resources section, the Cultural Resources section, and in various other sections of the environmental consequences chapter.

Representative Quotes (Correspondence ID): 232
Comments (Comment ID): 645465

Concern Statement: The Human Considerations analysis totally downplays Tribal concerns with the disproportionate and long-term negative impacts suffered by the Tribes. The negative impacts experienced by Tribes far exceeds any negative impacts on non-Indian communities, because USACE located the Mainstem reservoirs in Indian Country.

Response: The EIS baseline is with the dams in place and a hydrologic modeling of social effects of the construction of the dams on Tribes is beyond the scope of this EIS. The cumulative impacts analysis recognizes the effects of dams on the Tribes. Impacts to Tribal resources are acknowledged in the Tribal Resources section, the Cultural Resources section, and in various other sections of the environmental consequences chapter.

Representative Quotes (Correspondence ID): 232
Comments (Comment ID): 645474

Concern Statement: A written submission on Human Considerations of the Standing Rock Sioux Tribe/Rosebud Sioux Tribe/Oglala Sioux Tribe/Flandreau Santee Sioux Tribe, as the Great Plains Tribal Water Alliance, has been totally ignored in the Draft EIS.

Response: This written submission was received and considered in the EIS. The letter emphasized the impacts to Tribes resulting from construction of the Mainstem dams and the 1944 Flood Control Act. The cumulative impacts assessment describes past, present, and reasonably foreseeable impacts to Tribal interests and acknowledges impacts to the Tribes resulting from the Mainstem dams.

Representative Quotes (Correspondence ID): 232
Comments (Comment ID): 645475

Concern Statement: USACE has proven it cannot analyze environmental impacts to the Standing Rock Sioux, much less impacts on our valuable water rights.

Response: Comment noted. USACE disagrees and believes the impacts analysis in the EIS is sufficient for a programmatic EIS and the modeling done for this effort used state of the art methods.

Representative Quotes (Correspondence ID): 232
Comments (Comment ID): 645476

Concern Statement: A full evaluation of the impact of Pick-Sloan on Tribes, and the mitigation of those impacts, remains lacking in the Draft EIS.

Response: The EIS baseline is with the dams in place and a hydrologic modeling of social effects of the construction of the dams on Tribes is beyond the scope of this EIS. The cumulative impacts analysis recognizes the effects of dams on the Tribes. Impacts to Tribal resources are acknowledged in the Tribal Resources section, the Cultural Resources section, and in various other sections of the environmental consequences chapter.

Representative Quotes (Correspondence ID): 232
Comments (Comment ID): 645485

Concern Statement: Use natural processes for habitat restoration whenever possible; protect Tribal cultural and; historic resources; work to compensate Tribes for adverse impacts from the dams; improve communications and relations with Tribes, and discuss in the Draft EIS the threat from oil pipelines.

Response: Comment noted. A variety of actions for restoration were examined in the EIS and their impacts on Tribal resources were examined. Compensation to the Tribes from dam related impacts is beyond the scope of this effort. USACE will continue to seek opportunities to coordinate and consult with the Tribes during program implementation. The impact of oil and gas development is discussed in the cumulative impacts section.

Representative Quotes (Correspondence ID): 180
Comments (Comment ID): 645785

Concern Statement: Although pre-dam conditions are included in the assumptions for river and reservoir simulation models, pre-dam conditions on the Reservations are not taken into account as part of the Tribal interests. The negative impacts to Tribes from construction and operation of the dams are not identified. The costs incurred by the Tribes as a result of the Pick-Sloan program are ignored.

Response: The EIS baseline is with the dams in place and a hydrologic modeling of social effects of the construction of the dams on Tribes is beyond the scope of this EIS. The cumulative impacts analysis recognizes the effects of dams on the Tribes. Impacts to Tribal resources are acknowledged in the Tribal Resources section, the Cultural Resources section, and in various other sections of the environmental consequences chapter.

Representative Quotes (Correspondence ID): 232
Comments (Comment ID): 645917

Concern Statement: The MRRMP will exacerbate negative impacts, by supplying Indian water for habitat recovery.

Response: The preferred alternative would not include flow options that would increase demands on water.

Representative Quotes (Correspondence ID): 232
Comments (Comment ID): 645926

OT1000 *Other AE/EC Resource Topics*

Concern Statement: Dam safety needs to be included as one of the primary risk categories within the Draft EIS.

Response: Under Alternative 3, negligible impacts are expected because of the absence of the spawning cue release of the No Action alternative would have a negligible effect. Minor changes in dam safety risk from releases could occur under Alternatives 2, 4, 5, and 6. Although the EIS indicates that risk increases would be minor, as a precautionary measure and following USACE policy, additional HH analyses will be conducted to quantify risk if AM identifies the need for future flow measures as explained in Section 3.12.2.1 of the Final EIS.

Representative Quotes (Correspondence ID): 166
Comments (Comment ID): 644875

EC2400 *Environmental Consequences: Other Socioeconomic Impacts*

Concern Statement: When managing the Missouri River, it is important that the economic impacts to farmers and communities be considered as well as the risks to human lives.

Response: The Final EIS evaluates the impacts from flooding on crop production, planting and harvest costs, structures, infrastructure, and other property in the floodplain in Section 3.12, Flood Risk Management and Interior Drainage. In addition, this section also includes an evaluation of the populations at risk and critical infrastructure affected under the alternatives.

Representative Quotes (Correspondence ID): 13
Comments (Comment ID): 626258

Concern Statement: The costs of the alternatives, especially Alternative 2, will be considerable. Further analysis needs to be performed on the jobs and economic activity that would be created in the recreation industry as well as on the ecosystem services benefits from the additional habitat created under Alternative 2.

Response: The Ecosystem Services Environmental Consequences section (Section 3.23) of the Final EIS was further updated to describe the ecosystem services benefits under the alternatives. For example, the channel widening and IRC habitat provides benefits to flood risk management, especially in the lower reaches of the river. An evaluation of the potential impacts to the most-affected ecosystem services resulting from the alternatives was included in the Final EIS in the Ecosystem Services section. The following ecosystem services benefits were described in the Final EIS in the Ecosystem Services Environmental Consequences section: flood risk management, water quality and water supply, recreation, climate regulation and carbon sequestration, land values, natural resource goods, non-use values, and other cultural services (e.g., quality of life, educational, cultural and spiritual, aesthetic enjoyment, and others). These ecosystem services impacts are analyzed quantitatively or qualitatively as appropriate for the impact analysis. Jobs and economic activity associated with improved ecosystem services have been estimated where feasible (i.e., reduced agricultural flood damages, recreation visitor spending) in the respective Final EIS sections (Section 3.16, Recreation; Section 3.12, Ecosystem Services).

Representative Quotes (Correspondence ID): 242
Comments (Comment ID): 645506

Concern Statement: Relying on averages over the 82-year period of record does not allow a proper evaluation of the flooding and drought conditions and understates the impacts to navigation and other resources. For example, the drought of the late 1980s impacted the resiliency of the navigation sector.

Response: The technical reports associated with the Final EIS include an annual evaluation of impacts for the human considerations including flood risk management, navigation, hydropower, thermal power, irrigation, recreation, water supply, fish and wildlife habitat, cultural resources, commercial sand and gravel dredging, and land ownership. Charts and graphs were included in the technical reports that show the estimated annual impacts associated with the alternative and the difference in the effect from No Action. Flow releases (i.e., pulses) from Gavins Point Dam would not occur during drought or flooding conditions because of the constraining rules that guide when these releases can occur. In most cases, the action alternatives would not affect these extreme conditions on the river. However, residual effects from previous flow releases (e.g., reduced system storage) can have some impacts on navigation and other resources; these impacts are evaluated in the environmental consequences sections and associated technical reports.

In addition, discussion will be added to the affected environment and environmental consequences sections for navigation on the importance of reliability of the Missouri River to navigation operations. This discussion was added to the navigation environmental consequences section in the EIS.

Representative Quotes (Correspondence ID): 176
Comments (Comment ID): 644751

EC2600 *Environmental Consequences: Other Impacts*

Concern Statement: Flow rates and lake levels should be maintained so that residents will continue to have access to clean drinking water, particularly related to the Cedar-Knox Rural Water Project. Additionally, alternatives should strive to reduce adverse impact on farmland preservation.

Response: Regulation of the Missouri River Mainstem reservoir system is conducted by the Missouri River Basin Water Management office and is based upon the objectives in the Master Manual (USACE 2006). Alternative formulation and the interaction with the Master Manual is described throughout the Draft EIS in multiple sections, primarily within Chapter 2 and 3. Actual real-time regulation of the reservoir system is accomplished using the best information and tools available and is adjusted to respond to changing conditions on the ground with one of the objectives to minimize flooding of agricultural lands within the floodplain and preserve these lands for future use.

Representative Quotes (Correspondence ID): 153, 220
Comments (Comment ID): 637690, 637691, 642151

EC2800 *Environmental Consequences: Cumulative Impacts*

Concern Statement: The loss of aquatic and terrestrial habitat below Sioux City is the most critical component impacting native fish species on the Missouri River.

Response: As discussed in the cumulative impacts section for both pallid sturgeon and fish and wildlife habitat, the loss of habitat has adversely affected the pallid sturgeon specifically, as well as other fish and wildlife.

Representative Quotes (Correspondence ID): 237
Comments (Comment ID): 642884

Concern Statement: A sediment analysis needs to be undertaken for the entire river. At the macro level the study should: (1) document the lack of material in the system and (2) demonstrate the importance of sediment in the effort to preserve the pallid sturgeon.

Response: The necessity of conducting a sediment budget was considered during initial study scoping but determined to be unwarranted for the evaluation of study alternatives. This decision was based on the fact that alternatives will not alter the trapping of sediments within the reservoir system. None of the alternatives include sediment management or measures to pass sediments through the reservoir system to the navigation channel downstream of Gavins Point Dam. In addition, based on the 82-year flow record, the flows in the lower Missouri River and sedimentation processes would continue to be dominated by natural reservoir release events (2011, 1997) and significant tributary inflow events (1993). Analysis was performed with a "Year 15" designation that included modeling of conditions 15 years in the future. While not intended to represent detailed

estimates of future reservoir and channel conditions, the results do provide an alternative comparison methodology. Comparison of results determined only minor changes between alternatives. Comparison of alternatives does not indicate a significant difference in downstream sediment loading between alternatives.

Representative Quotes (Correspondence ID): 34
Comments (Comment ID): 628337

Concern Statement: Models used to evaluate river conditions within the Draft EIS do not account for actions that may be taken to address bed degradation. Actual water releases should be used for the baseline analysis.

Response: Actions to address bed degradation are outside the scope of the analysis which is focused on management actions to benefit endangered species. It is not clear that bed degradation is a limiting factor to pallid sturgeon recruitment.

Representative Quotes (Correspondence ID): 122
Comments (Comment ID): 646375

Concern Statement: Ongoing bed degradation should be factored into the Draft EIS impact analysis because river bed degrades additional flow releases to meet authorized needs. The creation of the self-scouring channel has promoted the degradation of the river bottom and caused water to recede from the previously connected backwaters. The nearly completed Missouri River bed degradation study needs to be factored into the evaluation.

Response: While aggradation and degradation processes are known to be occurring within the basin, those processes will continue regardless of the implementation of any Alternative. USACE discusses these processes within multiple sections of the Draft EIS. Based on modeling results, the assumption is that future bed change affects all project alternatives to a sufficiently similar level such that Alternatives can be adequately compared.

Additional flow releases to compensate for bed degradation is not mandated in the Master Manual and has not been included in the alternatives modeling or results.

The Missouri River Bed Degradation Feasibility Study answers the fundamentally different question of what measures could be cost-effectively employed to minimize bed degradation damages from St. Joseph, MO to Waverly, MO. It does not test the Missouri River Management Plan Alternatives.

Representative Quotes (Correspondence ID): 73, 122, 131, 205, 207, 216, 233
Comments (Comment ID): 642834, 635364, 635359, 642123, 643517, 646276, 640161, 645862, 638298

Concern Statement: Low summer flows under Alternative 2 would have a long-term negative cumulative impact on the reliability of Missouri River navigation and would cause shippers to seek other modes of shipping merchandise.

Response: The navigation analysis evaluated the impacts of low summer flows, a management action of Alternative 2, in Section 3.15. In addition, the cumulative impact analysis considered the impacts of low summer flows in addition to past, present and future actions on navigation. In both sections the analysis indicated that navigation would be negatively impacted by low summer flows. While the analysis did not specifically consider the effects on reliability of the river, additional discussion will be added to the Final EIS that addresses this issue.

Representative Quotes (Correspondence ID): 228
Comments (Comment ID): 645911

Concern Statement: The Draft EIS cumulative impact analysis should be amended to bring the focus of all impacts together through more extensive modeling and analysis, including studies of interior drainage.

Response: As defined by NEPA, cumulative impacts are the impacts on the environment that result from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions regardless of what agency or person undertakes the actions. The methodology used for assessing cumulative impacts in this EIS is described in Section 3.1.3. The analysis focuses on each specific resource that could be impacted rather than examining impacts to multiple resources collectively. The EIS provides an exhaustive assessment of impacts on “human considerations” (i.e., the economic, cultural and social values of the system). Additionally, the analysis evaluates the impacts, when possible and appropriate, in terms of the four USACE analysis accounts: national economic development, regional economic development, environmental quality, and other social effects. The robust programmatic analysis provides the public and decision-makers with the necessary information and analysis to understand the type, intensity, and duration of expected impacts. USACE agrees that a statement should be included in the Final EIS that conveys to readers that impacts from one resource could affect others; however, additional extensive economic modeling is not warranted.

Representative Quotes (Correspondence ID): 228
Comments (Comment ID): 645873

Concern Statement: The Draft EIS representation of land use impacts is inaccurate, incomplete and unworthy of the hard work and sincere effort that stakeholders have put forth to recover the species.

Response: USACE disagrees that the land use analysis is inadequate. The analysis focuses on agriculture, the dominant land use in the study area and land acquisition based on the federal government acquiring lands to construct pallid sturgeon early life stage habitat. The analysis examines the impacts using the regional economic development and other social effects accounts. The analysis describes the expected effects from land acquisition related to job losses and property taxes, among other factors. When analyzing the cumulative impacts, it is important to accurately describe the context of the expected impacts. Additionally, including the other actions that could impact land use, especially agriculture, is important in understanding the contribution of impacts from the alternatives when considering other actions. The analysis accurately describes other actions that affect agriculture beyond those impacts expected from the proposed alternatives. The impacts from the proposed alternatives are limited to land acquisition and require willing sellers. The analysis accurately describes the magnitudes of these impacts in relation to other cumulative actions that affect land use and agriculture.

Representative Quotes (Correspondence ID): 228
Comments (Comment ID): 645511

Concern Statement: The cumulative impact analysis should include USACE proposed rulemaking on Use of USACE Reservoir Projects for Domestic, Municipal and Industrial Water Supply. In particular, the impact on Tribal economics should be evaluated.

Response: Given that it is a proposed rule and not final, the analysis cannot be explicit in terms of expected impacts until a final rule is issued.

Representative Quotes (Correspondence ID): 232
Comments (Comment ID): 645461

Concern Statement: Emerging risks to pallid sturgeon recovery associated with Zebra Mussels and other ANS should be evaluated. These risks include modification to substrate, changes to ecological trophic status and the addition of various chemicals into the riverine system to control ANS.

Response: USACE has added discussion of this topic in the pallid sturgeon cumulative impact section.

Representative Quotes (Correspondence ID): 239
Comments (Comment ID): 645404

Concern Statement: The cumulative impacts analysis for water quality should include the effects of oil and gas development along North Dakota's portion of the Lower Yellowstone River and Missouri River.

Response: Information is included in Section 3.7.2.12 that describes the cumulative impacts to water quality from oil and gas development based upon available information related to these impacts.

Representative Quotes (Correspondence ID): 238
Comments (Comment ID): 645347

Concern Statement: The Draft EIS cumulative impact analysis does not adequately address the effects from groundwater use, oil and gas production and grazing. USACE should (1) assess the potential impacts of oil spills on pallid sturgeon survival, (2) provide evidence that pallid sturgeon survival is not impacted by surface water-groundwater interactions, (3) that snag removal does not impact either the pallid sturgeon or their prey species, and (4) evaluate the impacts of animal grazing in the floodplain.

Response: If hypotheses related to impacts from groundwater use, oil and gas production, or grazing are identified and prioritized through the AM process, USACE may consider addressing them through research or monitoring since there could be relevance to the effectiveness of planned or ongoing actions and in the interpretations of pallid sturgeon responses to those actions.

Representative Quotes (Correspondence ID): 238
Comments (Comment ID): 645345

Concern Statement: USACE should re-examine the cumulative impacts of the watershed use on the pallid sturgeon as too much emphasis is placed on navigation.

Response: Modification of the Missouri River to serve authorized purposes such as Navigation are considered in the cumulative impacts analysis.

Representative Quotes (Correspondence ID): 238
Comments (Comment ID): 645344

Concern Statement: Water depletion and water allocations are topics that should be considered as a reasonably foreseeable action to be evaluated as part of the cumulative impact analysis.

Response: The ResSim model accounts for current basin conditions for the entire period-of-record. This includes depletions representative of current basin conditions at the time of the analyses provided by the U.S. Bureau of Reclamation.

Draft surplus water reports were completed on each of the Mainstem reservoirs to try to identify the possible use of surplus water beyond that is currently being used (new agreements). Based on that analysis, future withdrawals are not expected to be significant given the large amount of storage and available flow. The reports tried to identify enough surplus such that we would not need another Surplus Report for a while. The purpose was not to make a prediction on the amount of water withdrawals or the timing of when those withdrawals would come online. Of the 282,917 ac-ft identified as available for use under the Surplus authority on the Missouri Mainstem, only 33,792 (or 12 percent) has been requested. Further use beyond what has been requested is not considered a foreseeable action.

In addition, USACE is not currently moving forward with a permanent reallocation study, and if it did, it would likely overlap with identified water supply under the Surplus authority. USACE is not aware of any large future changes in the number of depletions related to water supply, especially since oil and gas exploration has slowed. There are not any reasonably foreseeable actions identified that have not been evaluated as part of the EIS.

Representative Quotes (Correspondence ID): 197
Comments (Comment ID): 645277, 645276, 645274, 645272

Concern Statement: The text in Draft EIS (Section 3.3.2.11) dealing with the topic of fish stocking and river system alternation should be removed because the claims are unsubstantiated and other scientific information disagrees with stated conclusions.

Response: The referenced statement was removed from the Final EIS.

Representative Quotes (Correspondence ID): 206
Comments (Comment ID): 645149

Concern Statement: The economic effect of MRRP annual expenditures should be factored into the cumulative impact analysis.

Response: The economic impact of program expenditures associated with the MRRP are evaluated under the RED analysis. This includes an analysis of current program expenditures under Alternative 1 and the expenditures that would be expected to occur under each of the management plan alternatives over the next 15 years. The project team believes this analysis meets the requirements of NEPA.

Representative Quotes (Correspondence ID): 222
Comments (Comment ID): 644826

Concern Statement: Past actions and activities on the Missouri River should be considered in the evaluation of cumulative impacts of fish habitat along the Iowa border.

Response: The cumulative impacts analysis includes past, present, and reasonably foreseeable actions such as construction and maintenance of the Bank Stabilization and Navigation Project.

Representative Quotes (Correspondence ID): 190
Comments (Comment ID): 641592

Concern Statement: Prior actions on the river have had long-term negative impact on the three listed species.

Response: USACE concurs; the impacts of past Missouri River actions on the three species of concern are documented in Sections 1.3.1 Pallid Sturgeon and 1.3.2 Interior Least Tern and Piping Plover and further detailed in Sections 3.3.1 Pallid Sturgeon Affected Environment and 3.4.1 Piping Plover and Least Tern Affected Environment.

Representative Quotes (Correspondence ID): 190
Comments (Comment ID): 641581

Concern Statement: USACE should measure the effects of ESH mechanical construction over the life of the MRRP and include this as part of the cumulative impact analysis.

Response: Based on past experience, impacts from mechanical ESH construction are temporary construction related impacts. These impacts are considered in the EIS.

Comments (Comment ID): 640159

AM1000 *Adaptive Management*

Concern Statement: What is the process for demonstrating that the spring rise is actually beneficial to listed species?

Response: The process, described in detail in Section 4.2 of the SAMP, can be summarized as follows:

1. conduct 9 years of monitoring of actual flows and pallid sturgeon responses (movement, aggregation, spawning, reproduction) to test alternative hypotheses concerning the influence of spring flows;
2. at the end of that 9-year period, draw conclusions regarding the need for a managed release of spawning flows, using the evidentiary framework in Table 48 of the Draft SAMP;
3. if it were concluded from the evidentiary framework that managed spawning flows should be implemented, conduct one Level 2 Test of such flows; and
4. based on the results of that test, determine if it would be beneficial to implement further spawning flows.

Representative Quotes (Correspondence ID): 15
Comments (Comment ID): 626301

Concern Statement: Adaptive management decisions regarding proposed actions or modifications of existing actions that are outside those approved under the MRRMP-EIS ROD must undergo additional NEPA review, including public review.

Response: The processes required for different types of AM decisions are described in Chapter 2 of the SAMP and Chapters 2 and 4 of the EIS.

Representative Quotes (Correspondence ID): 33, 98, 145
Comments (Comment ID): 628023, 633688

Concern Statement: The SAMP needs a stronger “stop doing” function integrated into AM implementation.

Response: In general, AM programs for species at risk can make two types of errors: 1) not implementing actions that would benefit the species (a conservation risk); and 2) implementing actions that do not benefit the species (a waste of resources). The comment is concerned about the second type of error. The intent of the SAMP is to put in place strong science programs and experimental designs which reduce the likelihood of both types of errors, as described in Chapters 3 and 4 of the Draft SAMP, and in Appendices C, D, E, F and G. Due to the high amount of variability in some biological indicators, it will take several years before we know with confidence whether or not certain actions are effective (e.g., 7 years to determine if IRCs are increasing the catch per unit effort of age-0 pallid sturgeon, as described in Appendix E.1). Prematurely stopping an action (e.g., discontinuing IRCs after fewer than 7 years) could cause the first type of error.

Representative Quotes (Correspondence ID): 172
Comments (Comment ID): 641807

Concern Statement: Additional information is requested about Big Question 5: Passage, drift and recruitment, Level 2 initial action involving Fort Peck flows and drawdowns. What types of flow modifications and drawdown are under consideration; what constraints have been put into place. The SAMP should clarify these issues (Section 4.4.2).

Response: Changes to Fort Peck flows and drawdown of Lake Sakakawea are not part of the preferred alternative of the MRRMP-EIS. Uncertainty still surrounds what flow adjustments may be needed at Fort Peck to provide favorable conditions to encourage pallid sturgeon recruitment in the Upper Basin. USACE has committed, in an amendment to the Biological Assessment, to work with USFWS and MRRIC to review previous information and information generated since the Effects Analysis to formulate test flows from Fort Peck and an AM framework for their implementation. Until this is completed it is not possible to describe the details of these actions.

Representative Quotes (Correspondence ID): 239
Comments (Comment ID): 642838

Concern Statement: Clarification is requested regarding was is meant by the statement “the SAMP lays out how different types of decisions could be made that are outside the scope of real-time water management.” Does the statement mean the SAMP does not apply to water management or will it be used to decide on flow releases outside the bounds of the Master Manual?

Response: The processes required for different types of AM decisions are described in Figure 13 of the SAMP. Actions outside of the current Master Manual would require going through the process to amend the Master Manual.

Representative Quotes (Correspondence ID): 239
Comments (Comment ID): 642902

Concern Statement: The AM portion of the preferred alternative is lacking in clarity and boundaries; any action outside the constraints of the current Master Manual should be coordinated with the state of North Dakota. This includes any flow actions that are part of the preferred alternative or any flow actions outside the bounds of the MRRMP-EIS as a result of future AM decision-making.

Response: The processes required for different types of AM decisions are described in Figure 13 of the SAMP. Actions outside of the current Master Manual would require going through the process to amend the Master Manual.

Representative Quotes (Correspondence ID): 239
Comments (Comment ID): 643015

Concern Statement: Support is stated for the ongoing propagation and augmentation of pallid sturgeon as long as the stocked fish are “pure” pallid sturgeon and the number of fish stocked are based on the best available science. The propagation program should be considered temporary until natural levels of recruitment are obtained.

Response: The statement is consistent with USFWS decision criteria for halting Propagation and Augmentation, which are described in Section 4.1.1 of the SAMP, and is also consistent with the goals for population augmentation, described in Section 4.2 of the SAMP. The Pallid Sturgeon Basin-wide Stocking and Augmentation Plan is being developed by the Pallid Sturgeon Recovery Team.

Representative Quotes (Correspondence ID): 237
Comments (Comment ID): 643064

Concern Statement: The numerous administrative and regulatory process requirements may slow movement of management actions during implementation of the SAMP; therefore “action forcing” criteria should be developed to ensure appropriate changes are made in a timely manner within both the scientific and administrative portions of the SAMP. Additionally, the full suite of actions that can be taken for listed species recovery should be evaluated in the Final EIS to reduce potential delays during implementation of the MRRP.

Response: The Final SAMP attempts to minimize process delays, while respecting established procedures (e.g., required steps for amending the Master Manual).

Representative Quotes (Correspondence ID): 183
Comments (Comment ID): 643925

Concern Statement: Monitoring program for the pallid sturgeon should include monitoring assistance with data gathering for Level 1 and Level 2 activities and revised to address the broader need implications of future Level 3 and Level 4 actions.

Response: The form of management actions and the form of monitoring will be reviewed and adjusted as required, when actions move from Level 2 to Levels 3 or 4. In general, population level monitoring will be the most important form of monitoring at Levels 3 and 4, as only actions shown to be effective at Level 2 (confirmed via action effectiveness monitoring) would be implemented at Levels 3 and 4.

Representative Quotes (Correspondence ID): 183
Comments (Comment ID): 643943

Concern Statement: Monitoring forage fish that are important to pallid sturgeon and also use of telemetry technology to evaluate habitat use should be implemented.

Response: Both forage fish and telemetry technology are being considered in the evaluation of the PSPAP by the Effects Analysis Team. This evaluation is examining the costs and benefits of various components of monitoring. Ongoing progress of the PSPAP review (and opportunities for comment) can be accessed here: <https://mcolvin.github.io/PSPAP->

Reboot/. The PSPAP review began with a review of all potential objectives for the PSPAP at a workshop held on March 21, 2017 at the Missouri River Natural Resources Conference, which was attended by USFWS.

Representative Quotes (Correspondence ID): 183
Comments (Comment ID): 643944

Concern Statement: The ongoing and/or future Pallid Sturgeon Population Assessment Program should be continued and described in more detail in the Final EIS.

Response: The PSPAP is described in Chapter 4 and Appendix D of the SAMP.

Representative Quotes (Correspondence ID): 183
Comments (Comment ID): 643955

Concern Statement: The approach to AM implementation should be simplified to four steps identified by USFWS in the 2003 BiOp: (1) identify desired outcomes, (2) implement management actions to achieve desired results, (3) monitor, and (4) make adjustments based on new information.

Response: The approach taken to AM in the SAMP reflects the need to use Level 1 and Level 2 research to reduce critical uncertainties that affect decisions about which management actions to implement at Levels 3 and 4. In general, AM programs for species at risk can make two types of errors: 1) not implementing actions that would benefit the species (a conservation risk); and 2) implementing actions that do not benefit the species (a waste of resources). This commenter is concerned about the first type of error. Other commenters are concerned about the second type of error. The intent of the SAMP is to put in place strong science programs and experimental designs which reduce the likelihood of both types of errors, as described in Chapters 3 and 4 of the Draft SAMP, and in appendices C, D, E, F and G. USACE is not “performing research as a surrogate for evaluating the effects of management actions.” Instead, the Draft SAMP describes how research, Level 2 and Level 3 actions, and action effectiveness monitoring can collectively provide the most effective set of strategies for the listed species.

Representative Quotes (Correspondence ID): 191
Comments (Comment ID): 644028

Concern Statement: The Big Questions for the Lower Missouri River appear to be focused on age-0 pallid sturgeon and should be expanded to include all life stages and the full range of management actions to address the life cycle needs of the pallid sturgeon.

Response: As illustrated in Figure 61 of the SAMP, USACE is indeed considering all life stages of the Pallid Sturgeon, not only age-0, though age-0 appears to be the greatest bottleneck in the population. Various actions (Intake, creation of spawning habitat, population augmentation) address life stages other than age-0. The recent analysis of fish condition under the New Information process (described in Section 4.1.2.4 of the Draft SAMP), may lead to more research into other life stages, and potentially future management actions.

Representative Quotes (Correspondence ID): 224
Comments (Comment ID): 644408

Concern Statement: Flow release using AM may affect spring planting of crops and fall harvesting. Request that any alternative which includes AM allow the maximum amount of time between approval and implementation of flow releases and associated water

risers to give impacted residents and businesses the opportunity to prepare and make appropriate protective decisions.

Response: Effects on agricultural land (and other human considerations) would be considered prior to the implementation of spring or fall flow pulses. The processes required for different types of AM decisions are described in Figure 13 of the SAMP. Actions outside of the current Master Manual would require going through the process to amend the Master Manual.

Representative Quotes (Correspondence ID): 224
Comments (Comment ID): 644411

Concern Statement: Doubt is expressed that answers to Big Questions 1-4 can be answered by passively monitoring existing USACE operated flows (SAMP, Section 4.2.4, Table 43). Only Alternative 2 aims at approximating natural flows.

Response: If monitoring over nine years and historical data provide insufficient contrast in flows to assess the benefits of spawning cue flows, then a Level 2 test spawning flow would be implemented. The monitoring designs are not purely “passive” and will seek to make use of both reproductively ready hatchery fish and intensive telemetry to maximize the rate of learning (to be described in Appendix E.4 in the Final SAMP). The intent of the monitoring effort is to distinguish between two competing hypotheses:

- A. Pallid sturgeon spawn with or without managed spring flow pulses, and therefore such pulses are not required for spawning (conclusion of Independent Science Advisory Panel [ISAP, Doyle et al. 2011*]), or
- B. Naturalization of the flow releases from Gavins Point Dam will improve flow cues in the spring for aggregation and spawning, increasing reproductive success (a hypothesis evaluated in the recent Effects Analysis).

* Citation: Doyle M, Murphy D, Bartell S, Farmer A, Guy C, Palmer M. 2011. Missouri River Recovery Program, Independent Science Advisory Panel Report on Spring Pulses and Adaptive Management. U.S. Institute for Environmental Conflict Resolution and Oak Ridge Associated Universities, Third Party Science Neutral.

Representative Quotes (Correspondence ID): 166
Comments (Comment ID): 644851

Concern Statement: Hope that the AM as adopted in the ROD will be sufficient to ascertain ecosystem signals of distress for the three species of concern and prevent further endangered species listing.

Response: While the SAMP focuses on the listed species, ecosystem effects are being considered.

Representative Quotes (Correspondence ID): 166
Comments (Comment ID): 644886

Concern Statement: The MRRMP-EIS ROD should integrate the content of the SAMP and acknowledge that it is a living document that draws from the other alternatives analyzed as part of the NEPA process and not be hindered by a limited ROD.

Response: The processes required for different types of AM decisions are described in Figure 13 of the Draft SAMP. Just like the Final EIS and Final SAMP, the ROD will describe the approach to implementation which relies heavily on the SAMP.

Representative Quotes (Correspondence ID): 229
Comments (Comment ID): 644898

Concern Statement: A section should be added to both the EIS and SAMP on possible impacts to the piping plover science and proposed management actions pending results of the metapopulation study.

Response: Section 3.4 of the EIS and Chapter 3 of the SAMP describe the metapopulation study, but do not attempt to foresee the outcome of the study or its impact on piping plover science or proposed management actions. Once the study is complete the results will inform the ongoing AM process.

Representative Quotes (Correspondence ID): 229
Comments (Comment ID): 644900

Concern Statement: The overall philosophy of the Pallid Sturgeon Populations Augmentation Program should shift to place more emphasis on the quality of stocked fish rather than the quantity as is emphasized in the Draft EIS. Quality of stocked fish should be recognized as a limiting factor and addressed in the SAMP. This can be achieved under big Question 6, Population Augmentation components 1 and 2.

Response: Quality of fish is a major concern under discussion by the Pallid Sturgeon Recovery Team which is working to update the Pallid Sturgeon Basin-wide Stocking and Augmentation Plan.

Representative Quotes (Correspondence ID): 245
Comments (Comment ID): 644916

Concern Statement: The stated goal of increasing pallid sturgeon recruitment to age-1 is too simplistic to understand all the involved mechanisms and thus insufficient for the SAMP; USACE should develop sub-metrics such as prey species abundance, competitor abundance, substrate type, and other factors of importance in the conceptual models.

Response: All of the factors listed are under consideration in the re-evaluation of the PSPAP. This evaluation is examining the costs and benefits of various components of monitoring. Ongoing progress of the PSPAP review (and opportunities for comment) can be accessed here: <https://mcolvin.github.io/PSPAP-Reboot/>.

Representative Quotes (Correspondence ID): 238
Comments (Comment ID): 645322

Concern Statement: Based on statements made by the ISAP supporting additional flow releases, an SAMP should be prepared for the Lower River (below Gavins Point) outlining restoration practices to prevent further species decline including higher than prescribed flow releases, lower base flows and sediment management.

Response: All of the actions listed by the commenter were evaluated in the Effects Analysis. The Independent Science Advisory Panel (Doyle et al. 2011; pg. 1-2) concluded that:

“Pallid sturgeon have spawned in the lower Missouri River in all years for which data are available, with and without managed spring pulses. Based on that information, the ISAP concludes that the spring pulse management action, as currently designed, is unnecessary to serve as a cue for spawning in pallid sturgeon.”

Representative Quotes (Correspondence ID): 238

Comments (Comment ID): 645329

Concern Statement: Clarification is requested for a statement contained in the EIS under Alternative 2 – Actions would ultimately be implemented through AM as impediments to implementation were removed. How would the SAMP respond to changing implementation conditions?

Response: The phrasing is intended to indicate that some of the actions in Alternative 2 would not be fully implemented without first removing barriers to implementation such as an unacceptable level of HC impacts.

Representative Quotes (Correspondence ID): 242
Comments (Comment ID): 645499

Concern Statement: USACE should follow the SAMP process by constructing one IRC site and monitoring its performance and impacts on the listed species and human considerations before constructing all 12 sites.

Response: The statistical power analysis in Appendix E.1 shows that you need at least 7 years of monitoring multiple treatment and control paired sites to have adequate confidence in a conclusion regarding the effects of IRCs on catch per unit effort of age-0 pallid sturgeon. Ultimately, the Technical Team syntheses of evidence (reviewed by ISAP) will determine whether or not it is appropriate to continue, adjust, or stop an action and whether to maintain, adjust, or reject a hypothesis.

Representative Quotes (Correspondence ID): 228
Comments (Comment ID): 645639

Concern Statement: Socioeconomic analyses should inform the adaptive management process and be integrated into decision making regarding future management actions and/or adjustments of management actions of the preferred alternative as they are implemented.

Response: Socioeconomic analyses are described in Section 5 of the SAMP.

Representative Quotes (Correspondence ID): 228
Comments (Comment ID): 645810, 645812, 646297, 645813

Concern Statement: State governments should be accepted as active participants in any future decisions that affect pallid sturgeon or other fish and wildlife resources within the SAMP.

Response: The avenues for state involvement are detailed in the Governance section of the SAMP.

Representative Quotes (Correspondence ID): 236
Comments (Comment ID): 645816, 646299, 646301, 646300

Concern Statement: The Final EIS should be more explicit about the length of time monitoring will need to be conducted in order to make adjustments to ensure the project is successful for pallid sturgeon recruitment.

Response: Appendix E.1 clearly describes the duration of monitoring of Level 2 IRC actions (7 years, based on the staircase design), and the gradual expansion of IRCs to Levels 3 and 4 (if shown to be effective) is described in Table 42 of the Draft SAMP. Monitoring of the effects of flows on pallid sturgeon movement, aggregation and reproduction will occur for nine years after the ROD, as described in Table 42 and Section 4.2.6.6 of the

Draft SAMP. Other extensions to Appendix E will provide similar information for other Level 2 actions.

Representative Quotes (Correspondence ID): 242
Comments (Comment ID): 645824

Concern Statement: A mechanism should be created for the future inclusion of newly listed endangered species into the adaptive management program.

Response: If a new species is listed USACE would re-consult with USFWS.

Representative Quotes (Correspondence ID): 166
Comments (Comment ID): 644890

Concern Statement: The interagency coordination language contained in the last paragraph of Section 6.10.1 should be incorporated into Chapter 4 describing how AM will be implemented for the preferred alternative.

Response: The Final SAMP has been modified as suggested.

Representative Quotes (Correspondence ID): 183
Comments (Comment ID): 643958

Concern Statement: Existing constraints on the volume of flow which can be used to create ESH or potentially benefit the pallid sturgeon need to be addressed as part of the implementation of the preferred alternative.

Response: The preferred alternative includes nine years of study of existing spring pulses from intervening tributary flows to better understand pallid sturgeon responses. Combined with existing data, it is possible this will be sufficient to determine if a spring pulse is necessary and the one-time test may not be needed. As stated in Section 2.10 of the EIS, USACE will continue to analyze how this release, or others, may impact private landowners and to strategize how to minimize impacts over the next nine years.

Representative Quotes (Correspondence ID): 206
Comments (Comment ID): 645137

Concern Statement: The AM process described in the Draft EIS is too complex and convoluted to enable work to be completed on schedule.

Response: The Plan provides detailed information on the strategy for addressing uncertainties for each species, a governance structure for the program as a whole, clearly defines roles and responsibilities for all participants and describes how data are managed and how program actions and results will be communicated and reported.

Representative Quotes (Correspondence ID): 191
Comments (Comment ID): 644031

TC4500 *Tribal Consultation and Coordination*

Concern Statement: USACE should place more emphasis on Tribal consultation with the 29 Tribes. Additionally, Tribal cultural property surveys and archeological surveys need to be conducted.

Response: USACE offered government to government consultation to each Tribe in the basin and had extensive interaction with members of the Standing Rock Tribe in development

of the EIS through MRRIC and several additional meetings. Appendix H of the EIS details the Tribal engagement that occurred throughout the process.

Representative Quotes (Correspondence ID): 10, 232

Comments (Comment ID): 627492, 627494, 627501, 645482

Concern Statement: Who are the 29 stakeholders (e.g., perhaps Indian Tribes)?

Response: At this time the following are the 29 stakeholders that hold a seat on the Missouri River Recovery Implantation Committee (MRRIC):

- Agriculture
- Conservation Districts
- Environmental/Conservations Organizations
- Fish and Wildlife
- Flood Control
- Hydropower
- Irrigation
- Local Government
- Major Tributaries
- Navigation
- Recreation
- Thermal Power
- Water Quality
- Water Supply
- Waterway Industries
- At Large

The 29 Tribes that have a seat at MRRIC are:

- Apsaalooke (Crow Nation)
- Assiniboine and Sioux Tribes of Fort Peck
- Blackfeet Tribe
- Cheyenne River Sioux Tribe
- Chippewa Cree Tribe of Rocky Boy's
- Crow Creek Sioux Tribe
- Eastern Shoshone Tribe
- Flandreau Santee Sioux Tribe
- Gros Ventre and Assiniboine Tribes of Fort Belknap
- Iowa Tribe of Kansas and Nebraska
- Kickapoo Tribe in Kansas
- Lower Brule Sioux Tribe
- Northern Arapaho Tribe
- Northern Cheyenne Tribe
- Oglala Sioux Tribe
- Omaha Tribe of Nebraska
- Osage Nation
- Ponca Tribe of Nebraska
- Prairie Band Potawatomi Nation
- Rosebud Sioux Tribe
- Sac and Fox Nation of Missouri in Kansas and Nebraska

- Santee Sioux Tribe of Nebraska
- Sisseton-Wahpeton Oyate
- Spirit Lake Sioux Tribe
- Standing Rock Sioux Tribe
- Mandan Hidatsa Arkikara Three Affiliated Tribes
- Turtle Mountain Band of Chippewa Indians
- Winnebago Tribe of Nebraska
- Yankton Sioux Tribe

Representative Quotes (Correspondence ID): 10
Comments (Comment ID): 627500

Concern Statement: The Oglala Sioux Tribe has its own ordinance for Tribal consultations; there are two types of consultation, government to government and Section 106.

Response: Thank you. We have received the Tribal ordinance and will follow it as well as all other regulations, treaties, and Executive Orders.

Representative Quotes (Correspondence ID): 57
Comments (Comment ID): 632123

Concern Statement: Tribal participation on MRRIC does not constitute full Tribal consultation and has been misrepresented in the Draft EIS.

Response: The EIS does not state that MRRIC participation constitutes full Government to Government Consultation. The Missouri River Recovery Implementation Committee (MRRIC) is a 70-member committee made up of federal, state, Tribal, and stakeholder representatives from throughout the basin. MRRIC is authorized by Section 5018 of the Water Resources Development Act of 2007 and established by the Assistant Secretary of the Army for Civil Works. The Committee makes recommendations and provides guidance on a study of the Missouri River and its tributaries, as well as on the existing Missouri River recovery and mitigation plan. USACE understands this committee does not take the place of USACE and USFWS federal responsibility of Government-to-Government Consultation.

Representative Quotes (Correspondence ID): 232
Comments (Comment ID): 645354, 645431

Concern Statement: The Draft EIS contains rhetoric with respect to Tribal consultation; however, it makes no mention of Article XI, or of any other Treaty rights of our Tribes. The consultation process was not initiated in a timely manner to allow Tribes to have input in the alternative selection process.

Response: USACE, as an entity of the federal government has responsibilities to Tribes resulting from the federal trust doctrine, including treaties, executive orders, and agreements between the United States Government and Tribal Governments. USACE has extended the invitation in several letters over the course of the study, as detailed in Chapter 5 of the EIS and Appendix H.

Representative Quotes (Correspondence ID): 232
Comments (Comment ID): 645428

Concern Statement: Appendix H of the Draft EIS includes a list of meetings identified as "Alternatives Development Meetings," with the names of Tribes and dates of meetings.

However, the listing of the meetings contains no record of the participants or the discussion. Oglala Sioux Tribe meeting minutes reveal there was no discussion of the alternatives published in the Draft EIS. The entire listing in the appendix must be questioned.

Response: We acknowledge that there may have been a misunderstanding regarding the intent of the meeting. The power point presented at the meeting was titled as "Management Plan – Human Considerations Preliminary Results – DEIS Alternatives" However, the agenda did not call out that this was the main intent of the meeting.

Representative Quotes (Correspondence ID): 232
Comments (Comment ID): 645429

Concern Statement: There was no government-to-government consultation with any Tribes on the Draft EIS.

Response: USACE, as an entity of the Federal Government has responsibilities to Tribes resulting from the Federal Trust Doctrine, including treaties, Executive orders and agreements between the United States Government and Tribal Governments. USACE has extended the invitation in several letters over the course of the study, a detailed in Chapter 5 of the EIS and in Appendix H. Letters requesting government-to-government consultation on the Draft EIS were sent to Tribes on December 16th 2016. Letters requesting government-to-government consultation on the Biological Opinion and Final EIS development were sent to Tribes in December 2017. As Tribes are sovereign nations, they are able to request formal government-to-government at any time during this process.

Representative Quotes (Correspondence ID): 232
Comments (Comment ID): 645430

Concern Statement: The lack of government-to-government consultation in the preparation of the Draft MRRMP-EIS is evidenced by the fact that none of the Tribes' concerns are addressed in the plan. For example, Appendix E of the Draft EIS identifies "Special-Status Species" of the basin states. However, Tribes have identified riparian plant species of extreme concern, due to historical medicinal and nutritional uses of these species. However, these species are not identified in the Draft EIS.

Response: USACE offered government to government consultation to each Tribe in the basin and had extensive interaction with members of the Standing Rock Tribe in development of the EIS through MRRIC and several additional meetings. Appendix H of the EIS details the Tribal engagement that occurred throughout the process. Impacts to plant species important to the Tribes are addressed in the Tribal Resources section in Chapter 3 of the EIS.

Representative Quotes (Correspondence ID): 232
Comments (Comment ID): 645432

Concern Statement: USACE failed to comply with Article XI of the 1868 Fort Laramie Treaty, Executive Order 13175, the DoD American Indian and Alaska Native Policy, NEPA, and the Council on Environmental Quality regulations, all of which require timely and meaningful government-to-government consultation in the preparation of the Draft MRRMP-EIS.

Response: In August 2013, USACE held a series of six Tribal scoping meetings for the MRRMP-EIS at various locations across five states. Beyond fulfilling USACE

responsibilities under the National Environmental Policy Act (NEPA), the purpose of the Tribal scoping was to inform the Tribes about the proposed action and possible alternatives and provide meaningful opportunity for comment and participation in the process. Tribal scoping also allowed the Tribes to help identify the scope of issues to be addressed and to identify potentially significant issues related to the MRRMP-EIS. Letters of invitation were distributed to all 29 Tribes in the Missouri River Basin in mid-July 2013. The letters included a description of the project and a complete schedule of the Tribal scoping meetings. Meetings were held in Fort Peck and Billings, Montana; Bismarck, North Dakota; Vermillion, South Dakota; Pawhuska, Oklahoma; and Lawrence, Kansas. Members of the Tribes were invited to submit comments in person at the Tribal scoping meetings, by mail, email, or online. The letters also offered government-to-government consultation if the Tribal leaders requested at any time during the process.

Representative Quotes (Correspondence ID): 232
Comments (Comment ID): 645433

Concern Statement: The Draft EIS violates Section 106 of NHPA because (1) the surveys of cultural sites utilized for the impacts analysis are outdated and incomplete; (2) USACE failed to consult with the Tribal Historic Preservation Officers on traditional cultural properties, and USACE NHPA Section 106 procedures in Appendix C violate the Advisory Council requirements at 36 CFR Part 800; and (3) the assumptions in the computer model are flawed.

Response: USACE believes the analysis of impacts to Tribal Resources are properly considered given this is a programmatic EIS. A more-detailed examination of impacts would occur on a site-specific basis as projects are implemented. The model is intended as a planning tool to inform decision making rather than an exact representation of on the ground conditions. The inventory of cultural sites is sufficient to model the difference between the impacts of the different alternatives. Additionally, the preferred alternative does not include a reoccurring change to flow management.

Representative Quotes (Correspondence ID): 232
Comments (Comment ID): 645434, 645439, 645440, 645444

Concern Statement: USACE has not complied with Council on Environmental Quality Guidance on consultation with minority and Tribal communities. The Draft EIS contains erroneous information on the impacts of the Pick-Sloan program and MRRMP on Tribes, in part because USACE never conducted the required scoping as prescribed in the Council on Environmental Quality Guidance.

Response: The EIS baseline is with the dams in place and a hydrologic modeling of social effects of the construction of the dams on Tribes is beyond the scope of this EIS. The cumulative impacts analysis recognizes the effects of dams on the Tribes. Impacts to Tribal resources are acknowledged in the Tribal Resources section, the Cultural Resources section, and in various other sections of the environmental consequences chapter. USACE offered government to government consultation to each Tribe in the basin and had extensive interaction with members of the Standing Rock Tribe in development of the EIS through MRRIC and several additional meetings. Appendix H of the EIS details the Tribal engagement that occurred throughout the process. Early and continued scoping was conducted regularly as part of this process.

Representative Quotes (Correspondence ID): 232

Comments (Comment ID): 645477

Concern Statement: USACE never conducted the proper scoping, and the Draft EIS fails to identify or address Tribal concerns as a result.

Response: In August 2013, USACE held a series of six Tribal scoping meetings for the MRRMP-EIS at various locations across five states. Beyond fulfilling USACE responsibilities under the National Environmental Policy Act (NEPA), the purpose of the Tribal scoping was to inform the Tribes about the proposed action and possible alternatives and provide meaningful opportunity for comment and participation in the process. Tribal scoping also allowed the Tribes to help identify the scope of issues to be addressed and to identify potentially significant issues related to the MRRMP-EIS. Letters of invitation were distributed to all 29 Tribes in the Missouri River Basin in mid-July 2013. The letters included a description of the project and a complete schedule of the Tribal scoping meetings. Meetings were held in Fort Peck and Billings, Montana; Bismarck, North Dakota; Vermillion, South Dakota; Pawhuska, Oklahoma; and Lawrence, Kansas. Members of the Tribes were invited to submit comments in person at the Tribal scoping meetings, by mail, email, or online. The letters also offered government-to-government consultation if the Tribal leaders requested at any time during the process.

TC3500 *Guiding Regulations, Policies, Laws - Tribal*

Concern Statement: Tribal water rights and Tribal lands must be treated with respect in the Draft EIS.

Response: USACE has tremendous respect for the Tribes, their lands, and rights. The alternatives do not define, regulate, or quantify water rights or any other rights that the Tribes are entitled to by law or treaty. A description of Tribal water rights is provided in Section 6.5.

Representative Quotes (Correspondence ID): 26
Comments (Comment ID): 626693

Concern Statement: Tribal reserve water rights needs and treaties need to be acknowledged and factored into the Draft EIS impact analysis.

Response: The alternatives do not define, regulate, or quantify water rights or any other rights that the Tribes are entitled to by law or treaty.

Representative Quotes (Correspondence ID): 57, 232
Comments (Comment ID): 632098, 632124

Concern Statement: The Draft EIS totally ignores the treaty rights of the Great Plains Water Alliance. The requirement to honor treaty rights applies to USACE with the MRRMP. Consequently, the Draft EIS must include a description of the Indian Treaty rights within the study area, and describe how USACE will comply with the dictates of Executive Order 13175 to honor treaty rights.

Response: The alternatives do not define, regulate, or quantify water rights or any other rights that the Tribes are entitled to by law or treaty.

Representative Quotes (Correspondence ID): 232
Comments (Comment ID): 645357, 645414, 645415, 645419

Concern Statement: Indian water rights are treaty rights. The Draft EIS appears designed to justify the continuation of USACE current water management under the Master Manual. USACE operations under the Master Manual infringe on Indian reserved water rights, by degrading Tribal water supplies in favor of downstream navigation flows.

Response: Modifying the operation of the system for other purposes other than endangered species is outside the scope of the analysis. The alternatives do not define, regulate, or quantify water rights or any other rights that the Tribes are entitled to by law or treaty.

Representative Quotes (Correspondence ID): 232
Comments (Comment ID): 645416

Concern Statement: The preferred alternative potentially diminishes the feasibility of Indian water projects by increasing the costs, as acknowledged by USACE on page 3-513 of the Draft EIS. Thus, the Draft EIS infringes on Indian reserved water rights.

Response: The alternatives do not define, regulate, or quantify water rights or any other rights that the Tribes are entitled to by law or treaty.

Representative Quotes (Correspondence ID): 232
Comments (Comment ID): 645421

Concern Statement: USACE Missouri River operations pursuant to the Master Manual degrade Indian waters and create uncertainty for the availability of water, thereby violating the trust responsibility and infringing on Indian reserved water rights.

Response: The alternatives do not define, regulate, or quantify water rights or any other rights that the Tribes are entitled to by law or treaty.

Representative Quotes (Correspondence ID): 232
Comments (Comment ID): 645422

Concern Statement: The Draft EIS proposes alternatives that involve the use and management of water subject to our Winter Doctrine claims. USACE should revise the Master Manual, in order to avoid jeopardy to the listed species and to mitigate the impacts of the Pick-Sloan program on the Tribes.

Response: The preferred alternative does not include re-occurring changes to flow management. The alternatives do not define, regulate, or quantify water rights or any other rights that the Tribes are entitled to by law or treaty.

Representative Quotes (Correspondence ID): 232
Comments (Comment ID): 645424

Concern Statement: The Draft EIS fails to acknowledge that the exercise of Tribal water rights in the future could affect USACE's ability to implement the preferred alternative. The Draft EIS should propose alternatives that involve revisions to the Master Manual in order to recreate a natural hydrograph for the lower Missouri River, and for the protection of future Indian water uses in the upper basin.

Response: The preferred alternative does not include re-occurring changes to flow management. The alternatives do not define, regulate, or quantify water rights or any

other rights that the Tribes are entitled to by law or treaty. A description of Tribal water rights is provided in Section 6.5.

Representative Quotes (Correspondence ID): 232
Comments (Comment ID): 645426

Concern Statement: USACE must review the Missouri River Master Manual, and make changes as needed to fulfill Tribal water rights in the upper basin.

Response: Updates to the Master Manual are outside the scope of this analysis other than the changes in operations that were examined for their potential to benefit endangered species. The alternatives do not define, regulate, or quantify water rights or any other rights that the Tribes are entitled to by law or treaty. A description of Tribal water rights is provided in Section 6.5.

Comments (Comment ID): 645483

CC1000 Consultation and Coordination: General Comments

Concern Statement: The annual consultation with the North Dakota Emergent - Interagency Emergent Habitat Sandbar Team should be continued.

Response: USACE plans to continue the interagency emergent sandbar habitat meetings on an annual basis. USACE will also conduct project-specific scoping and engagement as appropriate. North Dakota will also have the opportunity to participate in the fall science meetings as a MRRIC member.

Representative Quotes (Correspondence ID): 25
Comments (Comment ID): 626692

Concern Statement: The Final EIS should provide for direct consultation with affected states for consideration of flow modifications or deviations outside the bounds of the current Master Manual.

Response: The consultation process is outlined in the SAMP including a description of state involvement.

Representative Quotes (Correspondence ID): 3
Comments (Comment ID): 645649

Concern Statement: Decision-making within the SAMP needs to be open and transparent. All of the states represented in MRRIC agree that consultation and coordination with the states' governor's offices on matters of high-consequence is imperative.

Response: As described in Section 2.3 of the Draft SAMP, each state will have responsibilities within their boundaries that could be affected in this process and the AM governance structure does not and will not change or impeded on any of the rights and responsibilities of a state codified by law. Annual operating plans will continue to be provided each fall describing the planned operation of the reservoir system for the coming year under a variety of runoff conditions. The States will have the opportunity to provide comments on the draft annual operating plan at the fall public meetings or by providing written comments during the comment period. At any time, States may submit an official letter to USACE, commenting on any issue related to the Management Plan or

ongoing AM process. The States also have an additional role through their representation at MRRIC.

Representative Quotes (Correspondence ID): 46
Comments (Comment ID): 628581

Concern Statement: Should USACE choose an alternative other than Alternative 3, the process for creating flow changes needs to be clear to stakeholders and be aligned with the Master Manual.

Response: As stated in Section 2.4 of the SAMP, the decision process for the MRRP includes the mechanisms by which information about project and program performance, species status, system state, and other knowledge is gathered and evaluated, shared with agency managers, MRRIC, and stakeholders, and used to make improved implementation decisions. The decisions to implement flows would fall under what is described in the previous sentence.

Representative Quotes (Correspondence ID): 65, 69
Comments (Comment ID): 631574, 635065

Concern Statement: USACE should use the Bureau of Reclamation's "2007 Colorado River Interim Guidelines Record of Decision" as a benchmark for federal/state consultation.

Response: As described in Section 2.3 of the SAMP, each state will have responsibilities within their boundaries that could be affected in this process and the AM governance structure does not and will not change or impeded on any of the rights and responsibilities of a state codified by law. Annual operating plans will continue to be provided each fall describing the planned operation of the reservoir system for the coming year under a variety of runoff conditions. The States will have the opportunity to provide comments on the draft annual operating plan at the fall public meetings or by providing written comments during the comment period. At any time, States may submit an official letter to USACE, commenting on any issue related to the Management Plan or ongoing AM process. The States also have an additional role through their representation at MRRIC.

Representative Quotes (Correspondence ID): 158
Comments (Comment ID): 640080

Concern Statement: To be a true partnership, the Final EIS should provide for direct consultation with affected states regarding flow modifications or deviations outside the bounds of the current Master Manual and other aspects of MRRP implementation.

Response: The consultation process is outlined in the SAMP including a description of state involvement.

Representative Quotes (Correspondence ID): 96, 239
Comments (Comment ID): 640144, 645382

Concern Statement: MRRMP implementation will require a continued working relationship with stakeholders throughout the Missouri River basin and adoption of management practices that reflect the importance of flood control and navigation as well as the other uses authorized by Congress.

Response: Impacts to human considerations including flood risk management and navigation were assessed and reported under each alternative in the EIS. USACE plans to maintain working relationship with stakeholders throughout the Missouri River Basin.

Stakeholders will have the continued opportunity to engage with USACE and participate as a MRRIC member. USACE will continue to maintain the authorized purposes including flood control and navigation on the Missouri River.

Representative Quotes (Correspondence ID): 154
Comments (Comment ID): 640960

Concern Statement: States are lumped into the MRRMP-EIS as a “stakeholder” – this approach is inadequate and the basin states need to be identified in some unique form within the document.

Response: USACE plans to continue the interagency emergent sandbar habitat meetings on an annual basis. USACE will also conduct project-specific scoping and engagement as appropriate. North Dakota will also have the opportunity to participate in the fall science meetings as a MRRIC member. Furthermore, as described in Section 2.3 of the SAMP, each state will have responsibilities within their boundaries that could be affected in this process and the AM governance structure does not and will not change or impeded on any of the rights and responsibilities of a state codified by law. Annual operating plans will continue to be provided each fall describing the planned operation of the reservoir system for the coming year under a variety of runoff conditions. The States will have the opportunity to provide comments on the draft annual operating plan at the fall public meetings or by providing written comments during the comment period. At any time, States may submit an official letter to USACE, commenting on any issue related to the Management Plan or ongoing AM process. The States also have an additional role through their representation at MRRIC.

Representative Quotes (Correspondence ID): 185, 239
Comments (Comment ID): 641485, 643023

Concern Statement: Information regarding MRRIC’s involvement in the alternative development process as conveyed in the Draft EIS is incorrect and should be corrected.

Response: During the development of the Draft EIS, USACE sought and obtained feedback on the specification of management actions on a frequent basis. At various points in the iterative development of management options, predicted information on how the human considerations represented by MRRIC might be affected by the actions was provided.

USACE did not directly co-develop management actions with MRRIC, but the actions USACE created for evaluation were designed to incorporate specific human considerations it had heard from members. USACE was not able to analyze all member suggestions for management options (e.g., ‘off-channel bird habitat’) since some of these were not within the stated bounds of technical appropriateness or acceptability articulated by USFWS.

Representative Quotes (Correspondence ID): 107, 239
Comments (Comment ID): 643864, 645373

Concern Statement: Additional coordination with NPS may be required if management actions directly or indirectly affect NPS related resources.

Response: Each site-specific project would entail additional coordination with the appropriate Tribes, stakeholders, and agencies including NPS.

Representative Quotes (Correspondence ID): 183
Comments (Comment ID): 643957

Concern Statement: Southern Region standardized emergent sandbar habitat acres shown as available is contingent upon continued interagency coordination and consideration of the set-aside acres NPS has identified within its draft ESH Management Plan.

Response: Continued interagency coordination and consideration of areas for vegetation management will continue to occur, however the modeling is currently not able to take into account these types of considerations.

Representative Quotes (Correspondence ID): 183
Comments (Comment ID): 643959

Concern Statement: The Mississippi River Commission along with the landowners protected, and those not protected, by the MR&T project should be considered and involved in the decision process of any modifications within the Mississippi Watershed that impacts downstream flood control and navigation.

Response: USACE will conduct project-specific scoping and engagement as appropriate. Furthermore, actions implemented as part of this Management Plan will not significantly alter or change in flows to the Mississippi from the Missouri. Section 3.24, beginning on page 3-585 of the Draft EIS describes resources in the Middle Mississippi River that could be potentially affected by the alternatives and reports the evaluated impacts.

Representative Quotes (Correspondence ID): 196
Comments (Comment ID): 644163

Concern Statement: Only five economic models on human considerations were presented to the ISETR for review and evaluation; moving forward with any alternatives prior to the completion of these economic models is inappropriate.

Response: The Human Consideration models presented to the ISETR for review included those areas that did not have previously USACE-approved models. These included Water Supply, Thermal Power, Irrigation, Cultural Resources, and Navigation. These models underwent the USACE model approval process and have all been approved by USACE-Headquarters for use on the Management Plan. The models used for the other HC resource areas including hydropower, flood risk management, interior drainage, recreation had already been previously USACE approved for use and therefore, did not need to undergo review approval.

Representative Quotes (Correspondence ID): 176
Comments (Comment ID): 644758

Concern Statement: If spatial location output is available, then make it public and show us the maps- preferably, in a form that can be compared with other datasets. We hope for this kind of transparency to emerge from the MRRMP and SAMP.

Response: USACE is obligated to protect certain spatial information related to cultural resources and private property.

Representative Quotes (Correspondence ID): 166
Comments (Comment ID): 644884

Concern Statement: USACE should produce a new biological assessment before selecting a preferred alternative.

Response: USACE has prepared a Biological Assessment and has completed consultation with USFWS in accordance to Section 7 of ESA. USFWS issued a non-jeopardy Biological Opinion on the USACE proposed action.

Representative Quotes (Correspondence ID): 240
Comments (Comment ID): 645420

Concern Statement: In the Final EIS, the document should be modified to state that MRRIC did not reach a consensus agreement, and that there was little or no tradeoff discussion before the committee regarding the issues discussed within Volume 6 on page 140.

Response: The acronym PrOACT stands for (1) **P**roblem definition, (2) **O**bjectives, (3) **A**lternatives, (4) **C**onsequences, and (5) **T**radeoffs. MRRIC was engaged in each step of the process. The problem statement was shared with MRRIC and MRRIC's input was included in the final version of the problem statement and included in the EIS. Species objectives were shared with MRRIC and were evaluated by ISAP. ISAP comments and MRRIC feedback were considered and incorporated where appropriate into the final versions of the objectives. While it is true that individual MRRIC members or MRRIC as a whole did not design elements of the alternatives such as specific types of habitats, or flow management actions, the alternatives were developed by USACE using the results of the effects analysis which was reviewed extensively by ISAP and MRRIC. MRRIC was involved in evaluation of test alternatives and in two rounds of proxy analyses of consequences and tradeoffs. Individual MRRIC members and MRRIC as a committee have had opportunity to provide comment or recommendation regarding the process and its outcome from 2012 to the present. After release of the Draft EIS, MRRIC members requested, and were given opportunity, to come to consensus recommendations on their "common ground" issues related to the EIS. There also will be opportunity for MRRIC to participate in tradeoffs analysis of specific management actions through participation in the adaptive management process as described in Chapters 2 and 5 of the SAMP.

Representative Quotes (Correspondence ID): 242
Comments (Comment ID): 645588

Concern Statement: An assessment of the pros and cons associated with each the alternatives has not occurred at a MRRIC meeting and should.

Response: The acronym PrOACT stands for (1) **P**roblem definition, (2) **O**bjectives, (3) **A**lternatives, (4) **C**onsequences, and (5) **T**radeoffs. MRRIC was engaged in each step of the process. The problem statement was shared with MRRIC and MRRIC's input was included in the final version of the problem statement and included in the EIS. Species objectives were shared with MRRIC and were evaluated by ISAP. ISAP comments and MRRIC feedback were considered and incorporated where appropriate into the final versions of the objectives. While it is true that individual MRRIC members or MRRIC as a whole did not design elements of the alternatives such as specific types of habitats, or flow management actions, the alternatives were developed by USACE using the results of the effects analysis which was reviewed extensively by ISAP and MRRIC. MRRIC was involved in evaluation of test alternatives and in two rounds of proxy analyses of consequences and tradeoffs. Individual MRRIC members and MRRIC as a committee have had opportunity to provide comment or recommendation regarding the process and its outcome from 2012 to the present. After release of the Draft EIS, MRRIC members requested, and were given opportunity, to come to consensus recommendations on their "common ground" issues related to the EIS. There also will be opportunity for MRRIC to

participate in tradeoffs analysis of specific management actions through participation in the adaptive management process as described in Chapters 2 and 5 of the SAMP.

Representative Quotes (Correspondence ID): 242
Comments (Comment ID): 645589

Concern Statement: The Final EIS needs to address what issues might prevent USACE from having time to engage MRRIC in discussion of trade-offs and their preference for one approach over another regarding implementation of specific management actions.

Response: The Final SAMP clarifies the type of time-sensitive situations where engaging with the MRRIC process may not be possible (e.g., emergency situations, acting within available budget time-windows, etc.).

Representative Quotes (Correspondence ID): 242
Comments (Comment ID): 645590

Concern Statement: Greater clarity should be provided in the Final EIS on USACE plans to engage the state fish and wildlife agencies about federal actions that would affect management of endemic wildlife within their borders.

Response: State wildlife and resource agencies would be engaged on site specific projects as part of scoping and coordination. As is required under NEPA, federal actions would not be implemented without undergoing and completing the NEPA process where state agencies and the public would have the opportunity to engage. Furthermore, at any time, States may submit an official letter to USACE, commenting on any issue related to the Management Plan or ongoing AM process.

Representative Quotes (Correspondence ID): 177
Comments (Comment ID): 645807

Concern Statement: States retain the right to comment or request consultation outside of MRRIC, FWCA, and ADP processes on any issue related to the MRRMP or ongoing SAMP implementation via official letter.

Response: Noted. At any time, States may submit an official letter to USACE, commenting on any issue related to the Management Plan or ongoing AM process.

Representative Quotes (Correspondence ID): 236
Comments (Comment ID): 645808

RF1000 *References: General Comments*

Concern Statement: Incorporating the ongoing nature of scientific research and results would enhance credibility of the Draft EIS, particularly since 2003.

Response: One of the initial undertakings in the development of the MRRMP-EIS was the collection of all updated and current scientific information available on the three species as part of an Effects Analysis. As part of this effort, all available scientific literature, databases and models regarding the three species were compiled, reviewed, and synthesized. The information emerging from the effects analysis is what was used to evaluate alternatives in the Draft EIS. This information and data will be continuously updated as part of the adaptive management process.

Representative Quotes (Correspondence ID): 162

Comments (Comment ID): 641193

Concern Statement: Within this Draft EIS, or rather the Management Plan outcomes, citizens of the Missouri River basin need for the operations to be based on tools with higher, and faster, predictive power since many reservoir decisions are made at watershed levels on monthly, weekly and daily bases.

Response: Real-time regulation of the Missouri River Mainstem Reservoir System is conducted by the Missouri River Basin Water Management office and is based upon the objectives in the Master Manual (USACE 2006). Alternative formulation and the interaction with the Master Manual is described throughout the Draft EIS in multiple sections, primarily within Chapter 2 and 3. For the purposes of this study, a ResSim model was created that allows simulation of an 82-year period-of-record. This ResSim model uses historic data for alternative comparison. This study is separate from the daily regulation decisions made by the Water Management office. Actual real-time regulation of the reservoir system is accomplished using the best information and tools available and is adjusted to respond to changing conditions on the ground.

Representative Quotes (Correspondence ID): 166
Comments (Comment ID): 644879

Concern Statement: The Draft EIS does not use the most recent data on the biological opinion available from the 2010 Independent Science Advisory Panel recommendations.

Response: One of the initial undertakings in the development of the MRRMP-EIS was the collection of all updated and current scientific information available for each of the species of concern. As part of this effort, all available scientific literature, databases and models regarding the three species were compiled, reviewed, and synthesized. The information emerging from the Effects Analysis is what was used to evaluate alternatives in the Draft EIS. This information and data will be continuously updated as part of the adaptive management process.

AMP1000 *Governance of the Adaptive Management Program*

Concern Statement: Text is proposed for inclusion in Section 2.3.8.1 of the SAMP providing a more defined role for state governments and agencies in the implementation of the MRRP.

Response: The consultation process is outlined in the SAMP including a description of state involvement.

Representative Quotes (Correspondence ID): 3
Comments (Comment ID): 645654

Concern Statement: For high-consequence decisions there needs to be an avenue for direct consultation with state agencies; this consultation process needs to be separate and independent from MRRIC, FWCA, and annual operating plan processes already in existence.

Response: The consultation process is outlined in the SAMP including a description of state involvement.

Representative Quotes (Correspondence ID): 3, 25, 206, 222, 228, 236
Comments (Comment ID): 645655, 626689, 644831, 645151, 645154, 646301, 645816, 646299, 645809, 645802, 645803

Concern Statement: The AM process compromises the authority of the governors in the river basin to a lower priority in decision-making; a suggestion is made that they be given a higher priority within the AM process.

Response: The consultation process is outlined in the SAMP including a description of state involvement.

Representative Quotes (Correspondence ID): 34, 222
Comments (Comment ID): 628335, 644783

Concern Statement: The SAMP fails to outline options for notifying states when management actions may occur outside the bounds of the Master Manual. The SAMP should be modified to add additional consultation with states at specific trigger points or at least for high consequence events.

Response: The consultation process is outlined in the SAMP including a description of state involvement.

Representative Quotes (Correspondence ID): 158
Comments (Comment ID): 640079

Concern Statement: Replacement text is proposed for inclusion in Section 2.3.8.1 describing the states' role in the implementation of the MRRP. The proposed replacement text essentially indicates that the AM process does not change or impede any of the rights and responsibilities of a state codified by law.

Response: The consultation process is outlined in the SAMP including a description of state involvement.

Representative Quotes (Correspondence ID): 236
Comments (Comment ID): 643306

Concern Statement: MRRIC representatives should communicate with MRRIC State representatives as a mechanism for communicating with interested state agencies and relaying their concerns to MRRIC.

Response: Concur.

Representative Quotes (Correspondence ID): 236
Comments (Comment ID): 643312

Concern Statement: Various agencies encourage continued engagement with partners and stakeholders to ensure the success of conservation efforts within the Missouri River basin.

Response: The expertise, research and management actions by Montana Fish, Wildlife and Parks and other state fish and wildlife agencies are indeed absolutely critical to efforts to conserve and recover pallid sturgeon. The review of the Draft EIS is an opportunity for Montana, Fish, Wildlife and Parks to comment on fundamental objectives in the MRRMP-EIS.

In addition, the process currently underway to revise the Pallid Sturgeon Population Assessment Program (PSPAP) presents another opportunity to comment on the hierarchy of objectives guiding population monitoring. Ongoing progress (and opportunities for comment) can be accessed here: <https://mcolvin.github.io/PSPAP-Reboot/>. The PSPAP review began with a review of all potential objectives for the PSPAP at a workshop held on March 21, 2017 at the Missouri River Natural Resources Conference, including the fundamental objective stated in comment 646300. This workshop was attended by two representatives of Montana Fish, Wildlife and Parks.

Representative Quotes (Correspondence ID): 183, 236
Comments (Comment ID): 643946, 646300

Concern Statement: Figure 7 of the SAMP (page 18) should be modified to: (1) have the Agency Management Team Box overlap with the various Team levels, and (2) better identify interactions between the Management Team and the Bird, Fish and Human Considerations Team.

Response: There are many interactions among the groups represented on Figure 7. We deliberately decided to not add arrows or overlap boxes in this figure to keep it simple. The interactions among groups are described in the text, and in Figures 20 and 24 of the SAMP. The process of interactions has been substantially revised since the Draft EIS was written, through extensive consultation with the MRRIC AM Governance Planning Ad Hoc Group and modifications are documented in the Final SAMP.

Representative Quotes (Correspondence ID): 107
Comments (Comment ID): 644297, 644386, 644429

Concern Statement: Section 2.3.1 (page 73) last paragraph of the SAMP should be modified to indicate the USFWS Regional Director will approve recommendations emerging from the SAMP process rather than suggesting he initiates them.

Response: This is a reasonable suggestion and the text has been reworded.

Examples of such decisions include the *approval* ~~development~~ of or *recommended* changes to targets and decision criteria, disposition of hypotheses, introduction of new management actions, advancement of implementation levels for pallid sturgeon, etc.

Representative Quotes (Correspondence ID): 107
Comments (Comment ID): 644387

Concern Statement: The Human Considerations Work Group should be the full MRRIC membership. Additionally, MRRIC meetings should be at different times than fish and bird team meetings to allow MRRIC members to participate on a species team and also the Human Considerations Team.

Response: Considerable dialogue has occurred on these issues with the AM Governance Planning Ad Hoc Group since the Draft EIS was released. The Fish, Bird and HC Work Groups (with representatives nominated and approved by MRRIC) will provide draft recommendations for consideration by MRRIC, but the Work Groups cannot themselves make any recommendations to the Fish, Bird and HC Teams. These modifications are documented in the Final SAMP.

Representative Quotes (Correspondence ID): 107
Comments (Comment ID): 644389

Concern Statement: The line of communication to ISAP should be through the appropriate organization as prescribed in panel documents rather than from a Technical Support group directly to either ISAP or ISETR (SAMP, Section 2.3.4, page 83).

Response: We should clarify that the Technical Team is a group of independent scientists charged with synthesizing the complex scientific information to support decision making; we believe interaction between the Technical Team and ISAP will be beneficial to both. There are two different kinds of engagements with ISAP and ISETR. The first kind of engagement is a formal review of documents, such as the IEPR, or reviews of the Draft SAMP, which we agree should operate through the appropriate procedures for the Team, MRRIC and USACE. The second kind of engagement is an informal exchange (e.g., on the first day of MRRIC meetings, at the fall science meeting, at the AM workshop) between Technical Team members and ISAP/ISETR members, as well as any MRRIC members who are interested in attending. These informal and open exchanges offer valuable opportunities for early input into draft products and insights, and should be maintained. Such informal advice (consistent with the advisory role embodied in the 'A' of ISAP) does not undermine the independence of ISAP and ISETR, as they are not engaging in actually doing any of the technical work.

Representative Quotes (Correspondence ID): 107
Comments (Comment ID): 644415

Concern Statement: The role and make-up of the Technical Support Group needs to be better defined; a group membership list should be maintained. This list should be provided to MRRIC for review and comment.

Response: This is a reasonable suggestion and such a list will be provided once the composition of the Technical Team is finalized.

Representative Quotes (Correspondence ID): 107
Comments (Comment ID): 644417

Concern Statement: The roles and responsibilities depicted in the SAMP should be consolidated into fewer positions.

Response: We will consider ways to make the process and program as efficient as possible, while still retaining the appropriate participation and collaboration.

Representative Quotes (Correspondence ID): 107
Comments (Comment ID): 644417

Concern Statement: The SAM Work Group is not needed for SAMP implementation as the Bird, Fish, and Human Considerations Work Groups can bring appropriate information and recommendations to MRRIC.

Response: Agreed. At the May 2017 MRRIC meeting, it was proposed to sunset the SAM Work Group at the August 2017 MRRIC meeting. The SAM Work Group is not reflected in the Final SAMP.

Representative Quotes (Correspondence ID): 107
Comments (Comment ID): 644426

Concern Statement: The Fall Science Meeting and Annual AM Workshop should not be held at prescribed times but rather occur after data and analysis reports are made available and time allocated for review; flexibility is key.

Response: We disagree. Having firm dates allows for better preparation and planning by the Technical Team, ISAP/ISETR, MRRIC, and the Bird, Fish and HC Teams. Experience in other AM programs has demonstrated that fixed dates for such review meetings result in a more efficient processing of scientific information into insights for managers, and expedite the development of data management systems.

Representative Quotes (Correspondence ID): 107
Comments (Comment ID): 644428

Concern Statement: Work Groups for MRRIC should have co-points of contact to share workload management responsibilities.

Response: This is a reasonable suggestion which will be discussed with MRRIC and the AM Governance Planning Ad Hoc Group.

Representative Quotes (Correspondence ID): 107
Comments (Comment ID): 644431

Concern Statement: A recommendation is made to maintain an ISAP and a separate ISETR panel and that a rotational process be established for panel membership. The SAMP (Section 2.3.7.3, page 97) should be modified to address the two roles of each panel – review and advisory. As the SAMP is implemented, the primary role of each panel should be reviewed. Any advisory role should be done in a manner to maintain the neutrality of the panels.

Response: The arguments for combined and separate panels were summarized in a presentation by Dr. Craig Fischenich on January 31, 2017 at the MRRIC meeting. As noted by Dr. Fischenich in his presentation, the members of ISAP and ISETR panels favor a combined panel for the following reasons:

- There are often “cross-cutting” opportunities where collaboration between physical, biological and social scientists might be able to identify more effective ways to meet some biological goals.
- The often-repeated goal of MRRIC to “...recover the species while minimizing the impact to human considerations...” suggests integration of physical, biological and social perspectives might be able to provide some insights that separate natural and social sciences panels may not be able to provide.
- A single panel may afford the opportunity for science advisors and social science advisors to more readily discuss the diverse interactions, dependencies, opportunities, and constraints that challenge resource managers
- Evaluating the socio-economic and ecological trade-offs of proposed management actions would likely benefit from having a single panel
- Wherever possible, and particularly for issues that are likely to escalate to the attention of MRRIC, efforts should be made to secure panel consensus.
- A combined panel was used very effectively in the IEPR review of the Draft EIS. For all of the above reasons, it is preferable to retain a combined panel, with clear allocation of questions according to the expertise of panel members, as occurred in the IEPR.

Representative Quotes (Correspondence ID): 107
Comments (Comment ID): 644432, 644430

Concern Statement: The role of the Third-Party Science Neutral should involve coordination of the two panels and not technical review or expression of opinion.

Response: This comment is consistent with the description in the SAMP. In facilitating work by the Panel, the Third-Party Science Neutral needs to keep the panelists focused on the questions posed to the Panel, and to explore the degree of consensus where differing opinions emerge.

Representative Quotes (Correspondence ID): 107
Comments (Comment ID): 644433

Concern Statement: The organizational interactions utilized to develop the SAMP as described in Section 2.3.7.5 (page 100 lines 4-38) probably will not be necessary for implementation of the SAMP and should be eliminated.

Response: We disagree. Experience from other AM programs shows the need for a range of interactions with interested participants.

Representative Quotes (Correspondence ID): 107
Comments (Comment ID): 644434

Concern Statement: Membership of the Technical Teams as currently defined may include Federal and state agency personnel, university professors, and contractors selected to address the science aspects of the Program. The specific role of state fish and game agencies is unclear and needs to be clarified.

Response: If personnel from state fish and game agencies join the Technical Team, their roles would be the same as other members of the Technical Team, as described in the SAMP. In summary, these roles are to: 1) provide policy-neutral scientific analysis, modeling and assessments to the decision-making process, culminating in the annual AM report; and 2) providing policy-neutral AM expertise to the MRRP relevant to program and species objectives, updating the SAMP as needed.

Representative Quotes (Correspondence ID): 177
Comments (Comment ID): 644644

Concern Statement: Implementation of the SAMP and decision-making should not contradict existing regulatory paradigms and requirements without proper rulemaking.

Response: The Science and SAMP recognizes the need to respect existing regulations, procedures and requirements, as illustrated in Figures 13 and 21.

Representative Quotes (Correspondence ID): 222
Comments (Comment ID): 644784

Concern Statement: The SAMP governance structure is flawed and requires revision. For example, MRRIC membership is selected by USACE and there is the possibility of selecting members that are biased. Additionally, the MRRIC charter can be revised by removing key presumptions, such as requiring unanimous consensus.

Response: Comment noted. USACE does not share the view that ultimate selection of members by USACE or recommendations by consensus are flaws and the comment fails to explain the basis for these statements. MRRIC members are selected to represent their respective interest categories so some level of bias toward their interest category is understandable. The member selection process is transparent and MRRIC

members are allowed to comment on prospective new members and members up for renewal.

AMP1100 *Decision Needs to Adaptively Manage the MRRP*

Concern Statement: Since the preferred alternative does not contain any flow modifications (with the exception of a potential spring spawning cue release) the Final EIS and ROD should clearly state that adaptive management implementation would not include a flow modification outside the boundaries of the current Master Manual without consulting with affected states and preparing an additional EIS.

Response: The Final EIS fully describes the required procedures for revision of the Master Manual, beyond what is currently included in the Draft SAMP.

Representative Quotes (Correspondence ID): 3
Comments (Comment ID): 645653

Concern Statement: The SAMP needs a stronger “stop doing” function to more quickly eliminate hypotheses that lack quantitative scientific support.

Response: The history of science shows that there is indeed a risk of holding on to a hypothesis for too long in the face of evidence contradicting it*, but there is also a risk of prematurely rejecting a hypothesis. For example, the statistical power analysis in Appendix E.1 shows that you need at least 7 years of monitoring multiple treatment and control paired sites to have adequate confidence in a conclusion regarding the effects of IRCs on catch per unit effort of age-0 pallid sturgeon. Ultimately, the Technical Team syntheses of evidence (reviewed by ISAP) will determine whether or not it is appropriate to continue, adjust, or stop an action and whether to maintain, adjust, or reject a hypothesis.

Representative Quotes (Correspondence ID): 172
Comments (Comment ID): 642101

Concern Statement: A commitment should be contained in the Final EIS and SAMP to implement Level 3 and Level 4 actions within the 15-year period of the MRRMP.

Response: The tradeoffs between different learning strategies are described in Section 4.2.2 of the SAMP. The AM strategy needs to find the appropriate balance between three risks: 1) premature implementation of ineffective actions, which wastes resources; 2) excessive delay in implementing actions which would have helped the population; and 3) implementation of multiple concurrent actions without an ability to determine which actions are most effective, which makes future management adjustments more difficult. Level 4 actions are already being implemented for piping plovers and least terns (i.e., construction of Emergent Sandbar Habitat) at a level sufficient to promote persistence of the population. Supplementation of pallid sturgeon is already at Level 3, and the Intake bypass would be a Level 3 action. Figure 65 and Table 42 of the SAMP summarize the process by which actions that begin at Level 2 (e.g., IRCs, spawning habitat) can advance to Levels 3 and 4. Table 48 of the SAMP describes the process by which Level

1 observations of the correlations between flow and pallid sturgeon spawning behaviors could lead to Level 2 and Level 3 implementation of spawning flows.

Representative Quotes (Correspondence ID): 191
Comments (Comment ID): 644103

Concern Statement: The 2nd full paragraph of Section 1.4.5 (page 43) should be modified to identify locations of where IRC habitat could be located to provide the most benefit for the pallid sturgeon, which might be the Mississippi River.

Response: Analyses using advection-dispersion models have helped to determine the general location of IRCs such that embryos will have developed sufficiently to swim and forage for food; those analyses are a key reason for focusing on the portion of the Lower Missouri River downstream of Kansas City (see Figure 74 of the SAMP). Assessing the potential benefit of IRC habitats in this part of the Lower Missouri River requires actually building such habitats, and evaluating their effectiveness through a rigorous experimental design with treatment-control comparisons (a 'staircase' design). With respect to the Mississippi River, the SAMP includes Level 1 research (Appendix C) to estimate the number and survival of age-0 to juveniles hatched in the Missouri that reach the Mississippi River, relative to the number and survival of those that remain in the Missouri River.

Representative Quotes (Correspondence ID): 107
Comments (Comment ID): 644371

Concern Statement: A process needs to be developed to ensure decision criteria are developed at the earliest possible time to influence decision making, perhaps during an annual review.

Response: Decision criteria will be developed whenever an action has advanced from the general planning stage to the detailed design stage. Such decision criteria could be included as part of the annual AM report. Statistical criteria for evaluating action effectiveness are being developed as part of revisions Appendix E of the SAMP.

Representative Quotes (Correspondence ID): 107
Comments (Comment ID): 644383

Concern Statement: The Fall Science meeting should be for the Technical Teams; results can be presented/discussed with the work group and MRRIC at more appropriate meetings/formats.

Response: Considerable dialogue has occurred on these issues with the AM Governance Planning Ad Hoc Group since the Draft EIS was released. The current plan for the Fall Science Meeting will involve webinars attended by the Teams and other interested members of MRRIC.

Representative Quotes (Correspondence ID): 107
Comments (Comment ID): 644435

Concern Statement: Figure 17 of the SAMP ignores the role of the technical teams in the process and what information should be communicated with USACE leadership and MRRIC.

Response: The role of the technical teams is described further in the text that describes the process:

“The Science Update process begins when system-wide and action-specific monitoring data becomes available, along with preliminary after-action assessments. A Fall Science Meeting (see Section 2.4.3.1) is held to review initial observations from the field season, identify analytical needs with a focus on the AM workshop, and review the Strategic Plan. The Technical Team performs necessary data analysis and synthesis to evaluate action effectiveness and the habitat and species status and needs. The Team conducts any additional analyses as requested by the ISP Manager or Bird, Fish, HC, and Management Teams, and as approved by the SPM.”

Representative Quotes (Correspondence ID): 107
Comments (Comment ID): 644436

Concern Statement: While the SAMP primarily focuses on hypotheses for the recovery of three listed species, ecosystem function should be more thoroughly considered.

Response: The full suite of hypotheses considered in the Effects Analysis, as well as those prioritized for investigation in the SAMP (Table 37), consider multiple attributes of ecosystem function affecting pallid sturgeon (i.e., hydrologic connectivity, channel form, primary and secondary production, flow naturalization, rearing habitats, food availability, growth and bioenergetics, turbidity and temperature). As noted in the reviewer’s comment, the new information process can bring other hypotheses forward, such as investigations into possible explanations of poor condition (e.g., reduced carrying capacity, changes in the amount of suitable habitat following the 2011 flood, changes in prey base, intraspecific and interspecific competition, and changes in fitness).

Representative Quotes (Correspondence ID): 177
Comments (Comment ID): 644646

Concern Statement: The pallid sturgeon decision criteria presented in the SAMP should be modified to include whether additional species are listed as threatened or endangered. Any additional species could serve as criterion for evaluating the current listed species. Additionally, the decision criteria depicted in Figure 64 might also include whether there is a relationship between flow, turbidity, and food availability.

Response: If additional species are listed by USFWS then the agencies could initiate consultation on the new listed species depending on what factors might be responsible for the listing. Relationships between flow, turbidity and food availability / foraging efficiency are considered in the working hypotheses listed in Table 37 and are part of the Level 1 science investigations.

Representative Quotes (Correspondence ID): 177
Comments (Comment ID): 644648

Concern Statement: The Draft EIS allows USACE unchecked authority by permitting a broad range application of AM that goes beyond the authority established in previous adaptive management plans.

Response: The EIS does not allow USACE to have “unchecked authority.” For example, Figure 13 outlines how USACE would follow established procedures if it were necessary to consider an action outside of those evaluated in the EIS. This concept is also addressed in Chapters 2 and 4 of the EIS.

Representative Quotes (Correspondence ID): 176
Comments (Comment ID): 644765

Concern Statement: IRC metrics need to be better defined and the approach expanded to the Upper Missouri River. For those alternatives with a focus on IRC habitat, performance metrics need to be better defined. USACE should define “equivocal” and explain the range of results that would be considered positive, including whether statistical significance would be required to support additional IRC construction.

Response: The Effects Analysis developed a decision tree for the Upper Missouri population which summarizes the most critical information needs and potential actions (Figure 63 of the SAMP). Until it can be demonstrated that there is sufficient drift distance for embryos to develop into the free-swimming stage prior to entering Lake Sakakawea, it would not be appropriate to build IRCs in the Upper Missouri.

The EIS commits USACE to implementing twelve treatment-control pairs of IRCs in a staircase design over seven years, using statistical methods that are described in Section 4.2 and Appendix E.1. The EIS also commits USACE to modifying some shallow water habitat projects into IRCs. The staged development of IRCs is outlined in Table 42 of the SAMP.

Representative Quotes (Correspondence ID): 238
Comments (Comment ID): 645342

Concern Statement: Additional clarification is needed in the SAMP to describe how USACE would respond to changing implementation conditions to enable continued implementation of management actions, particularly for Alternative 2.

Response: Comment noted. Flexibility to respond to changing conditions are part of the AM Process as described in the SAMP. Without specific recommendations as to what these changing conditions might be it is difficult to respond to the comment with any detail other than stating that adopting an AM approach in itself is an indication that the agencies understand conditions can change and are open to adapt.

Representative Quotes (Correspondence ID): 242
Comments (Comment ID): 645499

Concern Statement: Droughts should be considered a major event that would occasionally be the subject of post-event investigations to update information on Human Considerations effects.

Response: Concur.

Representative Quotes (Correspondence ID): 242
Comments (Comment ID): 645586

Concern Statement: More emphasis needs to be placed on ensuring available empirical information is utilized in the process of evaluating hypotheses and development of alternatives for implementation, particularly information developed by state agencies.

Response: Science information developed through the State agencies was used and cited throughout the EA process, and information from representatives of State agencies was used in multiple expert elicitation processes. Monitoring and evaluation throughout the history of Missouri River Recovery has involved collaborations with scientists from State agencies and future efforts will necessarily continue collaborations because of the extensive scope of information needs. The Effects Analysis developed a decision tree for the Upper Missouri population which summarizes the most critical information needs and potential actions (Figure 63 of the SAMP). Uncertainty still surrounds what flow

adjustments may be needed at Fort Peck to provide favorable conditions to encourage pallid sturgeon recruitment in the Upper Basin. USACE has committed, in an amendment to the Biological Assessment, to work with USFWS and MRRIC to review previous information and information generated since the Effects Analysis to formulate test flows from Fort Peck and an AM framework for their implementation. The SAMP identifies a comprehensive framework for research to address the uncertainty regarding the effectiveness of management actions for pallid sturgeon in the upper basin.

Representative Quotes (Correspondence ID): 236
Comments (Comment ID): 645779

Concern Statement: The process should be streamlined to identify and implement management actions to mitigate USACE impacts to pallid sturgeon in the state of Montana by utilizing research results and scientific information made available by the state.

Response: USACE is supporting multiple efforts to ensure that there is no duplication of effort in pallid sturgeon research, including the Missouri River Natural Resources Conference, the Independent Science Program, and involvement of research scientists across the Basin in the Effects Analysis, as well as a broad-based elicitation of ideas for revision of the Pallid Sturgeon Population Assessment Program.

Comments (Comment ID): 646289

AMP1200 ***Adaptive Management Decision Process, Critical Engagement and Workflow***

Concern Statement: Decision making occurring during implementation of the SAMP needs to be open and transparent and should involve consultation and coordination with states' governor's offices on decisions of high consequence.

Response: Comment noted. The AM governance process is described in the SAMP including specifics regarding state involvement.

Representative Quotes (Correspondence ID): 29, 69
Comments (Comment ID): 626824, 635176

Concern Statement: There is no legal premise for implementing actions that exceed provisions of the Master Manual; any changes to the manual need appropriate review, analysis and public involvement.

Response: Attachment A.9 of the SAMP includes a description of procedures for revision of the Master Manual.

Representative Quotes (Correspondence ID): 34
Comments (Comment ID): 628333

Concern Statement: Any action implemented outside the boundaries of the ROD must go through a full NEPA analysis and public review. Likewise, any AM decision that goes beyond the scope of the Master Manual should undergo public review.

Response: Chapters 2 and 4 of the EIS discuss the process to be followed for actions outside of the ROD. Attachment A.9 of the SAMP includes a description of procedures for revision of the Master Manual.

Representative Quotes (Correspondence ID): 98, 145, 168, 228
Comments (Comment ID): 633688, 637641, 645185, 645627

Concern Statement: IRC habitat should be described and quantified to determine if there is an adequate amount of available habitat across the entire river system, not just below Kansas City. Likewise, rearing and feeding habitat for all life stages of the pallid sturgeon should be described and quantified to guide restoration efforts. The same should be done for native fish species critical to the life stages of the pallid sturgeon.

Response: The Level 3 goals for IRC development will be determined in Stage 3 of IRC development, as shown in Table 42 of the SAMP. Input from Nebraska Game and Parks Commission and other state game and fish agencies is welcome on how these goals should be determined. As described in Section 4.2.6.4 of the SAMP, the rehabilitation of SWH into IRCs will begin with an inventory of existing SWH areas, and their suitability for rehabilitation into IRCs. Figure 76 includes many projects upstream of Kansas City, which will be included in this review. Input from Nebraska Game and Parks Commission and other state game and fish agencies is also welcome as part of this review. The rationale for placing IRCs preferentially in the downstream half of the Lower Missouri River is documented in the EA and is based on prioritization of early life stage survival, among hypotheses, to explain declines in pallid sturgeon populations. The contributions of prey base and habitats used by older life stages did not emerge as a priority hypothesis, although this is subject to change as additional information becomes available (such as that contributed through the fish-condition evaluation process).

Representative Quotes (Correspondence ID): 237
Comments (Comment ID): 642913

Concern Statement: USACE needs to include “action forcing” criteria in the SAMP to ensure appropriate changes are made in a timely manner within both the scientific and administrative portions of the plan. A full suite of potential management actions should be evaluated in the Final EIS to avoid further process delays during implementation of the MRRP.

Response: The Final SAMP includes consideration of steps which can be taken to minimize process delays, while respecting established procedures (e.g., required steps for amending the Master Manual).

Representative Quotes (Correspondence ID): 183
Comments (Comment ID): 643925

Concern Statement: The events described in SAMP, Section 2.4.3.1 and Figure 18, are too prescriptive in terms of what they are and when they need to occur.

Response: We disagree. Clarity in the content and timing of events in the AM process is important. These processes have been extensively discussed with MRRIC’s Science and AM Work Group, and more recently MRRIC’s AM Governance Planning Ad Hoc Group. At the May 2017 MRRIC meeting, the group reviewed version 27 of the AM Process Diagram.

Representative Quotes (Correspondence ID): 107
Comments (Comment ID): 644437

Concern Statement: A NEPA check for decisions related to moving between pallid sturgeon implementation levels is recommended (Section 2.4.6.8, page 140 of the SAMP V6).

Response: The Final SAMP includes consideration of steps which can be taken to minimize process delays, while respecting established procedures (e.g., required steps for amending the Master Manual).

Representative Quotes (Correspondence ID): 107
Comments (Comment ID): 644438

Concern Statement: Concern expressed about moving forward with IRC construction with limited scientific information regarding potential success. A recommendation is made to move forward with just one IRC project, monitor to determine actual performance and environmental impact. Then using the adaptive management process implement the other IRC projects.

Response: The power analysis in Appendix E.1 of the Draft SAMP shows that you need at least 6 pairs of IRCs and control sites to be able to get sufficient statistical power to detect the effects of IRCs on catch per unit effort of age-0 pallid sturgeon, given the high amount of natural variability in catch per unit effort. The Draft EIS proposes 12 pairs of IRCs and control sites, so as to increase the potential biological benefits and test the feasibility of different methods for IRC construction.

Representative Quotes (Correspondence ID): 222
Comments (Comment ID): 644789

Concern Statement: Rather than committing the vast majority of MRRP budgetary resources to habitat construction, more funds should be allocated to research and monitoring to better understand species habitat requirements. Additionally, the SAMP feedback loop needs to be used.

Response: We agree that rigorous science, feedback and learning are all extremely important components of adaptive management. The annual science updates and AM workshops are meant to sharpen and accelerate the AM learning cycle. The SAMP includes a very substantial research program to assess various applied hypotheses prior to implementing certain management actions (see decision trees in Figure 63 and 64 of the SAMP). For other management actions, such as IRCs, the Effects Analysis concluded that there was sufficient evidence to support a comparative field experiment at Level 2. A rigorously designed field experiment is described in Section 4.2.6.3 of the SAMP and Appendix E.1 (i.e., staircase design of 12 IRC treatment-control pairs implemented over a 7-year period).

Representative Quotes (Correspondence ID): 197
Comments (Comment ID): 645253

Concern Statement: A question is asked regarding how potential management actions at Fort Peck and Lake Sakakawea (i.e., lake drawdown) can be mentioned and considered in any section of the SAMP when these actions were eliminated in the Draft EIS because of a high level of uncertainty.

Response: Figure 6 (page 15 of Draft SAMP, and pasted in below) shows how the range of management actions differs between the Effects Analysis, the Draft SAMP, the EIS, and the preferred alternative. The SAMP provides a broader range of actions, in case those proposed in the preferred alternative (and implemented in the ROD) prove to be insufficient for maintaining the persistence of listed species. Additional NEPA process would be required for actions outside of the preferred alternative.

Representative Quotes (Correspondence ID): 239
Comments (Comment ID): 645371

Concern Statement: Concern is expressed about the lack of provisions for actual measurement, how it will be conducted and how results will inform the decision making during implementation of the AM process.

Response: Sections 3, 4 and 5 of the SAMP describe proposed monitoring of birds, pallid sturgeon and human considerations in a great amount of detail. Further details are provided in Appendix E for pallid sturgeon, and Appendix G for birds.

Representative Quotes (Correspondence ID): 228
Comments (Comment ID): 645553

Concern Statement: AM decisions made outside the bounds of the ROD and/or conditions of the Master Manual must undergo a NEPA analysis and public review and also undergo an independent peer review of the science used to make decisions. USACE should communicate what actions are implementable using AM and make involve the public in the decision-making process. Additionally, USACE should commit to retain the two scientific panels as it is important to have the socio-economic review as part of the AM process.

Response: Responses are numbered to correspond with the points made below:

1. AM does not mean that actions are not yet identified; it means that planned actions are implemented through rigorous designs and monitoring to evaluate their effectiveness, and make necessary adjustments (or stopping them if required). Section 4 of the Draft SAMP describes a series of actions for pallid sturgeon (i.e., supplementation, intake passage, IRCs, rehabilitation of SWHs, spawning habitat, spawning flows) in considerable detail, and the associated monitoring / evaluation which would occur. Further details are provided in Appendix E. Figure 13 of the Draft SAMP describes what processes are required to implement actions of various types,

including NEPA processes, decision documents, or amendments to the Master Manual.

2. Table 40 of the SAMP describes the current status of various actions. Tables like this will be updated annually based on current information.
3. Independent socio-economic review will continue to be a part of the AM process and HC impacts will be thoroughly considered.

Representative Quotes (Correspondence ID): 228
Comments (Comment ID): 645625

Concern Statement: Concern is expressed that the adaptive management provisions laid out in the Draft EIS will result in more uncertainty for landowners with respect to the impacts of water flow management and timing of pulses that may contribute to flooding on agricultural lands. Also of concern are the Interior Drainage NED risks of Alternatives 2 and 4 as projected in the area of MRLS 575-L, some of which occur beyond the release year, as reported in the “Agriculture and Interior Drainage Environmental Consequences Analysis Technical Report.” Therefore, we request that any implemented alternative which incorporates adaptive management include provisions that maximize the amount of time between approving and implementing flow pulses and associated water level rises, particularly in the spring and early fall. This will give states and impacted residents and businesses appropriate opportunity to weigh in on implementation decisions and prepare for potential impacts.

Response: The preferred alternative in the EIS (Alternative 3) does not include any new flow actions until at least 9 years after the Record of Decision, at which time a Level 2 test of spawning flows might occur, depending on the outcomes of Level 1 research conducted over those 9 years.

Representative Quotes (Correspondence ID): 224
Comments (Comment ID): 644411

AMP1300 *Protocols and Procedures for Adaptive Management Program Implementation*

Concern Statement: Prior to implementation, any new or modified management actions which are outside the bounds of the ROD need to be the subject of through review, including public review as provided by NEPA.

Response: Figure 13 of the Draft SAMP describes what processes are required to implement actions of various types, including NEPA processes, decision documents, or amendments to the Master Manual. This concept is also discussed in Chapters 2 and 4 of the EIS.

Representative Quotes (Correspondence ID): 33
Comments (Comment ID): 628023

Concern Statement: Any changes to the SAMP which deviate from conditions of the Master Manual should require direct consultation and receipt of input from affected States. Additionally, variations in future management actions should only occur through the MRRIC approval process.

Response: Figure 13 of the Draft SAMP describes what processes are required to implement actions of various types, including NEPA processes, decision documents, or

amendments to the Master Manual. This concept is also discussed in Chapters 2 and 4 of the EIS.

Representative Quotes (Correspondence ID): 160, 185
Comments (Comment ID): 633988, 641492

Concern Statement: USACE needs to reinitiate Section 7 consultation. The SAMP needs to be based on the best available science and not the 2003 BiOp.

Response: The Effects Analysis gathered and used the best available science (since the 2003 BiOp) to develop alternatives, models and the AM actions and USACE re-initiated consultation with USFWS. The comment is in agreement with the process that was followed.

Representative Quotes (Correspondence ID): 107
Comments (Comment ID): 644288

Concern Statement: Any implemented alternative involving adaptive management and flow management should give state governments and potentially impacted businesses and residents the maximum amount of time to react.

Response: Chapter 2 of the SAMP describes the governance process that will be followed during implementation.

Representative Quotes (Correspondence ID): 224
Comments (Comment ID): 644411

Concern Statement: MRRIC team members may want to make individuals associated with the Working Group and MRRIC aware of concerns so recommendations can be made.

Response: Comment noted.

Representative Quotes (Correspondence ID): 107
Comments (Comment ID): 644439

Concern Statement: The current version of the SAMP should be archived and replaced with a more concise document that: (1) describes the hypotheses to be tested, (2) describes the monitoring program and evaluation processes to address those hypotheses, and (3) contains clearly stated goals and objectives.

Response: We acknowledge that the SAMP is a long and detailed document. That level of detail, including the appendices, is necessary for such a complex program in such a complex basin, to guide those who will be implementing the SAMP.

Representative Quotes (Correspondence ID): 107
Comments (Comment ID): 644442

Concern Statement: Implementation of the SAMP should be done in coordination and consultation with basin states, including transition from Level 1 and Level 2 actions to Level 3 and Level 4 actions.

Response: Comment noted. The comment is in agreement with the planned process as outlined in the SAMP.

Representative Quotes (Correspondence ID): 96, 197
Comments (Comment ID): 645254, 645818

Concern Statement: Continuation of independent review of the SAMP and other Program documents is encouraged as is a competitive proposal process for scientific research and monitoring efforts.

Response: We agree. The SAMP includes a continuation of the ISAP and ISETR review process for the overall program (Section 2.3.7.3), as well as internal and external reviews of proposal to the Independent Science Program, and competitive proposal processes (Section 2.5.6.5, Appendix J).

Representative Quotes (Correspondence ID): 197
Comments (Comment ID): 645267

Concern Statement: Predictive estimates should be reconciled with actual conditions prior to implementing management actions and the process to accomplish this defined in the SAMP to make appropriate adjustments accordingly to ensure species needs and human consideration implications are understood.

Response: Agreed. Empirical observations will be combined with predictive models, as well as other lines of evidence.

Representative Quotes (Correspondence ID): 159
Comments (Comment ID): 645800

Concern Statement: Information conveyed during In-Progress meetings with USACE and USFWS management should also be shared with MRRIC members.

Response: Key topics of discussion and information conveyed at in-progress meetings relating to matters of interest at MRRIC are routinely reported out at MRRIC meetings and this would continue to be the practice in the future. Due to the deliberative nature of some of the conversations not all information is ripe to be shared with the committee or is relevant.

Representative Quotes (Correspondence ID): 197

AMP2000 *Plover and Tern Monitoring*

Concern Statement: The monitoring program for the piping plover should be modified to incorporate improvements outlined in Shaffer et al. (2013) to better account for adult numbers that are claimed to be underestimated and the reported improved detection rates in other studies.

Response: Work is underway to develop an improved monitoring program for plovers and terns. This process is considering the recommendations from Schaffer et al. (2013), as well as additional modeling and statistical analyses, to develop a monitoring program that addresses management objectives while remaining cost-effective. A goal for the monitoring program is to handle uncertainty better than the existing program, either by increasing accuracy, measuring observation error so that it can be accounted for, or both.

Representative Quotes (Correspondence ID): 239
Comments (Comment ID): 642876, 645377

Concern Statement: An explanation is requested of what is meant by the statement in Table 22 of the SAMP “when navigation requirements allow.”

Response: The intent of this statement is to indicate that useful information about flow changes during the nesting season (e.g., effects on nest inundation, chick stranding, and foraging habitat) could be collected within the range of reservoir operations currently allowed for in the Master Manual. That is, if it were possible to alter flow releases such as the magnitude or rate of increases during the nesting season without affecting navigation or other factors driving summer releases, then that alteration may provide a learning opportunity. This is in contrast to changing release patterns in ways that would require changes to operating procedures or the Master Manual.

Representative Quotes (Correspondence ID): 242
Comments (Comment ID): 645559

AMP2100 *Plover and Tern Evaluation*

Concern Statement: Text should be added to the SAMP and Final EIS describing the potential implications to piping plover science related to pending results of the meta-population study.

Response: The SAMP acknowledges that metapopulation dynamics are a critical uncertainty (Sections 3.1.1.1, 3.1.2.5, 3.5.2.3). The results of the metapopulation study were still forthcoming during the development of the EIS and SAMP and so have not specifically influenced the content. However, the intent as described in the SAMP is to incorporate metapopulation information as it becomes available and to the extent possible in the plover population model. Considerable uncertainties will likely remain in this modeling unless further and ongoing investment in metapopulation research occurs. At this time, it is not anticipated that increased metapopulation understanding will alter the objective of maintaining emergent sandbar habitat acres as a primary habitat type on the Missouri River. It is anticipated that metapopulation understanding may alter the amount of emergent sandbar habitat required to meet plover population targets (increasing or decreasing habitat targets). Metapopulation understanding may also aid in interpretation of monitoring results to improve decision-making about timing and magnitude of management actions to better meet population objectives.

Comments (Comment ID): 642694

Concern Statement: The section of the SAMP dealing with bird habitat and population modeling (Section 2.4.3) should be modified to include the caveats that are listed in the document entitled Modeling to Support the Development Targets for the Piping Plover on the Missouri River (May 2015) to enable better understanding of model limitations. The section should also be modified to communicate the variability and uncertainty associated with the ESH acreage needed to meet established targets.

Response: Section 2.4.3 of the SAMP was modified to include information about modeling caveats and uncertainties with regard to ESH acreage targets.

Representative Quotes (Correspondence ID): 107
Comments (Comment ID): 643832

Concern Statement: Model verification needs to be undertaken to determine if the models are reflective of actual habitat created since the models were developed.

Response: The evaluation of ESH model performance has been provided in Fischenich et al. (2014) "Habitat Analyses for the Missouri River Effects Analysis—Geomorphic Team

Integrative Report” in Chapter 4, section Model Performance. This report has been provided as supporting material for the Draft EIS.

Representative Quotes (Correspondence ID): 107
Comments (Comment ID): 643865

Concern Statement: Additional research is needed to determine the viability of methods other than protective cages for nesting birds that do not attract predators.

Response: Research into alternative nest protection methodology was added to the list of potential studies to resolve management uncertainties about nest protection.

Representative Quotes (Correspondence ID): 242
Comments (Comment ID): 645546

AMP2200 *Plover and Tern Decisions and Planning Contingencies*

Concern Statement: Piping plover decision making criteria need to be more definitive to enable timely decision making regarding future management actions.

Response: As knowledge advances on pallid sturgeon, it will become possible to develop more decision criteria, and we agree that this is needed. The decision criteria included in the SAMP are as specific as they can be at this time.

Representative Quotes (Correspondence ID): 107
Comments (Comment ID): 643780

Concern Statement: The SAMP is rather open-ended with regard to what constitutes “enough” to avoid jeopardy. A question is asked if the “recovery-oriented” targets can be equated to non-jeopardy thresholds. The State of North Dakota also requests an opportunity to review the draft Biological Opinion before it is finalized.

Response: The targets in the SAMP are meant to avoid a jeopardy determination. There are multiple uncertainties in defining such targets, and indeed some are still to be determined. It is important that the targets are indeed sufficient to avoid a jeopardy determination, and they have been developed accordingly. Achieving the targets to avoid jeopardy will provide the foundation for subsequent decisions on how to move towards delisting of these species, and associated targets for that milestone, some of which are described in existing recovery plans.

USFWS followed its normal procedures with respect to the development of the draft and final Biological Opinion, which are described here: https://www.fws.gov/endangered/esa-library/pdf/esa_section7_handbook.pdf. However, the Draft BiOp was made available to MRRIC prior to finalization and was reviewed by the MRRIC ISAP prior to finalization.

Representative Quotes (Correspondence ID): 3
Comments (Comment ID): 645652

Concern Statement: Guidance should be developed for Section 3176 of WRDA 2007 which allows USACE to implement actions based on best available science which will avoid jeopardy for the piping plover regardless of whether or not the action is on the Mainstem of the Missouri River (e.g., off channel habitat and alkali lake habitat).

Response: USFWS has defined acceptable non-sandbar habitat as habitat which is hydrologically connected. Under the SAMP they may choose to amend this decision if

additional evidence becomes available, but it is fundamentally a decision of USFWS as to what actions address jeopardy on the Missouri River.

Representative Quotes (Correspondence ID): 3
Comments (Comment ID): 645657

Concern Statement: The Draft SAMP is oriented toward in-channel sandbar habitat and other hydrologically connected habitat for the birds and does not consider the use of off-channel habitat for bird recovery.

Response: USFWS has defined acceptable non-sandbar habitat as habitat which is hydrologically connected. Under the SAMP they may choose to amend this decision if additional evidence becomes available, but it is fundamentally a decision of USFWS as to what actions address jeopardy on the Missouri River.

Representative Quotes (Correspondence ID): 3
Comments (Comment ID): 645656

Concern Statement: Remove the reference to interior drainage as one of the authorized purposes in a statement made in the SAMP since it is not one of the authorized purposes (SAMP, page 225).

Response: This correction was made in the Final SAMP.

Comments (Comment ID): 645577

AMP3000 *Pallid Sturgeon Monitoring*

Concern Statement: The stocking of non-native sport fish and the introduction of invasive species are potential obstacles to successful recovery of the pallid sturgeon.

Response: This is a valid point, and is being considered as part of the revision of the Pallid Sturgeon Population Assessment Program, as well as potential factors affecting fish condition in the new information process.

Representative Quotes (Correspondence ID): 107
Comments (Comment ID): 643915

Concern Statement: True population studies should be undertaken as appropriate for Level 3 and Level 4 actions. Monitoring crews should assist with data gathering under Level 1 and Level 2 research actions as they overlap with Level 3 and Level 4 monitoring activities. As Level 1 and Level 2 research activities transition to Level 3 and Level 4 actions; USFWS would like to be involved in the developed of a revised pallid sturgeon monitoring program.

Response: It is proposed to monitor the population as well as monitoring the shorter-term activities. USFWS has been involved at every step of the development of this EIS, AMP, including the monitoring plans. USFWS has provided valuable input into the revision of the population monitoring program (PSPAP), as well as into the design of action effectiveness monitoring (Appendix E of the SAMP). The continued participation of USFWS in the design and revision of monitoring programs is critical to their success. Ongoing progress on the PSPAP reboot (and opportunities for comment) can be accessed here: <https://mcolvin.github.io/PSPAP-Reboot/>.

Representative Quotes (Correspondence ID): 183
Comments (Comment ID): 643943

Concern Statement: The monitoring program for pallid sturgeon should include forage fish important to the diet of the pallid sturgeon and also inclusion of telemetry technology to evaluate habitat use by the fish.

Response: Forage fish are being considered as part of the PSPAP review and revision, and investigation into fish condition. Telemetry technology is a major component of Level 1 research (see the SAMP, Appendix C).

Representative Quotes (Correspondence ID): 183
Comments (Comment ID): 643944

Concern Statement: The existing Pallid Sturgeon Population Assessment Program should be described in more detail in the SAMP and Chapter 4 of the EIS. The program should be continued and made more robust to provide a more complete accounting of what is occurring in the river and how pallid sturgeons are affected.

Response: The PSPAP, and intended improvements to it, are described in Appendix D of the SAMP. Appendix D will be updated based on current work to revise the PSPAP, as described at: <https://mcolvin.github.io/PSPAP-Reboot/>, which welcomes your input. The SAMP appendices also detail research components to increase fundamental understanding of pallid sturgeon biology (Appendix C) and robust monitoring designs for evaluating effectiveness of actions (Appendix E). Appendix D describes the collaborative population model which will be used to estimate population response. The description of the SAMP in Chapter 4 of the EIS is intended to be a higher-level description of the AM process.

Representative Quotes (Correspondence ID): 183
Comments (Comment ID): 643955

Concern Statement: The decision to only monitor for larval (non-drifting) pallid sturgeon below Kansas City is based on flow models that have not yet been validated and thus is a concern as mention is made of the observation of drifting free embryos above the Platte River.

Response: The response is mistaken about the scope of PSPAP and monitoring efforts. The reinvented PSPAP will include a range of life stages, not just larval fish, although larval fish will be emphasized in downstream segments. The larval drift models will be subject to continued validation through PSPAP sampling, IRC monitoring, and level 1 research components. The redesign of PSPAP continues to use State and Federal agencies for input. Similarly, designs of monitoring for management actions (flow cues, spawning habitat, IRCs) are being developed based on experience of State and Federal agencies and will be subject to review by those agencies.

Representative Quotes (Correspondence ID): 177
Comments (Comment ID): 644650

Concern Statement: The Final EIS and SAMP should address how long Intake monitoring will be conducted to determine if pallid sturgeon recruitment is successful before adjustments will be made to ensure project success.

Response: Detailed monitoring plans for Intake are being developed in coordination with multiple agencies and will be included as Attachment E.5 of Appendix E of the SAMP.

Representative Quotes (Correspondence ID): 242
Comments (Comment ID): 645530

Concern Statement: The Final EIS should address how an accurate pallid sturgeon population estimate can be made; and what criteria are used to make these estimates. The Final EIS should describe the level of effort and geographic scope of the pallid sturgeon monitoring.

Response: The SAMP describes the monitoring efforts required before an accurate pallid sturgeon population estimate can be made. The SAMP describes the full level of effort and geographic scope of pallid sturgeon monitoring.

Representative Quotes (Correspondence ID): 242
Comments (Comment ID): 645537

AMP3100 *Pallid Sturgeon Evaluation*

Concern Statement: A factor in the recovery of the pallid sturgeon is the need to recreate a riverine ecosystem that resembles pre-dam conditions.

Response: The focus of the MRRP is on listed species. As investigations proceed (such as those prompted by the investigation into skinny fish), we will learn more about the ecological factors that impede successful reproduction, growth and survival of pallid sturgeon, which in turn will lead to ideas about what actions are required to improve those conditions. The full suite of hypotheses considered in the Effects Analysis, as well as those prioritized for investigation in the SAMP (Table 37), consider multiple attributes of ecosystem function affecting pallid sturgeon (i.e., hydrologic connectivity, channel form, primary and secondary production, flow naturalization, rearing habitats, food availability, growth and bioenergetics, turbidity and temperature).

Representative Quotes (Correspondence ID): 131
Comments (Comment ID): 640136

Concern Statement: The SAMP is too focused on age-0 pallid sturgeon and management actions that may result in recruitment to age-1. More emphasis should be placed on other life stages due to recent evidence of poor body conditions of adult sturgeon.

Response: Indeed, all life stages are important, and this is recognized in overall conceptual model (Figure 61 in the SAMP), the redesign of the PSPAP (Appendix D of the SAMP), as well as in the detailed design of monitoring for various actions (to be included in an expanded Appendix E in the Final SAMP). The recent investigations into possible explanations of poor condition by the Effects Analysis team has led to recommendations to explore a number of alternative mechanisms (e.g., reduced carrying capacity, changes in the amount of suitable habitat following the 2011 flood, changes in prey base, intraspecific and interspecific competition, and changes in fitness).

Representative Quotes (Correspondence ID): 147, 224
Comments (Comment ID): 640690, 644408

Concern Statement: Given all the uncertainty, water quality hypotheses for the Lower River should be included as a potential explanation of why pallid sturgeons are not successfully recruiting.

Response: Water quality was considered in the hypothesis-filtering process conducted in the Effects Analysis, became one of the working set of management hypotheses (Table 5 in Jacobson et al. 2016b¹), and is thoroughly discussed in the Final Effects Analysis (Jacobson et al. 2016c²). Water quality remains a reserve hypothesis which can be activated to a higher priority if required.

Comments (Comment ID): 643829, 643923

Concern Statement: USACE should consider committing to the funding and prioritization of analysis and synthesis of monitoring data beyond annual project completion reports by sampling segment prior to the implementation of a new monitoring program.

Response: This is a good suggestion which should be considered as part of the revision of the PSPAP.

Representative Quotes (Correspondence ID): 183

Comments (Comment ID): 643945

Concern Statement: Statements in the SAMP indicating that one or more critical processes accounting for the lack of population growth in the upper basin are incorrect. Results of recent scientific studies have demonstrated that entrainment of drifting free embryos into toxic headwater habitat is the basis for the lack of natural recruitment.

Response: Progress in understanding has occurred over the last two years. The document describing working hypotheses (Jacobson et al. 2016b) summarizes workshops which occurred in 2015, and was an input to the Effects Analysis (Jacobson et al. 2016c), which evaluated the evidence for alternative hypotheses. As described in the summary of the Effects Analysis in the SAMP (Section 4.1.2.5, pg. 294) the predominant hypothesis for recruitment failure in the Upper Missouri is insufficient drift distance of embryos prior to entering the anoxic waters of Lake Sakakawea, which is consistent with the comment. We would also note that toxicity of headwaters of Lake Sakakawea has yet to be documented and accepted in peer reviewed literature; additional mechanisms for mortality may exist.

Representative Quotes (Correspondence ID): 191

Comments (Comment ID): 644060

Concern Statement: Level 1 and Level 2 actions do not meet the definition of a management action and should not be considered as such in the description of alternatives.

Response: Level 1 work are indeed studies, and we agree that they should not be described as management actions. Level 2 work involves “implementation of actions at a level

sufficient to expect a measurable biological, behavioral or physiological response in pallid sturgeon, surrogate species, or related habitat response” (Table 39, in SAMP). Such activities (e.g., construction of 12 IRC sites, construction of spawning habitat) are legitimate management actions, whether or not they are of sufficient scale to cause a population response.

Representative Quotes (Correspondence ID): 191
Comments (Comment ID): 644101

Concern Statement: A reference is needed in Tables 4 and 5 of the SAMP directing the reader to where the alternative hypotheses can be found.

Response: Section 1 is a short summary and cannot include all of the details in the rest of the SAMP. The text of Section 1.4.2 of the SAMP, which includes Tables 4 and 5, references Section 4.1.2, which summarizes the development of hypotheses in the Effects Analysis. Section 4.1.2 in turn references Jacobson et al. 2016b, which lists all of the alternative hypotheses and the prioritization process.

Representative Quotes (Correspondence ID): 107
Comments (Comment ID): 644312

Concern Statement: A hypothesis should be added to Table 5 describing the use of the Mississippi River by the pallid sturgeon.

Response: All of the working management hypotheses in Table 5 are phrased in terms of potential *management actions* which might improve the survival, growth or reproduction of pallid sturgeon; Table 5 is not a list of uncertainties. The SAMP includes hypotheses which have stimulated proposed research on the use of the Mississippi River by pallid sturgeon, as part of Big Question 4 (drift dynamics), Hypotheses 14 and 19, for the Lower Missouri River; see BQ4/L1/C5, Appendix C. This research would estimate the number and survival of age-0 to juveniles hatched in the Missouri that reach the Mississippi River, relative to the number and survival of those that remain in the Missouri River.

Representative Quotes (Correspondence ID): 107
Comments (Comment ID): 644341

Concern Statement: For the metric of catch rates on Age-2 and Age-3 pallid sturgeon associated with the sub-objective dealing with increased recruitment to Age-1 to be meaningful, other questions should be considered because of the low wild fish catch rates. Issues such as potential gear bias, or whether the correct habitats are being sampled, or are pallid sturgeon not reaching these age classes should be evaluated.

Response: These are all excellent points, and are being considered in the redesign of the PSPAP.

Representative Quotes (Correspondence ID): 177
Comments (Comment ID): 644649

Concern Statement: The SAMP would benefit from reporting other pallid sturgeon population estimates for various stretches of the lower river segments to provide a more complete range of anticipated pallid sturgeon populations below Gavins Point Dam.

Response: Agreed. This issue of spatial coverage is also being considered in the redesign of the PSPAP.

Representative Quotes (Correspondence ID): 177
Comments (Comment ID): 644651

Concern Statement: Pallid sturgeon modeling results may not be reliable if the targets for the mark-recapture monitoring efforts in the Recovery Priority Area 4 are not obtained (i.e., the established target may be unrealistic).

Response: The issue of reliability in mark-recapture estimates is being explored with the collaborative population model as part of the redesign of the PSPAP.

Representative Quotes (Correspondence ID): 177
Comments (Comment ID): 644652

Concern Statement: Concern is expressed that the management actions of Alternative 3 are not sufficient to address Big Questions 1-4 (SAMP, Table 43) and avoid a jeopardy situation.

Response: The selection of the preferred alternative involved a number of steps, which are described in Chapter 2 of the EIS. The SAMP proposes to use Level 1 field studies, not lab studies, to better understand the effects of flows on various behaviors by reproductively ready pallid sturgeon (movement, aggregation, reproduction); see Section 4.2.6.6 of the SAMP. We acknowledge in the flow evidentiary framework (Table 48 of the SAMP) that the ability to use Level 1 field studies to evaluate such hypotheses depends (in part) on the range of flow magnitudes which occur during the 9 years after the ROD. Statistical power to detect such associations also depends on the number of telemetered sturgeon that are reproductively ready and tracked; Appendix E.4 will discuss how many tagged sturgeon are required. If a sufficient range of flows do not occur, then a Level 2 test spawning flow may be implemented in the Lower Missouri River once 9 years of monitoring has occurred (see bottom of Table 48 of the SAMP).

Representative Quotes (Correspondence ID): 166
Comments (Comment ID): 644851

Concern Statement: What scientific evidence is available to support the case for inclusion of IRC as a management action to benefit survival of age-0 pallid sturgeon? What other actions were considered as there is scant mention of the benefit of channel widening in either the Effects Analysis report, Draft EIS, or SAMP?

Response: Evidence for the potential benefits of channel reconfiguration (IRCs) for the Lower Missouri River is discussed in the Effects Analysis for hypotheses 17 to 19 (Jacobson et al. 2016c, pages 112-120). The *findings* of the Effects Analysis for these hypotheses (Table 38 of the SAMP) were “Theoretical support, inference from hydrodynamic models, but data are equivocal as limiting factor and population response.” The staircase design proposed in the SAMP, with 12 IRC treatment-control pairs implemented over 7 years, is the comparative field experiment recommended in the Effects Analysis. Particle tracking models indicate that IRCs are likely to increase interception of age-0 pallid sturgeon. It is not certain that IRCs will have a statistically significant benefit in increasing the abundance, growth and survival of age-0 pallid sturgeon; the comparative field experiment included in the Draft SAMP will be able to rigorously evaluate those questions.

Representative Quotes (Correspondence ID): 245
Comments (Comment ID): 644911

Concern Statement: Support is offered for the development of IRC habitat and a request made for increasing the funding of Level 1 and Level 2 research on the effectiveness of physical habitat creation. If research results are positive, goals for the amount (acreage) of habitat creation should be increased. Additionally, research activities should be increased such that in years 9-10 there is sufficient information to determine if flow modifications are required to support pallid sturgeon recruitment.

Response: These suggestions are generally consistent with the intent of the Draft SAMP. If the first two stages of IRC development indicate that IRCs are effective, then stage 3 of IRC development (Table 42 of the SAMP) will determine the required rate of Level 3 implementation of IRCs (based on stages 1 and 2). We don't know now how many acres per mile would be required to benefit the population. The issues related to evaluating the need for spawning flows are discussed in response to several other comments.

Representative Quotes (Correspondence ID): 206
Comments (Comment ID): 645130

Concern Statement: More communication with MRRIC and the general public regarding the IRC concept should occur.

Response: This is a good suggestion, and will be considered for future MRRIC meetings. The fact sheets developed for IRCs (and other topics) are one step in improved communication, which MRRIC members can use when speaking to the people they represent (<http://moriverrecovery.usace.army.mil/mrrp/f?p=136:70#FactSheets>).

Representative Quotes (Correspondence ID): 242
Comments (Comment ID): 645514

Concern Statement: The stated goal of increasing pallid sturgeon recruitment to age-1 is too simplistic to understand the mechanisms behind the metric and should be augmented with sub-metrics (e.g., prey species abundance, competitor abundance, types of substrate and habitat, and other factors considered important in the conceptual models).

Response: These suggestions will be considered as part of the revision of the PSPAP, as well as in development of monitoring plans to assess the effectiveness of actions, which will be described in Appendix E. Substrate and habitat are part of the monitoring plans for several actions (Intake bypass, spawning habitat development, IRCs, rehabilitation of shallow water habitat into IRCs). The abundance of prey species is under consideration for the revised PSPAP, and also as part of the investigations into poor fish condition. Investments in monitoring do involve tradeoffs between breadth and depth of coverage.

Representative Quotes (Correspondence ID): 238
Comments (Comment ID): 645322

Concern Statement: A decision tree should be created highlighting the future operational changes that might need to occur if spawning cue releases are demonstrated to benefit pallid sturgeon recruitment. A scenario analysis should be undertaken with decision criteria and performance metrics developed to communicate under what conditions flow modifications would occur.

Response: Table 49 of the SAMP provides the proposed rules for spawning flow releases. It seems that what is being requested is an analysis to determine how often such releases would occur based on historical water years. The HEC-RESSIM and HEC-RAS runs from alternative 2 codified the conditional rules so the results should in theory address

and incorporate this concern. That information may already exist in the HydroViz tool. We will consider this suggestion in revisions to the Draft SAMP.

Representative Quotes (Correspondence ID): 238
Comments (Comment ID): 645334

Concern Statement: Management actions should be developed and implemented to enhance habitat conditions for important prey species, especially within tributaries and side channels of the Missouri River.

Response: We will consider these suggestions as the AM program is implemented. The geographic scope of the MRRP, as currently defined in Section 4.1.1.1 of the Draft SAMP, does not include tributaries, other than the Yellowstone River. This scope does not however preclude efforts by USACE to coordinate with other entities involved in developing actions on tributaries. At present prey species populations are not considered a priority hypothesis; the EA hypothesis filtering and conceptual ecological model reports document that carrying capacity issues presently have equivocal science support. This could change as the fish-condition question evolves.

Representative Quotes (Correspondence ID): 238
Comments (Comment ID): 645336

Concern Statement: A transplant experiment at the Yellowstone Intake could result in harming pallid sturgeon during transport.

Response: This is a wise precaution, and all efforts will be made to ensure that stress is minimized. In preparation for a pilot implementation of the translocation experiment in 2017, the study plan addressed this concern with procedures to minimize stress, handling, and transport distance. All handling of the fish followed the established pallid sturgeon fish-handling protocol. U.S. Fish and Wildlife Service, 2012, Biological procedures and protocols for researchers and managers handling pallid sturgeon: U.S. Fish and Wildlife Service, 40 p.

Representative Quotes (Correspondence ID): 242
Comments (Comment ID): 645529

Concern Statement: The fitness of adult pallid sturgeon needs further examination as condition concerns of adult fish could hinder successful recruitment. Additional research is recommended to verify condition concerns and determine what can be done to improve the health and productivity of adult sturgeon.

Response: The comment is valid and is being addressed. Concerns about fish condition raised by the Nebraska Game and Parks Commission led to an investigation by the Effects Analysis team, as described in the SAMP. The EA team has recommended several lines of research into the potential causes of poor fish condition in some segments of the Missouri River, including reduced carrying capacity, changes in the amount of suitable habitat following the 2011 flood, changes in prey base, intraspecific and interspecific competition, and changes in fitness.

Representative Quotes (Correspondence ID): 242
Comments (Comment ID): 645533

Concern Statement: Available SWH sites are not sufficient to support pallid sturgeon spawning activities because virtually no documented spawning or recruitment success has been

recorded. Enhanced or restored spawning habitat should be in place prior to any flow test to determine if the flow release will be sufficient for pallid sturgeon.

Response: USGS studies have documented spawning in many areas in the Lower Missouri River (DeLonay, A.J., Chojnacki, K.A., Jacobson, R.B., Albers, J.L., Braaten, P.J., Bulliner, E.A., Elliott, C.M., Erwin, S.O., Fuller, D.B., Haas, J.D., Ladd, H.L.A., Mestl, G.E., Papoulias, D.M., and Wildhaber, M.L., 2016, Ecological requirements for pallid sturgeon reproduction and recruitment in the Missouri River: A synthesis of science, 2005-2012: U.S. Geological Survey Scientific Investigations Report 2015-5145, 224 p., [Also available at <http://dx.doi.org/10.3133/sir20155145>].) and this information has been compiled in the EA reports, notably the integrated report (Jacobson, R.B., Annis, M.L., Colvin, M.E., James, D., Welker, T.L., and Parsley, M.J., 2016, Missouri River Scaphirhynchus albus (Pallid Sturgeon) Effects Analysis—Integrative Report 2016: U.S. Geological Survey Scientific Investigations Report 2016-5064, 154 p., [Also available at <http://dx.doi.org/10.3133/sir20165064>].) This information establishes that spawning is relatively common – measured as egg release. What is not known is whether eggs are fertilized, incubated, and hatched successfully. Engineered spawning habitat will be in place prior to any test of spawning cue flows. However, fish behavioral responses to migrate and aggregate in response to a flow pulse will provide valuable information about the role of flow pulses even if the fish do not find optimal spawning habitat. As described in Table 42 of the SAMP, spawning habitat is required to be in place within 2 years of the Record of Decision, whereas a Level 2 test of spawning flows (if implemented, depends on evidence summarized in Table 48 would not occur until at least 9 years after the ROD.

Representative Quotes (Correspondence ID): 242
Comments (Comment ID): 645544

Concern Statement: Competition from non-native fish species needs to be evaluated and included in the SAMP for pallid sturgeon.

Response: Competition from non-native fish species including Asian Carp is not currently a priority hypothesis but could be introduced into the process at a later date should it be determined that pallid sturgeon are food limited.

Representative Quotes (Correspondence ID): 107
Comments (Comment ID): 645822

Concern Statement: Discussion of the Pallid Sturgeon Population Augmentation Program should focus on the quality of stocked fish rather than quantity. Quality of stocked fish should be identified as a limiting factor and include physiological and ecological factors, such as overall health of fish when stocked and ability to adapt to natural river conditions (e.g., feeding).

Response: Quality of stocked fish is one of the many potential indicators being considered as part of the redesign of the PSPAP.

Representative Quotes (Correspondence ID): 245
Comments (Comment ID): 644916

Concern Statement: The wild pallid sturgeon population is aging and there is not sufficient time to wait ten years to conduct the one-time spawning cue test. Additionally, this test needs to be repeated to provide meaningful data.

Response: It will be very important to learn as much as possible during the 9-year period after the ROD. Revisions are being made to Appendix E to explore how to maximize learning during this period. Table 48 of the Draft SAMP (page 393) describes the process by which Level 1 observations of the correlations between flow and pallid sturgeon spawning behaviors could lead to Level 2 and Level 3 implementation of spawning flows, including the possibility (if required) of implementing such flows once every three years. We acknowledge in Table 48 and the associated text that the ability to use Level 1 field studies to evaluate such correlations depends (in part) on the range of flow magnitudes which occur during the 9 years after the ROD. Statistical power to detect such associations also depends on the number of telemetered sturgeon that are reproductively ready and tracked; Appendix E.4 will discuss how many tagged sturgeon are required.

Representative Quotes (Correspondence ID): 179
Comments (Comment ID): 645233

AMP3200 *Pallid Sturgeon Decisions and Planning Contingencies*

Concern Statement: USACE should make a commitment in the Draft EIS and the SAMP to implement appropriate Level 3 and 4 management actions (in Montana specifically) following research conducted during Level 1 and 2 actions and evaluation of new scientific information.

Response: Modifications at Fort Peck Dam were considered during alternatives formulation. Please see Section 2.5.21 of the Final EIS for a detailed discussion of the status of actions at Fort Peck Dam. In recognition of the scientific uncertainty surrounding Fort Peck flow adjustments, USACE agreed to formulate test flows from Fort Peck and an AM framework for their implementation during formal ESA Section 7 consultation on this plan. Studies under the framework may include additional drift studies, tracking of fish and documentation of spawning locations, telemetry evaluations and methodology improvements, risk analysis, and engineering studies. Implementation of an identified hydrograph to test hypotheses would be considered; however, depending on the specifics of the test hydrograph, may be outside the scope of this EIS.

Representative Quotes (Correspondence ID): 191
Comments (Comment ID): 644102

Concern Statement: Assessment of impacts to Missouri River fish communities as a result of reliance on short-term science projects to test specific hypotheses of fish species interactions will not be sufficient to properly assess predicted impacts of management action implementation to fish communities as a whole.

Response: There is indeed a tradeoff between investigations into the factors limiting the reproduction, growth and survival of pallid sturgeon (the focus of the MRRP), versus a comprehensive study of the entire fish community.

Representative Quotes (Correspondence ID): 177
Comments (Comment ID): 644653

Concern Statement: A timeline for movement of an average management action from Level 1 to Level 4 should be provided.

Response: The current timelines for completion of Level 1 and Level 2 studies are summarized in Figure 81 of the SAMP. Evaluations of the potential implementation of some Level 3

actions (e.g., spawning habitat, spawning flows) would occur following completion of Level 1 and Level 2 work. The timeline for moving IRC work from Level 2 to Level 3 (if Level 2 tests are successful) would be 7 years after the ROD, and for moving from Level 3 to Level 4 (if Level 3 tests are successful) would be 10 years after the ROD, as described in Table 42 of the SAMP. Both supplementation and the Intake bypass are Level 3 actions.

The time limits for the Level 3 implementation in the framework are not inflexible, but are also not arbitrary – they generally reflect an estimate of the time required to execute underpinning Level 1 and 2 studies, represent a point in time when field study using AM is needed to advance understanding on a key uncertainty, or were identified in deliberations between USACE and USFWS because they provide necessary assurances/commitments on the part of USACE to take action should the science remain equivocal.

Concern Statement: What research/monitoring activities are proposed to address concerns about the hybridization of pallid and shovelnose sturgeons?

Response: Hybridization is indeed a concern, and is discussed in the SAMP (e.g., in Section 4.1.2.4: “Spawning habitats should be designed to reduce (not increase) hybridization of pallid and shovelnose sturgeon. Trends in hybridization over time should be tracked, so that they don’t confound field and model based estimates of the effects of various management actions.”). Genetics research currently under way by Dr. Edward Heist (S. Illinois University) and USGS is advancing the ability to use genetic algorithms to distinguish pallid sturgeon from shovelnose sturgeon, and this work (which found more hybridization in the Lower Missouri, and little in the Upper Missouri) has implications for stocking strategies. See abstracts from 2017 Missouri River National Resources Conference at [http://mrnrc2017.com/2017%20Presentation%20Abstracts\[48710\].pdf](http://mrnrc2017.com/2017%20Presentation%20Abstracts[48710].pdf).

Comments (Comment ID): 645541

Concern Statement: Research should be conducted to determine if the velocity and turbulence experienced in the navigation channel is detrimental to free embryos of pallid sturgeon within the lower portions of the river.

Response: Level 1 research (BQ4/L1/C2) has been planned to address this question. See text in Appendix C, which describes research in experimental flumes, relevant to Big Question 4 on Drift Dynamics:

“The objective of this screening component is to characterize how resilient pallid sturgeon free embryos are to hydraulic conditions, particularly turbulent energy. If embryos are fragile, flow modifications, such as increased flow during spawning periods may increase embryo mortality. If embryos are found to be susceptible to mortality due to physical disturbance imparted by velocity or turbulence, flow regimes may be modified to minimize embryo mortality.”

Representative Quotes (Correspondence ID): 242
Comments (Comment ID): 645552

Concern Statement: More emphasis should be placed on pallid sturgeon habitat creation and associated research.

Response: The Draft SAMP includes the creation of IRC habitats and spawning habitat, as well much associated research.

AMP4000 *Human Considerations Adaptive Management*

Concern Statement: Recommendation to continue with two MRRIC independent scientific review panels, especially the Independent Socio-economic Technical Review Panel to ensure a more socio-economic focus is maintained.

Response: This issue is addressed in response to comment 644432.

Representative Quotes (Correspondence ID): 197
Comments (Comment ID): 645268

Concern Statement: Adaptive management processes should be developed and implemented to review socioeconomic data and make appropriate adjustments to management actions as new information regarding impacts to social and economic resources is made available.

Response: Concur. AM related to human considerations is described in Section 5 of the Draft SAMP.

Representative Quotes (Correspondence ID): 228
Comments (Comment ID): 646296, 646298

Concern Statement: Greater specificity regarding human considerations monitoring needs to be integrated into SAMP Section 5.0.

Response: Additional specificity has been added and is reflected in Chapter 5 of the Final SAMP.

Representative Quotes (Correspondence ID): 3
Comments (Comment ID): 645658

Concern Statement: Additional clarification is required regarding a statement in the SAMP (Section 5.8.3.9, page 488) addressing decision making for human considerations during a proposed flow release: Revise the following sentence for clarity. “The case of a sudden, acute HC issue that might preclude the use of a flow release in season...would be raised directly at the Management Team level at the discretion of the USACE.” For example, does this mean USACE’s Missouri River Basin Water Management Division has discretion to preclude a flow release due the possibility of exceeding an established threshold?

Response: A description of the Water Management communication process and schedule is provided in the SAMP.

Representative Quotes (Correspondence ID): 3
Comments (Comment ID): 645664

Concern Statement: Thresholds that could be used to avoid and/or mitigate impacts of a spring flow release (e.g., improved weather forecasting, snowpack conditions, local

precipitation events, presence of ice in the river, etc.) should be established and discussed more explicitly in the Final EIS and SAMP.

Response: The Final EIS contains a description of the types of considerations for mitigating impacts of one-time test releases in Chapter 2.

Representative Quotes (Correspondence ID): 3

Comments (Comment ID): 645663

Concern Statement: Establishing thresholds for flow management activities to avoid cascading effects to human considerations for an extended period of time is important to protect those resources for which the state is responsible for managing. Establishment of the thresholds should be coordinated with the states.

Response: The Final EIS contains a description of the types of considerations for mitigating impacts of one-time test releases in Chapter 2.

Representative Quotes (Correspondence ID): 3

Comments (Comment ID): 645660

Concern Statement: Implementation of the adaptive management process would benefit from consultation with state agency experts regarding how to avoid adverse effects to human considerations, particularly as it relates to flow management changes on the Missouri River.

Response: States are free to join the Human Considerations team which is a collaborative MRRIC group that will track impacts to human considerations. Additionally, each site-specific project will involve state coordination and compliance with all applicable state laws and regulations.

Representative Quotes (Correspondence ID): 3

Comments (Comment ID): 645659

Concern Statement: The SAMP governance structure places too much emphasis on the three listed species and insufficient emphasis on human considerations.

Response: The governance structure is balanced with respect to birds, fish and human considerations, and has been developed collaboratively with MRRIC.

Comments (Comment ID): 645665

AMP6000 Effects Analysis in Relation to AM

Concern Statement: The need for increased sediment load within the riverine system should be factored into hypotheses addressing life cycle needs of the pallid sturgeon.

Response: Sediment augmentation is considered in Big Questions 4 for the Upper Missouri River, and the associated hypothesis 6, as described in Table 43 of the Draft SAMP and in Appendix C of the SAMP.

Representative Quotes (Correspondence ID): 34
Comments (Comment ID): 628340

Concern Statement: What are the hydrological conditions represented by Hamburg and Lisbon-Jameson bends that make these best suited for pallid sturgeon. Additionally, the best condition for pallid sturgeon larval growth may be on the Mississippi River.

Response: The EA was careful to state that the Hamburg and Lisbon Bends were used as best *available* conditions, not optimal. The interpretation on best available is by comparison with historical measures of channel complexity and availability of shallow, slow water. These sites have more complexity, more variability, and are more like historical conditions. Some relevant information is available in: Jacobson, R.B., and Galat, D.L., 2006, Flow and form in rehabilitation of large-river ecosystems: An example from the Lower Missouri River: Geomorphology, v. 77, no. 3-4, p. 249–269, [Also available at <http://dx.doi.org/10.1016/j.geomorph.2006.01.014>]. And Jacobson, R.B., Johnson III, H.E., and Dietsch, B.J., 2009, Hydrodynamic Simulations of Physical Aquatic Habitat Availability for Pallid Sturgeon in the Lower Missouri River, at Yankton, South Dakota, Kenslers Bend, Nebraska, Little Sioux, Iowa, and Miami, Missouri, 2006-07: 2009-5058, [Also available at <http://pubs.er.usgs.gov/publication/sir20095058>], and cited references.

Representative Quotes (Correspondence ID): 107
Comments (Comment ID): 643838

Concern Statement: Sediment bypass below Gavins Point Dam should be added to Section 1.4.2 and Table 4 within the umbrella question and related hypothesis.

Response: Sediment bypass did not receive priority ranking for downstream of Gavins Point Dam during the expert-based filtering process; it remains in the conceptual ecological models and the reserve hypotheses Jacobson, R.B., Parsley, M.J., Annis, M.L., Colvin, M.E., Welker, T.L., and James, D.A., 2015, Development of conceptual ecological models linking management of the Missouri River to pallid sturgeon population dynamics: U.S. Geological Survey Open-File Report 2015-1038, 47 p., [Also available at <http://dx.doi.org/10.3133/ofr20151038>]. Jacobson, R.B., Parsley, M.J., Annis, M.L., Colvin, M.E., Welker, T.L., and James, D.A., 2016, Development of working hypotheses linking management of the Missouri River to population dynamics of Scaphirhynchus albus (pallid sturgeon): U.S. Geological Survey Open-file Report 2015-1236, 33 p., [Also available at <http://dx.doi.org/10.3133/ofr20151236>]. The rationale was that sediment for bedload or suspended load did not seem to be limiting (for benthic habitat or for turbidity) in most of the Lower Missouri River, at least downstream of the Big Sioux River. Moreover, calculations of annual sediment loads have shown that the annual load to Lewis and Clark Lake would be a small percentage of the historical load at Yankton (Jacobson, R.B., Blevins, D.W., and Bitner, C.J., 2009, Sediment regime constraints on river restoration: An example from the Lower Missouri River: The Geological Society of American -Special Paper, v. 451, [Also available at <http://specialpapers.gsapubs.org/content/451/1.short>].) A different case could be made for the importance of sediment bypass for emergent sandbar habitats for terns and plovers.

HHTR300 *Hydrology and Hydraulics Technical Report - HEC-ResSim Alternatives*

Concern Statement: Using Garrison Dam as an example, steady releases (for the purposes of not flooding nested birds) would be implemented from May 15 to August 31 as long as the elevation of Lake Sakakawea was between 1,790.6 feet and 1,850 ft. The navigation system storage preclude is defined in the Master Manual as 31 MAF. This equates to an elevation of 1,795 feet on Lake Sakakawea. Elevation at 1,850 feet is the top of the annual flood control zone. It is understood that criteria had to be chosen to simulate reservoir operations, however, operating the system in this fashion puts less emphasis on mitigating floods and drought conditions, and more emphasis on endangered bird species.

Response: In real-time operations, Garrison releases are attempted to remain constant during the summer nesting season to the extent reasonably possible in an attempt to balance the authorized purposes. The decision to increase/decrease releases is made by

Missouri River Basin Water Management on a case-by-case basis. During the calibration of the ResSim model, the listed elevations were used to mimic the decision of when to increase/decrease releases.

Comments (Comment ID): 645697

RTT100 *Recreation Technical Report: General Comments*

Concern Statement: The recreation evaluation used the unit day value approach, which considers boating recreation as part of the general recreation category, and as a result, there are lower UDV's for boating visitation. Since most of the boating recreation on the upper five reservoirs is also engaged in fishing, the lower UDV is not appropriate. This simplified UDV approach is acceptable for comparing alternatives, but the RED valuation method based on expenditure data should be used when comparing recreation with other interest categories.

Response: The Final EIS recreation evaluation was updated to use a hybrid method to estimate the recreation consumer surplus values based on both the Unit Day Value (UDV) and the travel cost method (TCM) approaches. The UDV method of estimating willingness to pay relies on expert and informed opinion to assign relative values to recreation days based on the quality of recreational opportunities supported by individual recreation areas. The TCM is a revealed preference method of economic valuation that deduces willingness to pay through observing human behavior (i.e., the number and trips and costs per trip to a recreation area). The approach to estimate the consumer surplus recreation values uses the UDV, which is based on USACE guidance and site-specific ratings and activities, but also recognizes that the UDV may reflect a relatively lower estimate of the consumer surplus value for a recreation visitor-day. The UDV guidance (USACE 2017) indicates that the general category should comprise activities such as swimming, picnicking, and boating. However, based on professional judgment and a review of other studies (Loomis 2005; USACE 2002), boating on the river and reservoirs was allocated to a specialized recreation category with a relatively higher value per day than the general recreation activities. The UDV (in 2018\$) was estimated and then proportionally increased based on the difference between the UDV and TCM as estimated in the Recreation Economics Volume 6C of the Master Water Control Manual Missouri River Review and Update (USACE 1994). The "Recreation Environmental Consequences Analysis Technical Report" Section 2.4.3 describes the approaches used to estimate the consumer surplus value of a recreation visitor day.

We have considered the NED, RED, and OSE accounts in the impact assessment. The NED and RED impacts address different topics. The NED and RED results are not used to compare across interests but assess the tradeoffs across the alternatives. The NED looks at the interest for the nation, and the RED analysis has different regions for analysis. The RED results across interests cannot be aggregated and compared because the boundaries are different among the interests and topics.

WSTR100 *Water Supply Technical Report: General Comments*

Concern Statement: The water supply analysis appears to underestimate the size of pumps needed to service intakes when water surface elevations fall below operating conditions. The analysis also does not consider the difficulty of locating and renting pumps in a timely fashion especially if multiple jurisdictions needed pumps of similar size. In addition, not all low water conditions could be solved using submersible pumps. In some cases, utilities may have to lay miles of pipe just to reach the source water. Also, the river channel could migrate away from the intake. The costs of these impacts (other than submersible pumps) need to be considered in the analysis.

Response: The water supply analysis utilized information to match pump size and capacity with intake pumping capacity to determine the size and number of pumps needed to mitigate issues when flows fall below intake operating conditions. Because the management plan alternatives represent a short-term increase in the number of days that flows would fall below operating conditions, the project team applied one approach water supply operators could use to mitigate these type of short term impacts. The project team did some additional research on the use of submersible pumps as credible approach to address short-term, temporary impacts when water surface elevations fall below operating thresholds. There is evidence that intake managers, both small and large have used the approach, either currently or in the past, to address the type of impacts that are modeled under the MRRMP alternatives. While this approach may not be the one that would be used by water supply managers in all cases, there is enough evidence that it may be one approach that would be considered. The project team felt applying this approach for all alternatives provides a way to compare impacts that may occur under the different alternatives which is the objective of the analysis. While applying other approaches may bring the analysis closer to what may happen under actual conditions, including these other measures would not change the ranking of the alternatives. In addition, further analysis of the impact the MRRMP alternatives may have on stages was conducted and described in the “Water Supply Environmental Consequences Analysis Technical Report” in Section 3.1. The analysis showed that stage levels were not impacted under the management alternatives and would not require intake modification beyond what would occur under Alternative 1.

Representative Quotes (Correspondence ID): 32, 38
Comments (Comment ID): 627964

Concern Statement: The frequency of low flow occurrences and the associated costs with mitigating these conditions should be included in the analysis.

Response: The project team provided additional detail on the frequency and season of low flow occurrences under the management plan alternatives in the technical report. Due to privacy concerns, this information is only available upon request from individual water supply operators.

Comments (Comment ID): 628464

HTR100 *Hydropower Technical Report: General Comments*

Concern Statement: The lack of modeling of the spring sturgeon pulse for Alternatives 3–6 results in errors in the analysis for hydropower. Alternatives 1, 4, and 5 do not use the same operational base.

Response: The description included in this section is intended to describe the alternatives generally and describes Alternatives 4 and 5 as similar to Alternative 1, but it is not meant to imply that those alternatives are using different operational bases than the other alternatives. Alternative 1 is the alternative against which the other alternatives are being compared. The final “Hydropower Environmental Consequences Analysis Technical Report” will include an updated and clarified description of the alternatives analyzed.

Comments (Comment ID): 644257

HHTR200 *Hydrology and Hydraulics Technical Report - Period of Record Development*

Concern Statement: It is not clear how evaporation was accounted for in the HEC-ResSim model. The data in the report is not consistent with the evaporation plots for Lake Oahe in the Missouri River Mainstem HEC-ResSim Modeling – Mainstem Missouri River Reservoir Simulation Report.

Response: The data in Missouri River Mainstem HEC-ResSim Modeling - Mainstem Missouri River Reservoir Simulation Report is what was used in the ResSim modeling. The figures and text in the Time Series Data Development for Hydrologic Modeling Report will be updated to reflect the text and data in the Simulation Report.

Representative Quotes (Correspondence ID): 1
Comments (Comment ID): 645696

HEC100 *HEC-ResSim Modeling Report: General Comments*

Concern Statement: The MRRMP-EIS should provide further review of hourly flows, incorporate discussion on potentially impacting low flows, and consider impacts in the evaluation of alternatives.

Response: In real-time operations, the Mainstem projects have standing orders issued by Missouri River Basin Water Management that specifies a minimum hourly flow/energy for a set amount of time, which limits the peaking when releases are low. This is done to limit the stage fluctuations in the river reaches, which reduces impacts to intakes. Using a daily average to estimate impacts to intakes should be adequate since there would not be much stage fluctuations at low flows.

Representative Quotes (Correspondence ID): 167
Comments (Comment ID): 643866

Concern Statement: Updates provided on intake elevations at the Heskett Plant should be physically confirmed with the model inputs and confirm that the low flow elevations the model is projecting are accurate when compared with the elevations provided by facility owners for low flow event impacts.

Response: For the portion of the comment pertaining to the RAS model:

HEC-RAS model geometry is based on the best available topographic surveys. All constructed models were calibrated to the same period through 2012. Calibration accuracy within this reach varies by location but is generally within 0.5- to 1-foot accuracy for normal and low flows. Model calibration within the Garrison to Oahe reach

is discussed in the supporting documents, HEC-RAS Calibration Report, which is available online (www.moriverrecovery.org).

The Missouri River is a dynamic system that is changing constantly over the study area, which extend from Ft. Peck dam downstream to the Missouri River mouth at St. Louis. Some areas have experienced continued degradation since 2012 while other areas have experienced aggradation. Regardless, all alternatives were modeled with HEC-RAS using the same geometry and the comparison between the Alternatives is valid.

Local effects on stage due to temporary changes in river conditions, including ice jams, ice cover, and transient sandbar dynamics, are not included within the HEC-RAS model. These temporary effects often cause river stage changes of several feet. However, for the purposes of alternative comparison, including transient effects is not relevant (e.g., the formation of an ice jam has the same effect on all alternatives). The EIS methodology employs an 82-year period of record with current water development conditions to evaluate differences between alternatives. Use of the extensive 82-year period allows for reasonable alternative impact evaluation for a wide range of flow events.

Representative Quotes (Correspondence ID): 167
Comments (Comment ID): 643848

Concern Statement: Use of the 2012 channel geometry to evaluate the impacts of the alternatives has not been proven accurate at low flows at Heskett intake. It appears that the model does not take into account channel changes since the survey was conducted, as well as Oahe Lake effects, within the river reach near Heskett and channel siltation. There is also concern that actual elevations at Heskett intake were not confirmed at the time of the 2012 survey. USACE should confirm whether the model corresponds to flow and elevations outside of the 2012 survey timeframe and make model adjustments accordingly to demonstrate accurate predictions. Additionally, USACE should consider evaluating this for all affected water users and review the model accuracy to consider the consequences of multiple stations along the Missouri River being affected by low releases.

Response: For the portion of the comment pertaining to the RAS model:

HEC-RAS model geometry is based on the best available topographic surveys. All constructed models were calibrated to the same period through 2012. Calibration accuracy within this reach varies by location but is generally within 0.5- to 1-foot accuracy for normal and low flows. Model calibration within the Garrison to Oahe reach is discussed in the supporting documents, HEC-RAS Calibration Report, which is available online (www.moriverrecovery.org).

The Missouri River is a dynamic system that is changing constantly over the study area, which extend from Ft. Peck dam downstream to the Missouri River mouth at St. Louis. Correspondence Text

It is of grave concern for the entirety of the Missouri River Valley that I write this note regarding the Army Corps of Engineers proposed changes for the Missouri River to aid in the propagation of the pallid sturgeon and any other Endangered Species by increasing the length or intensity of flow events. ANY increase in the flood constraints by the corps will have lasting and compounding effects to all users of the great Missouri River. There should be no change in regards to the length or intensity of flow events or pulses by the Corps. If changes are made that could very well result in the reduction and/or elimination of thousands of acres of agriculture lands. In addition, some levee districts do not have the ability to pump water, increasing the flood constraints will increase the susceptibility to flooding that those areas will face. The river changes greatly with rainstorm events in very short periods of time as it is, if the length or intensity of flow events increases, and then a rainstorm event happens there will not be any where for the water to go but to flood communities and farm grounds in its path.

The river should be managed for these priorities:

- #1 Flood Control
- #2 Consumption; domestic use and irrigation
- #3 Navigation

Correspondence Text

The river should be managed for:
#1 Flood Control
#2 Consumption; domestic use and irrigation
#3 Recreation
#4 Navigation

Managing for endangered species should not supersede the other uses and commitments made when the dams were built.

In the Table 3-211 on Page 3-465, the four power plants located from river mile 532.6 to 645.9 should be moved up so they are listed under the "Gavins Point Dam to Rulo" heading for river reach.

Sir, I would be interested in placing my support with Alternative 5, that increases autumn flows supporting migrating waterfowl. It is sad to have such a beautiful resource so close, but to be so short sighted about it's potential for recreational use. Thank you.

Correspondence Text

Why don't you try having the public meeting on a day that people will come. Nice try having it on Valentines day! How stupid do you think people are? I am so sick of hearing about the piping plover. I don't care anymore about that then you people do for flooding peoples farms. Maybe you shouldn't be planning your next disaster until you go to court over the last one.

One thing that might help these animals you care about so much is cleaning up the Desoto refuge from all the debris that floated in during the flood. Our property sits next to it and we hauled 3 tons of metal salvage, 1 of aluminum, tons of trash and still cleaning up the dead trees. No one seems worried about the animals there. They were to busy suing an elderly man for growing a row of asparagus down by Boyer Chute. You people need to get your priorities straight and start thinking about how you impact human lives.

Below where it asks how I heard of this document you need to have pissed off people as one of your selection options.

Good Afternoon,
I am Scott Albers and work for Nor-Am Cold Storage in St Joseph, MO. We are a Public Refrigerated Warehousing company and have facilities in the Stockyards Industrial area of St Joe. We want to voice our concern over the changing in priorities regarding the flows/levels of the Missouri River. We love wildlife, but not at the expense of our employees, customers and property. These are some of the facts for a small family owned company.
90 employees in St Joe
\$20m investment in facilities
In the flood of 2011 we incurred well over \$300k in flood fight costs and our employees lost wages. We also risk the Rosecrans Airport and the Air Guard wing that is housed there. The airbase has a significant economic impact \$160m annually for St Joe surrounding area. We can not afford to lose the base due to flooding and permanently moving. We need to protect this area and can not have endangered species trump human well being when we are talking the levels of the Missouri River.

If you wish to discuss further please don't hesitate to call me directly.
Thank you for your consideration.

I own property at Big Lake, Missouri and was negatively impacted by previous planned flooding of this area in 2011 and prior years. The intentional actions of the Corp. caused extreme economic hardship to many people in Holt County, Missouri. Therefore, I object to any actions by the Corp which would cause intentional flooding in this area.

Acknowledge speakers and sign in today. Hearing on 2/8/17. Verbal written statements. Send second Tittle to all tribes.
You can not flood our lives! Or buy it.
You/we need more time than April 24th.
You need to come to community/reservation to discuss, etc.
You have money for travel. We don't!
What are you doing about Trump abolishing the NEIPA process?
Why isn't catastrophies includes, etc.
This is only a few questions.

- 1) More emphasis on Tribal Consultations. Tribal cultural property surveys need to be done as well as archeological surveys
- 2) "Rip-rapping" of Tribal areas to preserve 1620 line.
- 3) Actual consideration of Tribal interest. Not leading the tribes on like you are willing to work with us, then choosing to do nothing to help conserve our lands
- 4) Understanding that cultural interests are just as important as the 3 endangered species when it comes to the environment. The environment shapes the traditions of the people living within it. Remember this please.
- 5) Socio-economic is not just statistics, formulas, and numbers, it is people. How thoroughly have you considered impacts to people? Stop assuming. Go right to the source.
- 6) How will spring/fall pulse affect the intake systems with silt increases and inundation?
- 7) Who are the 29 stakeholders?
- 8) 29 tribes have a right to consultation. Please fix this.

After review of the alternatives presented, I can not support any option. I find the Fish and Wildlife Service is asking the USACE to abandon priorities of flood control, navigation, and water supply availability to do the management experimentation of the FWS.
USACE responsibility to not unnecessarily damage threatened species do not present the responsibility to save all endangered species at the peril to other responsibilities.
Thank you for this opportunity to comment.

Dear HQ, United States Army Corp of Engineers:

AgriVision Equipment Group, LLC is a John Deere agricultural dealership with 10 locations serving customers in Iowa, Nebraska, and Missouri. Two of these locations are in the Missouri River valley and are located along I-29 near Pacific Junction and Hamburg, Iowa. The history of AgriVision Equipment serving customers along the Missouri River dates back to more than 75 years when the Athen family purchased the John Deere franchise in Hamburg, Iowa. Today the two locations along the river have approximately 70 employees engaged in selling and servicing John Deere equipment to local farmer customers.

The proposed changes in the management of the Missouri River will have 2 key effects to our business, employees, and communities. First, higher river levels in the Spring will hinder the ability for farmers to plant crops in a timely manner and potentially prevent planting of many acres at all. Reduced yields and acreages will create less profitable farming operations ultimately reducing the needs of local farmers for equipment and services provided by AgriVision Equipment and its employees. The second effect of a higher Spring rise of the Missouri River is the risk of flooding. The Hamburg and Pacific Junction locations were forced to move out of their facilities in 2011 at an astounding financial burden. Flood protection needs to also be a consideration in the operation of the Missouri River.

The ability of farmers in the Missouri River valley to produce crops at a profitable level are paramount to the economies of all of the communities along the Missouri River. AgriVision Equipment would ask that when considering how to manage the Missouri River that economic impacts to farmers and communities and even the possibility of loss of human lives along the river be taken into serious account.

Sincerely,
Jon Graves

I believe Alternative 2 because it best protects endangered species and their habitats. The Alternative 2 should also consider other species that are approaching endangerment because of MO River management as well as non-native species that are invading the MO River ecosystem like the Asian carp.

Option #1 or Option #3 would be least offensive to those who live and farm close to the Missouri River. Why should a bird or fish be more important than the lives of people?
You must take into consideration how you may increase the cost of planting, harvesting, and the cost of utilities (mid-American Energy) costs (SIRE - Southwest Iowa Renewable Energy).
It has occurred to many that you are trying to put farmers out of business completely. These are families!
2 Rises which would put crops at risk do not take into consideration natural weather conditions. Please don't forget the human element!
How does the Corps prove that these Rises actually help? You are polluting the River by dumping soil back into the river. This also raises the river.
These birds and fish exist in other areas.
Navigation should be considered.
Valentine's Day!?
This site was very difficult to find. I am not familiar with UNO - signage was bad.
Please consider the people who live and make a living along the river.

RE: Damage to recently repaired levees

To whom it may concern:

We, the Trustees, of the Pigeon Drainage District #2, Sub 1, Sub 2, and Sub 3 are writing this letter to serve as our written objection to the Army Corp of Engineer's plan to create an artificial rise of the Missouri River in Spring of the upcoming years. This is in a manner that is inconsistent with historical flooding of the Missouri River and in a manner, that will jeopardize the work the Drainage District has done since the unprecedented flooding of 2011.

Historically, when the Missouri River rose it would recede as quickly as it came up, however the Army Corp is proposing that the river raise at least nine (9) feet for more than thirty (30) days. In our opinion, as persons from farming families who have been in the area for multiple generations, this is not replicating historical flood data, rather simply allowing the Army Corp an opportunity to further their own agenda in repopulating birds.

The Drainage District has worked very hard, to the burden of the tax payers within the district, since 2011 in an effort to restore and repair the levee system that was damaged in 2011. Currently the data states that the levees would be able to withstand a rise to twenty-seven (27) feet. However, there is no question that extended flooding at that level would compromise the integrity of the recently repaired levees. Once again, forcing unnecessary burdens and risks on the people living and farming within the Drainage District.

Therefore, we as the Board of Trustees for the Pigeon Drainage District #2, Sub 1, Sub 2, and Sub 3 are sending this written objection to the Army Corp of Engineers prior to this disastrous decision making course being taken.

Very truly yours,

Ashley N. West
Frank Moran
Dale Rief
Roger Clark

My answer to the possibility to the Spring rise and fall rise, is we don't know if it is going to do any good for the fish and wildlife. The only thing that we know is if it's going to cost the tax payers up and down the river a lot of money. Because they can't get crops planted or harvested.

If your employee calls you up and told you that you can only receive 30% of your money.

I am an environmentalist, I like fish and wildlife too, but we need to have a happy medium, it can't be all one way.

Several years ago we had a high fall rise, and it probably cost me \$100,000+ lost revenue and machinery repairs. I have supported the Corp but this is getting completely out of hand. We could have another 2011. I do hope you will consider this!

Thank you.

Max Peeler

The West Pottawattamie County Farm Bureau appreciates the opportunity to comments on the Draft Missouri River Recovery Management Plan and Environmental Impact Statement.

The Missouri River serves as an important asset to farmers, landowners, businesses and communities along the river.

Altering the flow will have negative effects on drainage and infrastructure near and far from the river. This is clearly evident from the 2011 flood where the effects are still a problem from a fiscal and hardship issues. Several drainage and levy districts are concerned about the tax levy's that were added to property taxes on the repairs to levy's and drainage districts might happen again. Also, everyone is worried about structural integrity of levy's since the 2011 event. Many of the fish, birds, habitat and infrastructure that you were trying to save were devastated. We feel the management of the river for flood control and drainage should be upmost importance.

Farm Bureau policy opposes any plans by the U.S. Army Corps of Engineers or any federal or state agencies that would alter the flow levels of the Missouri or any river and would adversely affect domestic water supplies, drainage, irrigation and transportation, that would cause traffic bottlenecks on the Missouri or any navigable river and take private property without compensation. We also oppose the dumping or designed erosion of soil into waterways.

Farm Bureau will be reviewing the Draft Missouri River Recovery Management Plan and Environmental Impact Statement with respect to this policy. Farm Bureau will be coordinating this review and final comments with other agricultural organizations and state government.

Thanks again for the opportunity to provide these preliminary comments.

Sincerely,
Mike Schropp

The Missouri Corn Growers Association (MCGA) represents the interests of corn farmers from across the state of Missouri. Many of those growers live and work in the Missouri River bottoms. Over the years, we have consistently advocated for the prioritization of flood control and navigation when it comes to Missouri River management.

The Draft Environmental Impact Statement out for comment contains six alternatives. Unfortunately, all six alternatives contain some level on increased flood risk via a spring rise. This runs directly contrary to the Corps flood control mission. In addition, there continues to be zero science that supports a spring rise and its benefit to pallid sturgeon.

MCGA has never wavered in its opposition to the spring rise as a management tool. Though alternative three has less commitment to the rise, it still unfortunately leaves the door open. As mentioned before, science has failed to support a spring rise and therefore it should not be a component of any of the alternatives. We must not increase the risk of flooding during this critical time of year, planting season.

MCGA is encouraged the comment period has been extended for the draft DEIS, and looks forward to submitting more extensive comments on the proposals.

What are you doing to develop overall natural river, riparian habitat to help the pallid sturgeon? The IRC and spawning areas seem to require ongoing maintenance. What are you doing for ongoing natural habitat for adult pallid sturgeon?
Why are you not emphasizing acquiring more acres to restore the river?

Thank you.

I own a house at Big Lake Mo. We were flooded in 2010 and 2011 by the corp of engineers. The river levels in the spring were too high (major release of water from Gavins dam). We only received a few inches of rain just north of us and then we were flooded.
I would think after 2011 when the corps caused so much damage that I would not see what is happening in 2017.
Down stream does matter. Flooded land in Missouri does matter.

I favor Alternative 2 (even though flawed) and here's why:

1. Alternative 2 is best, but needs changes. It provides the best opportunities for recovery of the three species. It provides adaptive management over time. Alternative 2 includes recognition of the importance of connections to floodplains and includes the option of acquiring increased acres for habitat and mitigation. Alternative 2 is the best option to move toward a more natural river which is good for the three targeted species as well as other fish and wildlife species. The Corps incorrectly sets the cost of Alternative 2 as too high. The Corps has included too much mechanically created habitat in Alternative 2 which unnecessarily raises its cost. Also the Corps does not consider the environmental services that would be provided by additional habitat acres over the years. Those services include flood risk reduction and recreation.
2. The Corps' preferred alternative, Alternative 3, is the worst of the choices. It relies only on manual, artificially created habitat which would require indefinite work and maintenance. Alternative 3 would lock the Corps into a substandard, costly plan. The Corps wants to be a zookeeper along the river, instead of creating a more natural river.
3. The Corps should create a reasonable range of alternatives as required by law.
4. The DEIS document should be subject to independent scientific review.
5. We should protect endangered species by restoring a more natural river for all fish and wildlife.

Thank you.
Sarah

 Notes: Transcript from the public meeting in Bismarck, ND (Bismarck State College) on 2/8/2017

Correspondence Text

Good evening. Welcome to North Dakota. My name is Garland Erbele. I'm the North Dakota State Engineer and Chief Engineer at the State Water Commission.

Thank you for coming to Bismarck to take comments on the Missouri River Recovery Management Plan and Environmental Impact Statement. The State Water Commission in coordination with other state agencies is in the process of reviewing the 500,000

- - 5,000 pages of EIS and supporting documents. Therefore, we appreciate the extension to the comment period as it will greatly aid in our providing thorough comment and review to the Corps.

At this point, I must stress its importance the Corps working with the state through the implementation of adaptive management of Missouri River Recovery Program. We have serious concerns with respect to potential changes in the Master Manual. The EIS includes alternatives with several flow-of-management actions that would deviate from the current Master Manual. The Adaptive Management Plan adds another layer of uncertainty due to its lack of sideboards and vagueness in how the states would be involved in the decision-making process if the Master Manual were to change.

For these high-consequence decisions, there needs to be an avenue for direct consultation with experts from various state agencies who understand their authorities and responsibilities, know what questions to ask, and can recognize concerns. This is necessary to ensure that the federal government complies with state regulations and does not do something that significantly, adversely impacts the states and their right to manage natural resources within their borders.

In order to alleviate these concerns, these need - - there needs to be a guarantee in the Adaptive Management Plan that if any actions are proposed to occur outside the conditions of the Master Manual, the Corps will consult with states before making any substantive modifications, apart from MRRIC, Fish and Wildlife Coordination Act, and the Annual Operating Plan process. State representatives on MRRIC are striving to reach consensus on language to be included in the Adaptive Management Plan that articulates this stipulation.

Also of significant importance is a continuation of annual consultation with the North Dakota Emergent - - Interagency Emergent Habitat Sandbar Team. This consultation has occurred for several years and allows discussion of recovery program management actions planned in North Dakota for the coming year. This annual meeting has greatly improved communication between the Corps and North Dakota. It is expected this annual consultation will continue during future implementations of adaptive management.

We look forward to working with the Corps to improve the Missouri River Recovery Management Plan and Environmental Impact Statement and appreciate your consideration of our comments. Thank you.

Correspondence Text

Okay. All right. I'm Shirley Marvin. I'm an enrolled member of the Standing Rock Sioux Tribe. And I'm also the chairperson for our commission on elderly people, and that amounts to about 400 people on the reservation.

I came up here intending to listen with a good heart to everything that was said. And right off the bat, this gentleman upset me because the Corps has no right to give away my water or my land. You are only here to manage that for us. You do not own it and you cannot give it away. If you don't believe me, this document says so; it's the Treaty of Fort Laramie.

And this document was signed by over 15 tribes. Then why is only Standing Rock here? The other tribes have something to say too, and they will be talking. I could let - - read off all the identifying names for the tribes that signed this treaty. And it's still in place. We live by this treaty. It's called a treaty of peace, because when we signed this, we intended to live in peace.

Except that made us wonder what happened here recently. People were shooting at us. You know what happened. You seen it on TV every night. So that really puts us in a dangerous position because within our treaty, it says, "From this day forward" - - and that is April 29, 1868, "From this day forward, all war between the parties to this agreement shall forever cease. The Government of the United States desires peace, and its honor is hereby pledged to keep it. The Indians desire peace, and they now pledge their honor to maintain it."

If bad men among the whites or among their people - - other people subject to the authority of the United States shall commit any wrongdoing upon the person or property of the Indians - - and that means our water and our land - - the United States shall, upon proof, made to the agent forwarded to the Commissioner of the United - - of the Indian Affairs at Washington City, proceed at once to cause the offender to be arrested and punished according to the laws of the United States, and also reimburse the injured person for the land - - for the land that was destroyed.

If bad men among the Indians shall commit a wrong or depredation upon the person or persons on any one white, black, or Indian, subject to the authority of the United States and at peace herewith, the Indians herein named solemnly agree that they will, upon proof, made to their agency and agent and notice by him deliver up the wrongdoing to the United States.

So here's a section of this treaty that provides us the peace that we were going to keep. It makes it pretty damn hard when you're shot at with rubber bullets that can kill a person. We went through it all. And now people are jumping in saying, Well, if it's in our border - - we signed this in peace. And if we're going to maintain our peace, then you have to maintain it too.

And just because we're in trouble with it right now doesn't mean that you're going to jump in and take it away from us because I want to remind you, there's between 17 and 18 tribes that signed this. And they all have a right to come in here and be heard. You said you have attorneys here. Do you believe that, that the other tribes should be here; or was this just for us? You know very well it belongs to all the tribes, and they will be here. And you're going to have to answer to them, not just me.

And you - - you talked about the pallid sturgeon and these other two birds for the last 20 years. I worked for Lower Brule 20 years ago. We talked with the Corps of Engineers about these birds and these fish. 20 years ago, we were worried about them; and you're still working on it, for heaven's sakes. It must have been more fish or more birds than you thought.

So I'm - - I'm angry because I remember what my parents went through, my grandparents. Some of you don't even know where you came from. You're still looking for your grandparents. You still want to know who they are. Every day on TV I see, Oh, I'm looking for my grandmother, and I just found out she comes from eastern Europe. And you people don't even know where you come from. And, yet, now you want to go out and take the rest of our land and our water. That's not going to happen.

And remember, we voted up here too. We voted up here in North Dakota. And there's a lot more tribes here than me, than Standing Rock. So you had better do some thinking because I'm not going to keep quiet, and I'm going to take more than three minutes because everybody else had more than three minutes. So I'm taking my three minutes the way I want to.

So you can tell yourselves that. Is she just an old woman? She doesn't know. Might be an old woman, but I know where I come from. I know who my people were and are.

COMMANDER HENDERSON: Ms. Marvin, I'm granting you the privilege and respect for using the extended time. I would ask that you reciprocate that respect by focusing on the topic here and being respectful for everybody in the audience.

MS. MARVIN: I have a right to - -

COMMANDER HENDERSON: You do.

MS. MARVIN: But when someone comes up here and talks about taking away my land and my water, he could have the respect to come to our tribes if he wanted to say something about it. So that works both ways.

Thank you.

Correspondence Text

MR. ENGEMANN: Good evening. My name is Dan Engemann, D-A-N, E-N-G-E-M-A-N-N. I serve as executive director of the Coalition to Protect the Missouri River. The Coalition is made up of a variety of interests and supports the congressionally authorized purposes of flood control, navigation, water quality and water supply. We also support endangered species recovery.

We appreciate the opportunity to comment on the Draft Environmental Impact Statement of which several of our members and I have been heavily involved in as part of the MRRIC process.

Of the six alternatives presented to us for review and comment, the Coalition supports a mechanical sandbar habitat construction contained in each of the alternatives. However, we cannot support various flow modifications common to alternatives 2, 4, 5 and 6.

Low summer flow provisions in alternative 2 will cause great harm to the navigation industry by creating a split season on the Missouri River and adversely affecting navigation flows on the middle Mississippi River. It has the potential to negatively impact water and sewer treatment plants, as well as power plants, creating problems with intakes and increasing the risk of failure to comply with conditions of discharge permits.

Alternatives 4 and 5 create unacceptable amounts of flooding risk in the spring and fall, increasing downstream flood control constraints and doubling releases from Gavins Point for 35 days.

Regarding alternative 6, our members do not support the implementation of a full bi-modal release because of the risks to flood control and impacts to interior drainage.

We believe the Corps' preferred alternative 3 strikes a better balance between the human interests and species recovery. However, our members are concerned about the potential for flooding and impacts to interior drainage as part of a one-time flow test included in this alternative.

The Coalition supports eliminating the current bi-modal spring rise from the preferred alternative because no science has been developed to prove its value.

We applaud the Corps for their commitment to study the linkage between tributary flows and pallid sturgeon recovery. However, we question how the Corps can keep such an option "on the shelf" for nine to ten years in the future as part of this alternative, knowing that river conditions can change during this time, making human consideration effects difficult to monitor. We're concerned that this one-time flow test could be part of a permanent flow regime.

Flow rises in other alternatives raise questions about implementations, as those actions require amending the Master Manual. We oppose such revision because the time involved, the risk to the species and the potential for litigation during which time the species could decline even further. Should the Corps choose something other than alternative 3, the process for creating flow changes needs to be clear to stakeholders and be aligned with the Master Manual.

For the same reasons, any adaptive management actions could cause concern. Whenever new actions are proposed or existing actions are modified, including those outside the Record of Decision, they must be subject to thorough review, including public comment and EIS impact assessments and be in compliance with the Master Manual.

The Coalition to Protect the Missouri River will be offering comprehensive comments in advance of the extended comment period deadline.

Thank you for your traveling to the basin to hear stakeholders' thoughts and concerns on this important matter.

MR. HART: Okay. My name is Vern Hart, V-E-R-N, H-A-R-T. My family and I farm in Buchanan County, and I am a member of the Missouri Farm Bureau State Board of Directors.

Missouri Farm Bureau is the state's largest farm organization. Many of our members' livelihoods are tied to the Missouri River and, thus, we've been involved in the management issues for more than two decades.

Many Missourians continue to believe that common sense must be the foundation of our government's management decisions. We're hopeful the Trump administration will recognize the shortcomings of the current federal regulations and hit the reset button.

Missouri Congresswoman Vicky Hartzler recently gave the President her "Undo" list. This includes many offensive rules, regulations and mandates that have affected her constituents. What a great starting point.

Almost a quarter of our state counties border the Missouri River. A new study shows in those 25 counties, agriculture, forestry and related industries had an economic impact of \$34.6 billion in 2016. Agriculture's contribution includes \$21.2 billion in inputs, over 135,000 jobs and \$2.8 billion in federal, state and local taxes.

Our organization's resolve relative to the Missouri River issues has only been strengthened over time. We believe flood control and commercial navigation are priorities when considering authorized uses. Much as our state's drinking water comes from the Missouri River, and we support flows for power generation and continued close coordination with levee districts.

We will not support proposals that weaken flood control, initiate pulses or reduce flows in the summer. We do not support construction as chutes and oppose actions that could damage private property, weaken levees or lead to large quantities of soil being deposited into the river.

Given past experience, we're skeptical of adaptive management and what we consider to be very expensive experiments.

For the reasons stated, several of the alternatives under consideration are nonstarters. Given the prescribed flow modifications, we do not support alternatives 2, 4, 5 and 6. Alternative 1 is a concern that it continues to allow for a bi-modal spring rise and the construction of shallow water habitat. While alternative 3 does not call for shallow water habitat, it does require Interception Rearing Complexes, which of those who know the Missouri River simply consider more hocus-pocus. Furthermore, alternative 3 does not rule out flow modifications.

There must also be consideration of cost. Every man, woman and child in the US currently owes over \$65,000 for their share of the \$19.9 trillion public debt. We have to be aware of expenses associated with each of the proposed alternatives.

We're not asking to give up any bird or fish, but common sense has to be a part of the equation. The Endangered Species Act must be updated. Consideration of human impacts must come first and no one should be held hostage by the views of personnel within the US Fish & Wildlife Service, Environmental Protection Agency or any other arm of the government. Thank you.

Correspondence Text

MS. ROUSE: Karen Rouse, K-A-R-E-N, R-O-U-S-E. I'm from Jefferson City, Missouri.

I am the Surface Water Chief for the Water Resources Center of the Missouri Department of Natural Resources. The Missouri DNR represents the State of Missouri on interstate water issues and I am Missouri's representative to the Missouri River Recovery Implementation Committee. Thank you for this opportunity to provide comments on the Missouri River Recovery Program Draft EIS.

Our message has been consistent. First, flood control and navigation are the primary purposes of the Missouri River System, and as such, the Corps must implement Recovery Program actions without preemption of fully accomplishing those critical and existing lawful uses of the system.

Secondly, several of the proposed alternatives would modify the flood control constraints of the system, which would require a change to the Master Manual. For example, under alternatives 4 and 5, the flood control constraints are increased by at least 30,000 cfs. This action would be contrary to flood control.

Third, if the Corps would consider changing the Master Manual, that would require a separate public process and cannot be embedded in any other process. Should the Corps pursue a deviation to the Master Manual for a one-time flow event, it is imperative that the Corps consult with the governors of the states before implementing this high consequence action.

Furthermore, the proposed flow events use water from the carryover storage pool, which is the pool we rely on during times of water shortage. The navigation flow support releases from the system benefit many uses on the lower river such as water supply, energy production, recreation and fish and wildlife. In Missouri, over 3 million people rely on the Missouri River or its alluvium as its water source. Reductions in navigation flow support have cascading impacts not only to uses on the Missouri River,

but also on the Mississippi River, which is 40% of the flow to the middle Mississippi during normal conditions, and peaked at more than 70% during the 2012 drought.

The department supports the Corps' intention to use natural flow events to improve our scientific understanding. In Missouri, the river is already highly variable where it's known to rise 15 feet within a 12-hour period from localized rain events. The 2011 Independent Science Advisory Panel noted that the natural rise had "...not been adequately or systematically assessed." Because of this, we believe there is no additional - - there is no need for additional water to be released from Gavins Point.

The State of Missouri supports the preferred alternative identified by the Corps in the Draft EIS with the exception of the potential one-time flow event. This one-time flow event was neither modeled nor were the impacts assessed in the Draft EIS 'because of uncertainty of the hydrologic conditions present'.

Given our high frequency of flood events in our state, we have always been very concerned about any proposed environmental flows from Gavins Point Dam that exceeded flood control constraints. Let me be clear: The State of Missouri cannot support any alternative that includes environmental flows that exceed current flood control constraints.

The State of Missouri would also like to reiterate to the Corps that decision-making within the Adaptive Management Plan needs to be open and transparent. All of the states represented in MRRIC agree that consultation and coordination with the states' governors' offices on matters of high consequence is imperative.

Thank you again for this opportunity to provide public comments. The State of Missouri looks forward to further dialogue on this issue as the EIS process continues.

Correspondence Text

MR. POER: Good evening. My name is Tom Poer. I'm the - - currently serving as the President of the MOARC, the Missouri and Associated Rivers Coalition.

MOARC was established in 1952 in response to severe flooding that ravaged the Midwest in 1951. Since then, MOARC has advocated for flood control and water conservation in the Missouri River basin. MOARC works to educate, present and learn about current ideas on water resources management in partnership with the Corps of Engineers, and promotes responsible management of the Missouri River supporting all eight of its authorized purposes based on sound science.

The Draft EIS is a complex, technical and extremely long document with the potential to have adverse effects on many of our members' operations depending on the alternative chosen and the subsequent Record of Decision.

A thorough review will take a great deal time and effort. This is especially true for MOARC due to our extensive degree of member operations necessitating that we fully review all areas of the Plan and Draft EIS.

At this juncture, our review of - in our review, our executive board feels alternative 3 will have the least effects on the authorized purposes and our members, despite our concerns with a possible spawning cue flow regime in the out-years seven through nine. Full analysis of all alternatives by our board and committee members will be submitted later in the comment period.

We thank you for this opportunity to make these brief remarks.

Correspondence Text

MS. GIESSEL: All right. My name is Elaine Giessel. That's spelled G-I-E-S-S-E-L. I live in Overland Park, Kansas, and I'm representing the Sierra Club tonight, the Kansas Chapter, and particularly the Kanza Group of the Sierra Club.

I would like to thank the Corps first for extending the comment period so the public would have adequate time to review these lengthy documents. The Sierra Club will be submitting formal comments on the Missouri River DEIS at a later date.

At this time I would like to enter into the record several comments/questions on behalf of the Sierra Club.

The Sierra Club focuses on maintaining and working towards whole and healthy natural systems. If artificial improvements like dams, the armoring of banks and levees are the main cause of loss of habitat, then the preferred alternative should address the root cause of the problem, which may mean removing some of this structural implementation.

Alternative 2 appears to provide the best opportunities for recovery of the three federally listed species. It includes recognition of the importance of connections to the flood plains, the option of acquiring increased acreage for habitat and mitigation, and provides for adaptive management over time.

One of the questions we have is how the Bank Stabilization & Navigation Fish & Wildlife Mitigation Project will be impacted by this, whether it will be folded in, superseded, or continue its work. The land that is being put into habitat mitigation under that project also creates recreational opportunities for the public.

The jeopardy to the three federally listed species is clearly the driver for this Draft EIS, but given the amount of time and money invested in this recovery and management plan, the Sierra Club is

concerned that the impacts of the various alternatives on other species have not been considered. It is not an ecosystem-based management plan and does not include evaluation of state-listed species here in Kansas and other states, or species that are currently considered candidates for state and/or federal listing. Thank you.

Correspondence Text

MR. KLENDER: Good evening. My name Mike Klender, M-I-K-E, K-L-E-N-D-E-R.

I'd like to thank the Corps for allowing me to present comments to the Draft EIS rule. As President of the Missouri River Public Water Supplies Association, I represent 18 water supplies from Sioux City down to St. Louis on the Missouri River, and one on the Mississippi River. We will be formally submitting a written response before the April 24th deadline.

The water supplies of this association want to remind the Corps their obligation to meet all eight authorized purposes, which water supplies are one of the eight authorized purposes.

We had considered - - we have concerns about the information provided in the Water Supply technical memo. The information presented in this memo has a lot of the members in the association asking more questions as to where the Corps obtained their data. The information on the size of pumps and costs necessary to draw the water from the river seems to be underestimated. Trying to locate large pumps larger than 7,000 gallons a minute to rent would be a difficult task, especially if half the members of this association must find these large pumps. Some of the information presented seems to be grossly underestimating the impact if the water supplies are not able to have access to the river. The size of the pumps necessary to draw water and costs associated with finding large enough pumps to operate. The water supplies in this association service over 4 million customers, and billions in industrial commerce and services which depend on the water from the Missouri River.

We do not feel this technical memo allows for the seven recommended actions made by the MRRIC in 2012 to evaluate the effects analysis.

Consideration needs to be also included the degradation that is ongoing on portions of the Missouri River. Of the alternatives presented in this EIS, alternative 3 is the least impact to the eight authorized purposes. Again, thank you for allowing me to speak.

Correspondence Text

MR. HORGAN: Good evening. My name is Tom Horgan, H-O-R-G-A-N. I'm the Senior Manager of the Mid-continent Office for the American Waterways Operators, or AWO.

The American Waterways Operators is the national advocate for the US, tugboat, towboat and barge industry, which serves as the nations - which serves the nation as the safest, most environmentally friendly, and most economical mode of transportation.

On behalf of our members, I appreciate the opportunity to comment on the Draft Environmental Impact Statement for the Missouri River Recovery Management Plan. On behalf of AWO members, AWO staff has served as a member of MRRIC committee.

First of all, AWO supports the recovery of the endangered pallid sturgeon and the threatened least tern and piping plover, and believe that these species can be recovered without changes to the Master Manual or any other major flow modifications to the mainstem reservoir system.

Of the six alternatives presented to us for review and comment, the AWO supports mechanical sandbar habitat construction contained in each of the alternatives, including the preferred alternative number 3. However, AWO strongly opposes the various flow modifications common to alternatives 2, 4, 5 and 6. Low summer flow provisions in alternative 2 will cause irreparable harm to the navigation industry by creating a split navigation season on the Missouri River, virtually killing navigation on the river.

In addition to this, low summer flows in alternative 2 will have severe negative impacts on navigation on the Mississippi River from St. Louis all the way downstream to Cairo, Illinois. During severe drought on the - - during severe drought years, over 80% of the water flowing past the St. Louis Arch comes from the Mississippi - - from the Missouri River. These flows are necessary to keep this commercial

superhighway open.

Alternatives 4 and 5 create unacceptable amounts of flooding risk in the spring and fall, increasing downstream flood control constraints and doubling releases from Gavins Point for 35 days.

Regarding alternative 6, AWO opposes the implementation of a full bi-modal spring release because of the risk to flood control and its negative impacts to navigation and the lack of science that confirms that these flows would facilitate the recovery of species.

We believe that the Corps' preferred alternative strikes - - alternative 3 strikes the best balance between species recovery and human considerations. This alternative meets the species targets for birds while causing the least amount of impacts to stakeholders.

Furthermore, we commend the Corps for their commitment to study the correlation between tributary flows and pallid sturgeon habitat. However, AWO members believe that any flow test is scientifically unjustified.

AWO supports eliminating the one-time flow test, or bi-modal spring pulse, from the preferred alternative virtually because there is no science that has been developed to prove its value.

AWO is very concerned about the implementation of any preferred alternative under an Adaptive Management Plan. Our members are particularly concerned with the section of the Adaptive Management Plan dealing with management actions outside the Record of Decision. Whenever new actions are proposed or existing actions modified, those changes must be subject to thorough review, including public comment and environmental impact statements under NEPA.

Thank you for your time tonight, and AWO will be submitting comments - - written comments on behalf of the record, and we thank you for extending the period of comment deadline.

Correspondence Text

MR. SHORR: Thank you, Colonel. My name is David Shorr, S-H-O-R-R. I'm from Jefferson City, Missouri. I'm an attorney with the law firm of Lathrop & Gage, and I represent the Commercial Sand Dredging Interests on the Missouri River. I'm also a member of the Missouri River Recovery Implementation Committee where I serve as a stakeholder representing waterway industries.

Tonight I would like to make a few comments regarding issues that are presented in the Draft EIS relating to the management plan. These represent interim comments and we will follow with formal comments during the comment period.

We support adaptive management as a method to expedite knowledge, generate scientific information and test hypotheses. We believe that adaptive management provides for a more nimble position for the Corps in making decisions for our protection of endangered species. However, we find no legal premise for the adaptive management scenario to exceed the guidelines and provisions of the Master Manual on its own accord. As such, we believe that this process does not allow or endorse changes to the manual without appropriate manual review, analysis, procedure and public hearings.

Modifications in flow as presented in alternatives 2, 4, 5 and 6 undermine the primary purposes of navigation and flood control and are, therefore, problematic.

Adaptive management's governance framework isolates stakeholders and relegates them to a lower status in the pyramid. The adaptive management process compromises the authority of the governors in the basin to a lower priority in the decision-making. These elected representatives of the various states should have some of the highest position with regard to this process.

While we have no objections - - while we have objections to the use of certain sediment-related models on the micro level, we recognize that the reduction in sediment as a result of a the five mainstem dams and the equilibrium that now exists with regards to the Bank Stabilization and

Navigation Project requires a true sediment analysis to be created. At the macro level, this analysis should determine the lack of material in the system, the failure to recognize sediment as an important component for the preservation of the pallid sturgeon continues to be a fundamental error in the alternatives.

Changes in flow without enhancing the sediment load have no value and are a waste of precious water in the system. It almost appears that the DEIS and other evaluations purposefully neglect the issue of material in the system and the dramatic reduction of material movement throughout.

We believe that all the hypotheses are incomplete with regard to the pallid sturgeon unless additional sediment load is put back into the system.

We appreciate that this DEIS acknowledges the existence of the middle Mississippi and that it is, in fact, integrated with the Missouri River. However, the impacts relating to middle Miss are direct and not cumulative. For all practical purposes, the relationship with the middle Miss and Missouri River, pallid is limited. Flow and lack thereof affect the performance of the middle Miss and have significant social and economic consequences to the users of the Missouri River.

The failure to directly examine impacts alternatives to the middle Miss in a direct fashion and to ignore science indicates the Pallid's potential gain would required greater examination.

Interception Rearing Complexes by both - - are by - - by both Fish & Wildlife in the course of experiments, we do not object to the advancement of hypotheticals provided there's graduated and there's adequate evaluation of channel integrity.

Of the alternatives presented, we support the preferred alternative. We wish to acknowledge the hard work that's been put in, the effort. While we may not agree on every element, we wish to acknowledge the actions of the Corps, of Fish & Wildlife, members of MRRIC on this significant undertaking. There is no way to deny the hard work of many individuals to create the opportunity for this review and dialogue. Thank you.

Correspondence Text

MR. WATERS: Good evening. My name is Tom Waters, W-A-T-E-R-S. I serve as Chairman of the Missouri Levee and Drainage District Association. Our association consists of levee districts, drainage districts, businesses and individuals affected by the Missouri River and its tributaries.

Colonel, I'm disappointed you had to be the person selected to moderate tonight's hearing. Major General Spellmon's decision not to attend these public hearings only highlights the lack of importance he and the Corps places on these hearings, and more importantly, the concerns of those attending the hearings. By not attending, there's no way for the General to understand the level of passion in the voices and comments presented by the public. The decision-maker in an effort this big that impacts so many lives should have to look these people in the eye and listen to their concerns.

I'm here tonight to remind the Corps of their flood control mission. The Draft Environmental Impact Statement contains six alternatives. I find it appalling each alternative increases the risk of flooding. It is clear the Corps and Fish & Wildlife Services turned their back on flood control. All the alternatives - - all the alternatives propose a spring or fall rise.

Alternatives 4 and 5 represent the most audacious lack of concern for the citizens impacted by Missouri River management. The 60,000 cfs release found in these two alternatives is an outrageous demonstration of the Corps' disregard for and the failure to pursue its flood control mission.

Alternative 1, 2 and 6 contain lesser rises, but still threaten those downstream with increased flows.

Alterative 3 contains a stipulation containing its own possible spring rise after a few years of monitoring. This caveat is an open door for those managing the river to dump more water on those downstream.

At what point will the United States Army Corps of Engineers understand it is wrong to intentionally

flood those they have been directed to protect?

Congress has directed the Corps to provide flood control for the citizens of our nation. Now it is apparent the Northwestern Division has no intention to follow the direction of Congress, and many of the people in this room will suffer for the Division's arrogance and lack of respect for Congress and those impacted by the Corps' poor decisions.

Our association as always and will continue to oppose using increased flows as management options. This type of management by the Corps - - by the Corps' own admission in federal court is designed to cause intentional flooding.

We believe the threatened and endangered species can be recovered while the Corps continues to provide flood control. The Corps and the US Fish & Wildlife Service should and can find ways to protect the species without harming our communities.

Finally, the 8th Circuit Court of Appeals in their 2005 decision clearly stated, quote, if due to extreme conditions the Corps is faced in the future with the unhappy choice of abandoning flood control and navigation on the one hand, and recreation, Fish & Wildlife on the other, that priorities established in the Flood Control Act would forbid the abandonment of flood control or navigation.

In the same document, the Court reiterated its earlier opinion that the Flood Control Act has been interpreted to hold flood control and navigation dominate and recreation and Fish & Wildlife secondary. The Northwestern Division would do well to follow the advice of the federal court.

The Corps of Engineers has a moral obligation, a duty and a mission outlined by Congress to provide flood control for the citizens of our country. The Northwestern Division should not turn its back on Congress and should find a way to protect these species while following through with their flood control mission. This is a charge of Congress and it's the desire of the people. However, this is not what the Draft Environmental Impact Statement sets out to do. There must be a better way, and the Division should continue to work to find it without implementing the alternatives in the Draft Environment Impact Statement. Thank you.

Correspondence Text

MR. FRAKES: My name is Lanny Frakes, L-A-N-N-Y, F-R-A-K-E-S. I'm Vice Chairman of the Missouri Levee and Drainage District Association. I'm involved with two local levee districts, one federal, one non-federal, in Buchanan and Platt counties, and I'm a farmer.

I didn't have a prepared statement tonight. I just planned to just make a written comment previous to April 24th.

In referring to the executive summary booklet that you passed out here tonight, I've had very little time to read that. Land ownership within the Missouri River floodplain includes federal, state and local government lands, tribal lands and private lands. Various land uses are practiced within the Missouri River floodplain, including developed lands, agriculture lands, open water and other types of use. Developed land refers to communities, towns and cities, including commercial, industrial and residential uses, as well as the lands developed to support transportation, highways, roads, bridges, railroads and other infrastructure. Agriculture is the dominant land use in the floodplain between Gavins Point and the mouth, accounting for between 63% to 72% of the floodplain land.

And then another paragraph, a main objective for the mainstem reservoir system is to regulate the reservoirs to reduce the risk the Missouri River flows from contributing to flood damage and the reaches downstream from dams. Regulation of individual reservoirs is coordinated to reduce flood risk from a particular reservoir.

And on the next page, levees also play a role in flood risk management along the Missouri River. Federal agriculture levee construction in accordance with the 1941 and 1944 Flood Control Acts began in 1947. Most existing federal levees are in the reach located between Omaha and Kansas City. The levees help to manage flood risks to these localities during the most severe flood events of record. Between Sioux City and the mouth of the Missouri River, local interests have built many miles of levees consisting of about 500 nonfederal units through this reach of the river. Most of these levees are inadequate to withstand major floods, but generally protect against floods smaller than a 5%

annual chance of exceedance event for 20 years.

Water surface elevations within the landward side of the federal levees are affected by the ability to drain interior runoff into the Missouri River. And I'll add this as existing in nonfederal units. High water can result in poor drainage, higher groundwater, blocked access and associated damage and inconvenience. Hundreds of individual gravity drainage structures, culverts with flapgates and pumping plants exist along levees near the Missouri River. The Kansas City and Omaha US Army Corps of Engineer districts have surveyed data on approximately 1,400 individual interior drainage structures. And the alternative evaluated include management action with potential to affect river flows.

On 2, 4, 5 and 6, these will affect these levees. This will affect what I've talked about, what I mentioned from your executive summary, and it will affect them in a negative way. Once these releases or pulses come from Gavins Point, they can't be taken back.

You're putting the livelihoods of many people, infrastructure, and what I mentioned in this executive summary that you printed, you put that in a negative perspective and put us in jeopardy.

I thank you for the time to be able to make those remarks.

Correspondence Text

MR. ARMSTRONG: Thank you, Colonel. I'm Mike Armstrong, A-R-M-S-T-R-O-N-G. I'm General Manager of WaterOne. We are a public water utility located in Lenexa, Kansas. We provide drinking water for over 425,000 residents in Johnson County, Kansas. We operate surface water intakes on the Missouri and Kansas Rivers. I'm also a member of MRRIC, and since 2008 I have invested literally hundreds of hours working on this recovery process.

First of all, I want to remind the Corps that you're obligated to support the eight authorized purposes. Of those eight authorized purposes, we believe water supply is the most important to our communities. The Corps must do everything in your power to protect water supplies in the communities - - in the Missouri River basin. People should come first.

We support the preferred alternative number 3. It's not perfect, but it is the best of the six identified. One of the best things about alternative 3 is that it would abandon the 2000 and 2003 biological opinions which are - lack scientific basis and are both deeply flawed.

One area of the DEIS that we do have significant concern about is the method the Corps has used to model the impacts of the alternatives on water supply. The economists have used very theoretical and unrealistic assumptions. They have not considered real-world requirements, which are much higher than the minimums mentioned in the Master Manual, due to riverbed degradation, especially in the Kansas City, Leavenworth and St. Joe areas. This flaw was admitted several times in the DEIS, including 3-504 of the DEIS. I'll quote here that "...No Action Alternative does not reflect actual past or future conditions..." The economists use worst case scenarios of the Period of Record and then use hypothetical Master Manual minimum flows to create a baseline. This does not reflect reality. Because of riverbed degradation, the minimum flows mentioned in the Master Manual could not and would not support the water supply intakes in this stretch of the river.

As a result, the Corps has assumed that 33 of the 55 water intakes would experience 57 days below

operating thresholds, and 21 intakes would experience 14 days below shutdown elevations. These assumptions are totally unacceptable. The Corps should evaluate this approach and model realistic flow requirements to keep water supply intakes in operation at all times.

Finally, alternative 2 contemplates a low summer flow. There was absolutely no effort made to evaluate the impacts and cost associated with those low summer flows on water supply intakes. Although this is not the preferred alternative, it is important to document those impacts for the record. Thank you, sir.

MR. TOTZKE: Thank you, Colonel.
 My name is Greg Totzke, T-O-T-Z-K-E. I am the Water Quality Laboratory Manager for WaterOne.

As previously mentioned, we are a water utility that serves 430,000 residents, expanding 18 cities in the Kansas City Metropolitan area. The Missouri River flows and water quality are critical to meeting our customer needs for water. We appreciate the opportunity to comment on the DEIS and its technical reports.

Some of the key concerns we have are the Human Consideration Technical Report on the water supply is inconsistent in assessing risk, presuming the worst case for flows, but often the best case for water utility ability to respond. Not all low water conditions could be solved using submersible pumps. This is not a reasonable assumption. The idea that pumps could be rented by all utilities in a low water situation is unreasonable. Low water affects too many utilities at one time for all utilities to be able to rent pumps.

For larger utilities such as WaterOne, it is unlikely that large enough pumps could be rented to meet the supply needs available - could be - - to meet the supply needs will be available to us.

The assumption of the report is unrealistic and should be modified. The report failed to consider that at low water some utilities may have to lay miles of pipe just to reach the water supply. When the reservoirs get low, whole arms of the lake have dried up in the past. The river channel could also migrate away from the intake, and these costs should be considered in the report.

WaterOne spent \$2.4 million on permanent low water pumps for less than half of its intake capacity in 2003. The capital costs would be much greater than this today and the economic analysis should assume that those types of costs will have to be considered instead of renting pumps. The costs are severely understated. It is very likely that situations would occur that will leave some communities without water supply for days.

The report makes no estimated cost to those communities when they have no water supply. The cost impact to Cleveland in 2003 when a regional power outage left 1.5 million people in the city without water for two days was in the hundreds of millions of dollars when you consider the factories and businesses that were shut down. An outage would mean a loss in fire protection, the inability to cook, bathe or even flush toilets. A shutdown of critical facilities like hospitals and an increase in the risk of disease outbreaks without a water supply, a water supply outage becomes a state and federal disaster.

Thank you for your time.

Correspondence Text

MR. STEVENS: Thank you, Colonel.
 Charles Stevens, C-H-A-R-L-E-S, S-T-E-V-E-N-S.
 I'm speaking as a water utility officer. I'm speaking on behalf of Terry Leeds, our director.

Kansas City Water Services Department is responsible for providing water supply and waste water management not only for the citizens of Kansas City, but also to some 33 surrounding cities and utility districts. The department is also responsible for flood risk management in Kansas City through its management of pump stations and levees along the Missouri River.

The DEIS is a complex, technical and extremely long document with the potential to have adverse affects on many of our operations depending on the alternative chosen and the subsequent Record of Decision. A thorough review will take a great deal of time and effort. This is especially true for Kansas City due to our extensive operations involving the Missouri River necessitating that departmental staff fully review the impacts of all the alternatives.

At this juncture in our review, the department sees alterative 3 as the alternate that will have the least effects our operations and the authorized purposes, despite our concern with the possible spawning cue flow regime in out-years nine-plus. Full analysis of all alternatives by departmental staff will be submitted later in the comment period. We appreciate the opportunity to make these brief remarks.

Correspondence Text

MS. WIRTH: Good evening. I am Michelle Wirth, M-I-C-H-E-L-L-E, W-I-R-T-H, and I'm the Assistant Director of Production for WaterOne.

WaterOne, again, is a public water supply utility providing drinking water to over 425,000 residents of Johnson County, Kansas, including 18 cities. We have water supply intake on the Missouri, along with the collector well on the Missouri River, and we have an intake on the Kansas River.

As the largest water supply utility in Kansas, WaterOne has a responsibility to be a leader among its peers. We monitor and participate in advisory committees and interest groups involved with river policy, advocacy, preservation and water management, including participating in MRRIC.

I would like to reference the Human Considerations Technical Report- Water Supply, Section 3.1, Paragraph 2, which uses the Period of Record along with the minimum flow per the Master Manual as the flow condition. This worst case model scenario also does not include how often the scenario occurs. For example, does it include - - does it occur once every year or once every 25 years? The frequency of those occurrences and the associated costs should be included in the report.

Operational low flows in alternative 2 will negatively impact water quality parameters, which will require additional treatment techniques to be utilized by water suppliers to meet regulatory requirements. The costs for increased treatment and potential health risks were not addressed in the Human Considerations Technical Report- Water supply, and should be included in the report.

I, again, want to remind the Corps of the eight authorized purposes and that water supply is the most important to our communities. The Corps must protect water supply to ensure public health and safety.

The proposed strategies included in the Draft EIS included hypothesis with little to no scientific data to ensure with confidence that the strategies will make the direct impact on the species. We would not

support any development of hybrid alternatives.

WaterOne does continue to support alternative 3, which shows the least impact to water supply.

WaterOne will provide more detailed written comments and, again, appreciates the Corps that they have extended the comment period. Thank you for your time.

Attn: CENWO-pm-ac Management Plan Comments

I am writing to say that I favor Alternative 2 as the best option of the DEIS plan to manage the Missouri River.

Alternative 2 provides the best opportunities for recovery of the three endangered species. It also provides adaptive management over time.

I favor restoring a more natural river for all fish and wildlife, restoring the entire ecosystem. Alternative 3 is the worst of the choices because it relies only on manual, artificially created habitat which would require indefinite work and maintenance.

Thank you.
Francine Glass

Correspondence Text

JAMES BECIC: My name is Jim Becic.

I live at 5011 Parker Street in Omaha. I'm a biologist with a lifelong Missouri River interest. I've worked with the Corps and the Fish and Wildlife Service for over 35 years on projects for the river - - on the river.

I'm employed by the Papio-Missouri River Natural Resources District, and I am on the MRRIC committee, kind of redundant, but I'm not speaking for either of them.

My comments: I'd like to first compliment the Corps on their massive document/material, 6,000 pages, and also for extending the comment period for 30 days.

That being said, it's understood, at least by myself and a number of others, that "avoiding jeopardy" is the minimal that can be done for the three species that are fairly grossly shortsighted as far as the - - what we're trying to accomplish. I would prefer an ecosystem approach for restoration and strongly urge that.

I would like to link the bank stabilization navigation project (BSNP) mitigation requirements to this DEIS, as they would subsequently benefit all species, as opposed to just the three that are currently being considered as threatened or endangered.

It is viewed that the preferred alternative is wholly inadequate, that is Alternative No. 3 offered by the Corps. The most significant deficiency, in my opinion, is that there's an absence of acquiring additional floodplain acres and construction of shallow water habitat, as was pledged in the BSNP 2003 amended biological opinion.

It's understood that the Fish and Wildlife Service coordination act BiOp acquisition acreage requirements for the lower basin is currently deficient by approximately 100,000 acres. I'm going to get real close to my time.

It's feared and bears to be restated that while the authority for the amended BiOp remains, that there will likely be no priority for those once this DEIS is finalized. It's owed to the system.

Potential compromise would be to include Alternative No. 2 with the Alternative No. 3, if that's the preferred alternative. In saying that, if the science dictates a more aggressive approach, then this land habitat/acquisition could be accelerated and an adaptive management plan would be initiated.

Let's see. I have 30 seconds.

Very specifically, I would like to see IRCs that are proposed in the plan increased fourfold from two a year to eight a year. We have 750 miles of river to deal with.

Additional human considerations, if you would get these acres, you've got a floodplain, you've got wetlands, you have buffers, you have incubator areas for beneficial nutrients, all sorts of things.

And, again, I will submit my comments.

I ran out of time.

But, finally, there are numerous other issues that could be addressed easier with Alternative No. 2. A hybrid is suggested. But, most importantly, it would contribute most effectively to the health and heartbeat of the entire Missouri River ecosystem.

Thank you.

BILL BEACUM: Yeah, my name is Bill Beacum. I live in Sioux City, Iowa. Retired towboat captain. Special appointment to pallid sturgeon recovery team in 2004. Published a small booklet on the birds, 2003. Active on both counts.

I would like to caveat this, I'm not blaming anybody for the situation that we have here. Some of it goes back several colonels and several generals. It all started with the endangered species act, which gives the Fish and Wildlife Service unfettered authority. The Corps has to do what the Fish and Wildlife Service tells them.

Those of you who are operating under the assumption that we're deciding an alternative action for these birds and fishes are in a delusional state. We are not. We are only deciding a method of an action that's already been chosen, and that method only involves construction or some kind of management action.

If we were actually involved in doing something that included an alternative action, we would be looking at other areas in the basin for recovery, but the Fish and Wildlife Service, because it was very prescriptive, gave the Corps a job to do, and they did it.

And it goes beyond common sense to think especially in the bird situation, that you can recovery a metapopulation that covers five states, two Canadian provinces, in the wintertime most of the Caribbean, and two more states in the South that you could change anything permanently that only covers a 40-mile stretch of the Missouri River.

And as fantastic as it sounds, it is that fantastic. There's no way you can do it. And the Fish and Wildlife will say that the reason that it is different from the pallid - - or the piping plover recovery plan, which came out last year, is because it's a jeopardy, not a recovery plan. But then they will say, "But it will recover the whole species," which is a contradiction in facts.

So if you're going to do this, remember that they have only given us a selfish choice. Selfish choice: Do you want your child to live, boy or girl? You make the choice.

Everybody has gone for the No. 3, but for the bird especially, No. 3 does it better than anything else. And the truth of the matter, there won't be any money for any of it, so it would have been who, the Fish and Wildlife Service, when they presented the problem to the Corps to give them one that they could solve within the confines of their monetary ability.

And if we don't get on track, we have a congress up there now that's looking very seriously about undoing the entire endangered species act, and I don't think I want that to happen, and I'm hoping that

most of the people in this room don't want it to happen. So we've got to get our heads on straight if we want to move forward.

DONETTE JACKSON: Hi, my name is
Donette Jackson, D-O-N-E-T-T-E, J-A-C-K-S-O-N.

We live about seven-and-a-half miles east of Tekamah on a second-generation farm of 305 acres, all grain farming, in Burt County - - Tekamah, Nebraska, in Burt County. Our home is a mile and a quarter from the Missouri River.

I inherited the ground back in 2007 - - '05 - - 2005. My dad established the ground in 1956. In the 49 years that my parents lived on this farm, they only had one time when the water had reached their home, and this was due to a large ice jam that they had broke up with dynamite, and it didn't last four months.

We endured the 2011 flood. We were displaced for four months. We came back to a farm that was totally altered. It's amazing that we're still there.

In July of '15, the Corps put a pallid sturgeon shoot right next to our property. And they bought 190 acres, and they dredged - - we watched the process, and it took a little over a month, and they dredged all the sand out into the Missouri River. So now we have a very, very shallow river below us.

I would like to have you not change the master manual from where it is now with one of your alternatives. The spring and fall pulses will flood us again. And this will also interfere with the planting and the harvesting time.

We feel the unlawful taking of our ground violates the fifth amendment. We can't - cannot afford another flood. And it diminishes our hopes of handing down our farm to future generations. Your priorities are all wrong by accelerating the habitat development, changing storage and release protocol for the mainstream - - mainstream system.

Thank you.

JAREL VINDUSKA: My name is Jarel Vinduska, J-A-R-E-L, V-I-N-D-U-S-K-A, from Gretna, Nebraska. I'm a board member of the Nebraska Wildlife Federation, so I'm speaking on behalf of our board.

Wildlife is our issue, so we want the alternative that best promotes wildlife, and it appears that none of the alternatives are really great in that regard. Two is probably the best, but we would prefer a more ecosystem-wide approach to it.

But speaking on behalf of myself, I understand that the human concerns, just like the last lady mentioned, about the flooding and people that farm the floodplain, that's an issue that must be taken into consideration.

My first thoughts on that, since my career was in excavation, if we're going to artificially create nesting habitats and sandbars, artificially made sandbars, I just know, from experience, that the cost per fledged bird will be just astronomical and just a terrible waste of taxpayer money.

And I think that money could be well - - spent better to use to buy habitat. Or, in my mind, when I see how many birds are produced on some of these sandbars along the lower Platte River, much less money could be spent creating habitat off the river, buying and creating habitat, put sand out there, put water out there, put an electric fence to prevent predators from coming in.

And as far as taxpayer dollars per bird that you'd spend on a fledged bird, it'd be a lot less, I'm very sure.
So that's my comment. Thank you.

Correspondence Text

KAREN ROUSE: Good evening. Karen, K-A-R-E-N, Rouse, R-O-U-S-E. I live and work in Jefferson City and live in Columbia, Missouri.

I am the surface water chief for the water resources center of the Missouri Department of Natural Resources. The Missouri DNR represents the State of Missouri on interstate water issues. And I am Missouri's representative to the MRRIC. Thank you for this opportunity to provide comments on the Missouri River recovery program draft EIS.

Our message has been consistent. First, flood control and navigation are the primary purposes of the Missouri River system, and as such, the Corps must implement recovery program actions without preemption of fully accomplishing those critical and existing lawful uses of the system.

Secondly, several of the proposed alternatives would modify the flood control constraints of the system, which would require a change to the master manual. For example, under Alternatives 4 and 5, the flood control constraints are increased by at least 30,000 CFS. This action would be contrary to flood control.

Third, if the Corps were to consider changing the master manual, that would require a separate public process and cannot be embedded in any other process.

Should the Corps pursue a deviation to the master manual or a one-time flow event, it is imperative that the Corps consult with the governors of the states before implementing this high-consequence action.

Furthermore, the proposed flow events use water from the carryover storage pool, which is the pool we rely on during times of water shortage. The navigation flow support releases from the system benefit many uses on the lower river, such as water supply, energy production, recreation, and fish and wildlife.

In Missouri, over 3 million people rely on the Missouri River, or its alluvium, as its water source. Reductions in navigation flow support have cascading impacts, not only to uses on the Missouri River, but also on the Mississippi River, which is 40 percent of the flow to the middle Mississippi during normal conditions and peaked at more than 70 percent during the 2012 drought.

The department supports the Corps' intention to use natural flow events to improve our scientific understanding. In Missouri, the river is already highly variable, where it is known to rise 15 feet within a 12-hour period from localized rain events.

The 2011 independent science advisory panel noted that the natural rises had not been adequately or systematically assessed. Because of this, we believe that there is no need for additional water to be released from Gavins Point.

The State of Missouri supports the preferred alternative identified by the Corps in the draft EIS, with the exception of the potential one-time flow event. This one-time flow event was neither modeled nor was - - were the impacts assessed in the draft EIS because of the uncertainty of the hydrologic conditions present.

Given our high frequency of flood events in our state, we have always been very concerned about any proposed environmental flows from Gavins Point Dam that exceed flood control constraints. Let me be clear, the State of Missouri cannot support any alternative that includes environmental flows that exceed current flood control constraints.

The State of Missouri would also like to reiterate to the Corps that decision-making within the adaptive management plan needs to be open and transparent. All of the states represented in MRRIC agree that consultation and coordination with the states' governor's offices on matters of high-consequence is imperative.

Thank you again for this opportunity to provide public comments. The State of Missouri looks forward to further dialogue on this issue as the EIS process continues.

Correspondence Text

SCOTT OLSON: Good evening. Scott Olson, S-C-O-T-T, O-L-S-O-N.

I'd like to first thank the Corps for putting this meeting on tonight with parking passes at 5:00 o'clock rush hour in the heart of Omaha on Valentine's Day. You'd think you didn't want us here. Lucky for you guys it didn't snow, right?

Anyway, how do we put into words in three minutes the fear and uncertainty of what is to come with any of the alternatives discussed tonight. How do we plan for our future? How do we plan for the future of our children of whom we hope to pass down our legacy and all that we've worked a lifetime for?

Each and every alternative leads to destruction of the Missouri River as we know it. The flow events will continue to create floods along the river. The destruction of the banks by the Corps of Engineers has added to the degradation of the river channel, making it more prone to flooding.

This degradation also affects the water table in the region and along with flow events will render thousands of acres of prime land useless. Homes, infrastructure, taxes, jobs, and revenue that this country so badly needs will be lost.

The Corps of Engineers have become merely puppets, the strings to be pulled by Fish and Wildlife to do their bidding. Let's try a different alternative, one where we can coexist in the - in the basin, one where we can help the Corps rid themselves of this terrible monkey riding their back.

None of the alternatives are acceptable. Do not change the manual for any reason whatsoever. Fish and Wildlife and the U.S. - - and the U.S. Corps of Engineers have become terrorists in the hearts and minds of the citizens and stakeholders in the basin.

Thank you.

Correspondence Text

GEORGE CUNNINGHAM: Hello. My name is George Cunningham. I represent the Sierra Club. The Sierra Club is the nation's largest and most influential grassroots organization in the country with nearly two-and-a-half million members, and we have 25,000 members in the Missouri River basin.

The Missouri is one of the country's great rivers, indeed is the nation's longest river. The Missouri River was described by Lewis and Clark as a winding, meandering river teeming with fish and wildlife.

Today it has been altered by huge reservoirs and channelization that has removed the river from its floodplain. These changes have caused the loss of nearly half a million acres of fish and wildlife habitat, the listing of three species under the endangered species act, and made many native fishes, once common in the river, now rare.

Of the six alternatives presented in the EIS, we believe, that is the Sierra Club, the only environmentally sound option is Alternative 2, which will allow appropriate habitat types to be developed and move river management towards a more natural river that sustains wildlife and provides a more secure future for endangered species.

Also, Alternative 2 is the only alternative that links future management actions to the existing authority to carry out the bank stabilization and navigation mitigation program that restores over 165,000 acres of river habitat as the result of the modification to the Missouri River by the Pick-Sloan program.

Unlike some of the other alternatives presented in the EIS, Alternative 2 would not solely base habitat development on mechanically created restoration. Unfortunately, as currently written, Alternative 2 has proposed too many mechanically created sandbar acres thus inflating what we believe to be the true cost of Alternative 2.

Despite this overinflated cost, we support Alternative 2 with a reduction in the mechanically created

habitat, more in line with the other alternatives proposed by the Corps in the EIS.

One thing that we insist on is that the Corps link any proposed alternative to its existing authority carrying out the much needed mitigation of the past bank stabilization navigation activities. We believe the restoration of the nation's longest river should deserve the same attention and fiscal resources as the nation's other great restoration programs, such as the Florida everglades and the Chesapeake Bay.

Thank you.

MARK JONES: That's Mark, with a K, Jones. I'm from Rulo, Nebraska.

I'm here representing me, my family, and my family's future. We've been on the river since 1859. We've seen everything. We own approximately 1 mile of river front.

And so my dad 60 years ago was in front of a group like this fighting for the levee system, fighting for the Corps to make his life and generations after him better. I'm here trying to save it.

To the point, the six options, none of them work for me. Three of them will guarantee I'm done. Two of them, there's a 50/50 chance I can participate in farming that we've been doing for 150 years. One of them might work. I'm told that's the status quo, kind of what the last few years have been like, a couple years.

Two years ago, I lost half of everything - - no, two years, almost all of it, and last year half. And I've got the data to prove it, and that's not doing all this fancy stuff.

So it's not working, and nobody is asking us. The human side, those three little bullets up there, who's talking about us?

I could say a lot more. Three minutes is - - hey, I've done four briefings, and they don't work that way, sir.

So there should be a seventh one. At some point, nobody has ever asked me what do I think or what could I do about these three species that are endangered in this strip of ground.

And, yeah, I can't speak to the fish, because we used to catch them as kids; I don't do too much of that. But I'm out there all the time. I see the two birds. I grew up with those birds, chased them. Have you ever chased them, had your dog chase them?

They're not there anymore, and the reason they're not on our property, or north and south of me, is because the habitat is gone. And who took the habitat? I'm not going to say the Corps because, actually, I defend the Corps whenever I get into arguments.

The management system has taken away that habitat where we used to farm next to the river and all along the area, those birds were there, all kinds of them, going clear back when I was in first grade. They're not there now. That habitat is destroyed. It's gone. There's no place for them.

I run up and down that river. There aren't any sandbars there. Why? Because they're underwater for

months at a time. They never used to be when I was growing up. No birds were there. Now, hopefully the fish are there too.

So I'm saying let's have a seventh one. Let me have a chance. I hear it's about 50, 60 million we want to spend on one of these deals. Give me some of that. Let me clear that ground out. Let me put some places for those birds to be like they were when I was a kid.

The only place I see these birds now are inside my levee in ponds and pools that are created because the river is at the foot of our levees. They're there inside on farm ground that's been there for 100 years, but they're not outside where everybody thinks they ought to be because that habitat is destroyed.

So I wish you would consider a little more open approach to this and get the people that are there involved, rather than just giving us three minutes to express our feelings.
Thank you very much.

MARIAN MAAS: I'm Marian Maas, M-A-R-I-A-N, M-A-A-S, Bellevue, Nebraska. I am a retired biologist with focus in water quality and river and stream ecosystem restoration.

And I'm going to speak for the fish and the wildlife who, strangely enough, can't be here tonight. Quite understandably, they can't be here tonight nor can they submit comments anywhere along the line, so I'm going to speak for them.

First, I want to talk about Alternative No. 3. It is an all mechanical alternative, which means bulldozers and that type of thing will push sand around, and it is essentially the least sustainable and the worst alternative.

It has received a great deal of support by all the people who do not want flows in the river, who don't want to see anything change, and you have heard that tonight.

So instead of using flows on the river to produce sandbars, it'll be artificially done. The pallid sturgeon, the third of the three species, will have little benefit to be gained from this alternative, although they are creating what they call the IRCs, the interception - - oh, what is the - - rearing complexes.

And this is done on two wing dikes a year and over a span of about ten years, which is really, on the lower river, far too few and far too long of a time period.

Alternatives No. 4 and 5 probably don't get very much attention, but all the duck hunters and waterfowl hunters in the room or in the public should pay attention to these two because these provide a rise, either in the spring or in the fall, which increases the backwaters, increases roosting and feeding areas for migrating birds, eagles, waterfowl of all kinds, helps to bring in hunting, which is a huge revenue for towns and communities along the river.

And this is something that also is not mentioned. These rises help to replicate natural rises in the river and helps actually by filling these backwaters for other native species that are not being included in this, which is something that has been mentioned this evening, that we are only doing this whole plan for three species and all the others, such as the 67 native fish species which are declining or have gone, will not necessarily get any benefit. None of the plan is intended for other species.

Alternative 6 also should not be ignored. It is the old spring rise, and this duplicates what's been going on for eons. The river comes down out of the Rockies, there's snowmelt and spring rains, and the river rises. And this is true of all rivers to one degree or another.

So I know recent science that says that they may not get any spawning cue from that, but I think our science is not quite what we have yet to be able to test for that.

I would encourage Alternative 2. It is the amended biological opinion produced by the U.S. Fish and Wildlife Service, and I would like to see biologists in the Fish and Wildlife Service providing a description for what should be done, rather than - - please forgive me - - the Corps of Engineers.

I would also like to mention, as has been said this evening, that the BSNP mitigation needs to be in the final record of decision, and that it should be observed and acknowledged and plans clearly laid out for following it and getting it done in a timely basis.

Thank you.

DONETTE JACKSON: Oh, Donette Jackson, again.

I just would like to say that we have - - the river has been - - I mean, I can attest to this because I remember the '52 flood. Then I remember the channelizing of the river. It carried deep. It carried the water off.

Yeah, sure, we would have ice jams occur every once in a while, but they - - like I said, they would break them up with dynamite, and a sand - or an ice jam is far better than a four-month flood. You know, it - - I didn't think I'd ever live to see that along the Missouri River.

So I really hope that the Corps will listen to us and our concerns and that we can work together and try to - - just try to reach, you know, an agreeable solution to the problem.

The river has changed, and the notching of the dikes is a big - - a big thing because it's eating away the ground. And observing the one that was put right next to our property, it will - - before too long, it will be into our ag. property, our ground.

So hopefully they will listen and we can work together. Thank you.

BILL BEACUM: This gives me a little time to flesh the science out on the birds, and I'm not going to deal with the fish.

The piping plover has many opportunities for recovery. The thing about it is, we have chosen what is designated as a sink. A sink is a place where the habitat is not stable. And, generally speaking, when you recover any species, you go to a source. The source is a subpopulation that is not a sink and doesn't threaten the bird, and it can use it regularly.

We have source populations up on the alkali flats of North Dakota, which the people up there say they can have again the number of birds up there and make it consistent for less than a million dollars a year.

And one person even said for probably less than 100,000, and yet we're presuming that somebody is going to give us 200 million to do the same thing and not do it as well. And at the end of the time, we just have a status quo, according to the figures that they give us, and they can give us recruitment.

We're completely ignoring the saline lakes in South Dakota. The thing that started this whole thing was that, oh, if these birds don't nest in that 40 miles below Gavins Point, they won't nest at all. But the truth of the matter, that's a failed hypotheses.

The number of birds that are there now and the number that were there at the 2011 flood is zero to 1,832. You can't go from zero to 1,832 in five years, no matter what you do, unless the birds are coming in from different locations.

And the white paper that the Corps had worked with said there's only a 200th of a percent chance that this dispersal will take place, so that's bad science.

And the truth of the matter is that even if it wasn't bad science, you lose 20 percent of the birds through attrition every year. And if you don't have nesting for three years, you've lost 60 percent of the birds, and 60 percent of zero is still zero, so where do you build from if they're not coming in from other places?

Most of this science fails. And three scientists, the top people in the basin on the piping plover, one with the Fish and Wildlife Service and two with the USGS, have changed jobs now because they can't get other people in the Fish and wildlife Service to listen to them. And I think it's past time that the Fish and Wildlife Service people that are making the decisions start listening.

SCOTT OLSON: Scott Olson, again.
You know, we live and work in the basin - - here in the basin, and we've grown up next to the river. We've seen the wildlife that is there, and we know what needs to be done. Something needs to be done in places.

The flood of 2011 has destroyed more wildlife habitat up and down the river than it has ever created. It'll take many, many, many years for this to come back together.

You know, like I said, we farm down there. We've seen deer, turkey, pheasants. You name it. It's down there. But they're not there now. They moved out, and they're not coming back for a while, not until this habitat regrows and makes habitat for them.

But, right now, all you have is sunflowers and cottonwood trees and just junk down there. I mean, there's no food value down there. There's - - you know, they always say that birds live in trees. They don't live in trees. They live in the bushes, you know.

The work we've been doing down there, removing sand over the years, you don't even see birds along the river. The piping plover and all this stuff, like the other gentleman said from Southern Iowa/Missouri area, that's all been destroyed by the flood of 2011.

I know they built some huge habitats not too long ago south of us along the river. All of that is gone because of 2011. And they have come back in, and they've put over 3 million cubic yards of sand and soil into the river to create the sandbars that are out there.

You know, they were supposed to build, what, 170 acres of habitat for sandbars in three years from now. Is that right? Is that correct? Anyway, you're not supposed to answer. Anyway, let's do something different with it. But, you know, we all work for wildlife. We all try to leave our land a little bit better than the way we received it. We're doing our part, but I think the Corps is kind of falling down on theirs.

Work with the people in the basin, as he said over here. Come ask us. You know, we know the river. You guys are all experts. I guess you guys all know it better than we do. Give us a chance to work and get something done.

But stop the landgrab that's going on up and down the river because that's basically all it is, in my opinion, is just landgrab. 166,000 acres they want.

The river was channelized. There was 170,000 square miles that was put into production when that was done, and they're going to tear almost half of it out. I realize they want the basin back bluff to bluff, but there's a lot of people - -

Thanks for the yellow light. - - there's a lot of people that are really going to have a lot of problems with that.

I think the pushback on this is going to be very, very great, and I hope it is very great. I hope everyone in this room passes this on to someone else, and I hope that it goes just as far down the line, up and down the river, as we can make it work.

But everybody across the state of Nebraska, across the entire state of Iowa, Missouri, Kansas, everyone should be updated for what's happening and should be aware of what's happening because of the taxes, the infrastructure, everything that's going to happen.

And another thing you folks have not spoke of yet tonight was 500 floodplain - - the 500-year floodplain. I don't know if that has anything to do with this tonight. But, you know, we go from 100-year and 500-year and start paying insurance on that, and it's going to be kind of tough. Crop insurance, anything else, any federal money into these areas will be affected.

We've got a lot to learn, folks. Let's slow down and learn something.

MARK JONES: If I can say one thing?
I kind of beat you up for three minutes.

In all fairness to the Corps, it's been mentioned several times about 2011. That was a significantly huge, emotional event for me, but 2010 was almost just as worse, 2008 economically was just as worse. 2009, I lost half of it, and I don't know what we were doing then, recovering and getting ready for another flood, I guess.

But I've looked at these plans. A couple of them are devastating. If you go back and with particularly '10 and '11, in Southeast Nebraska, if we'd have had one 4-inch rain...

The data, I was - - I kind of looked at it before. I really looked at it last summer. We had a 1-inch rain. The river came up a foot. A 3-inch rain, it came up 3 feet almost overnight.

In 2011, we had 17 inches of freeboard left on our levee, 30-foot levee on the north end, and it never hardly rained through the 4th of July or even in June. And at a 2- or 3-inch rain, I wouldn't be here because the Missouri would have moved.

And I'm saying that in that - - don't take this personally - - what is the Corps' ability to manage some of these plans, particularly the three that really scare me. If we go back and look at 2011 - - and I've got the leads on that, read the emails, all the talk between Mississippi and Missouri and in the scuttlebutt within the Corps itself, it doesn't build confidence, sir.

If you adopt at least three or four of these six plans and you have an event remotely close to 2011 or 2010, I mean, just remotely close, and then we have rain associated with a flood like '84 and '93 - - see, those were bad floods, but what made them really bad was all the five rivers that were trying to cram into them south of Omaha and north of Saint Joe.

If you want a perfect storm, you not only have a couple bridges shut down, but our new bridge in Rulo probably would be - - the pilings would be unstable. My house would be gone, and it's been there since 1863. It would be gone.

So the risk, just as you would take it off and you'd weigh out this stuff with the risk, what is the risk of what can go bad, and I haven't seen any of that in any of the data. And I haven't read all 6, 7,000 pages, but there needs to be a risk factor. There needs to be a Paragraph 6, and I haven't seen that.

And me and at least two or three other people in here, we're the ones that are going to pay the risk, because if you lose the birds, that's tragic, but it sounds to me like we got other birds, and we can figure out how to replace that. But you lose me, my kids probably aren't going to fight this fight for 150

years like my ancestors have.

So that's what I - - we need to have a real discussion as to the total risk applied to each and every one of these options, and I don't see that anywhere. All I see is an argument. Is it good enough?
Thank you.

Correspondence Text

MR. LEPISTO: Good evening. I'm Paul Lepisto. Last name is spelled L-E-P-I-S-T-O. I'm a Regional Conservation Coordinator representing the Izaak Walton League of America, specifically the Izaak Walton League members in the states of South Dakota, Nebraska, and Iowa.

The Izaak Walton League of America thanks you for this opportunity to provide initial comments and for holding public meetings on the Missouri River Recovery Management Plan's Draft Environmental Impact Statement. The League is deeply involved in Missouri River recovery and many other river-related events and activities.

We want to thank the Army Corps of Engineers for extending the public comment period on the DEIS until April 24th. The DEIS is a massive and complex document running over 4,900 pages. The recovery actions outlined in the plan are for the federally listed species. But we feel those actions will also benefit many other native fish and wildlife.

The League is still currently reviewing the DEIS, and we will be submitting our detailed comments prior to the deadline.

Thus far, though, we have concerns on the Corps' preferred Alternative No. 3. This one utilizes mechanical construction to create shallow water habitat, interception rearing complexes and emergent sandbar habitat.

Our concerns primarily focus on future funding for recovery efforts that are outlined in Alternative 3. We ask what happens if funding for mechanical construction is not available or zeroed out by Congress. This has happened with other Missouri River efforts and programs in the past. Is there a Plan B contained in Alternative 3? If so, we haven't seen it in the DEIS.

Another important component we feel is missing in the DEIS is the mitigation program for the Bank Stabilization and Navigation Project. Mitigation is authorized in several prior Water Resource Development Acts, or WRDAs, but is seldom mentioned. We wonder what will become of habitat restoration goals and objectives in the BSNP Mitigation Program in the future. Also, how will the new Recovery Management Plan and the BSNP Mitigation Program be integrated.

The League supports and welcomes the Adaptive Management component of the plan. Under AM, recovery actions would be adjusted much quicker to provide needed benefits to the species.

We urge the Corps to robustly fund and support comprehensive monitoring and research efforts of any management actions undertaken. We feel this will help ensure the actions are performing and getting the desired response from the species. Additional research will hopefully close some of the data gaps and the uncertainty that currently exists in recruitment, especially for the pallid sturgeon.

In our preliminary review of the DEIS we favor many aspects offered in Alternative 2. This alternative re-establishes the floodplain connectivity and provides habitat for species and native fish and wildlife. Reconnecting the river to the floodplain in certain areas will also reduce flood risk, improve water quality, and increase recreational opportunities for families along the river.

We again want to thank you for this opportunity and we ask that you keep us informed as this process moves forward.

Correspondence Text

MR. IVERSEN: I'm Dana Iversen. My last name is I-V-E-R-S-E-N. I'm a Representative of the Stanley County Commissioners. I'm here for the - - the habitat that you've created for the animals probably is a really good thing the way they're doing it. The water levels in the Missouri, the lowering of the Missouri would actually benefit all the species that you're wanting to help. And what concerns us directly now is the water level of the Missouri being as high as it is at this current moment.

The lowering of the water will help; more sandbars for the birds, more longer drainage area from the dams for that sturgeon. So the elevation of the silt in the basins of these dams has created less storage for flood control in the lower and upper basin, and also has created, you know, less room for the fish and other animals.

The main thing that we're concerned about is the flood control and keeping that in check along with the helping of the animals. Thank you.

MR. RED CLOUD: Good evening. My name is Reno Red Cloud. The last name is R-E-D C-L-O-U-D. And I'm with the Oglala Sioux Tribe Water Resource Department. And I'm here tonight to make some comment from my department, and I know I've sat on the MRRIC, too, with the committee, but I just wanted to outline a few comments that I have from the Tribal Interest Group, the Oglala Sioux Tribe. I know that the Draft EIS and the Missouri River Management Plan focus on flows and habitat, but then historically with the flows of the Missouri River, our tribe has tribal reserve water rights. I wanted to make sure that them - - they are acknowledged and recognized.

And our cultural resources, before the dams were built we had natural flows. There were sacred trees that we used for ashes and medicinal plants that was part of our culture. The cultural resource aspect, I know that's modeled off to the flows, but then there's a lot more to it with, you know, our plants and animals, too, that affect our tribes, too.

And then the water supply, we have the Mini Wiconi Water Project just right out here, out of Pierre here that has had a intake that supplies water to three reservations; the West River, Lyman, and Jones, but we have a concern with that with water supply to that, that the water quality stays at a high level and that, you know, that it would not be affected by sediment.

Then the Oglala Sioux Tribe does have its own ordinance for tribal consultations. So whenever the time - - when we get done with our review and comment, when the tribal consultation does come, we have our own process through our tribal ordinance. And I know there's going to be two types of consultation, government to government, 106 NEPA consultations. We're looking forward to that consultation.

And then the Endangered Species Act, I know the least tern and the piping plover and the pallid sturgeon, but the tribes also need to be acknowledged with their water rights and the treaties of the Great Sioux Nation. And I know there's 29 or 30 other tribes within this, you know, this DEIS and Missouri River Management Plan, too, that I hope that they're being acknowledged and fully, how would you say, notified of the process, too.

And we are working with our THPO office, our Water Resource Management, Tribal Water Resource Management Team Programs, and we do have a biologist that we are going to be reviewing the DEIS

with. I know that it's a 5,000-page document, but we'll be getting our consultation topics with - - whenever the time is right for consultation. Thank you.

Correspondence Text

(Speaker 1 - Mr. Al Jacob - Speaking as
Chairman of MO Valley Levee District)

MR. AL JACOB: Well, I don't know exactly where to start. I am concerned that in 2011 we had a major flood event on the upper Missouri. And at that time, all the states were going to work together to try to not let this happen again. Well, now here we are six years later talking about having a surge possibly twice a year.

We're seven to ten days below the dams on the Missouri River. There's no way they can forecast the weather that far out, knowing what the rainfall is going to be in that time. And I feel that it's just a very dangerous situation to put us in. In our district alone, we have state highways. A flood event would split our school districts. Our availability for a hospital would be almost nil because we couldn't get to it, the closest one. We'd have to drive a half-hour to get to one instead of ten minutes.

I just - - I'm not - - I don't know if there's anything that can be done to help the pallid sturgeon and the birds, but I think we need to take care of the people first, consider what's going to happen to them and how it's going to affect their lives. For the State of Missouri, we cannot handle any type of surge. It's just totally out of the question.

(Speaker 2 - Mr. Robert Struckhoff - Speaking
 on behalf of Dorist Levee District and Augusta Levee
 Association)

MR. ROBERT STRUCKHOFF: I know I don't like the pulses, the pulses in the river where they raise them. On the lower end where we are at, we're a week to ten days from - - what's the name of that dam up there, the last one, Gavins Point. And they can't forecast the weather that good. Say there's a pulse coming down the river and we get a big thunderstorm and everything goes bad.

I just can't understand why these people - I feel a lot of this stuff comes from Washington, DC. I was up there a couple weeks ago. And I don't know. I don't think they understand rural America. That's what it seems to me, they don't understand.

And a lot of these things with the pallid sturgeon, you know, it's not scientifically proven that that will help them even. It's a good idea maybe. But they are going to put a lot of people's economy and stuff in jeopardy with these great ideas they get, and also cost quite a bit of money.

They could much use that money for the infrastructure of the Mississippi River, getting their barge systems and their inland waterways working. Otherwise we've South America down there. You know, they've got horrible roads, but they are starting to get their infrastructure good so they can move their economy to ports. That's what we need to do. I think that's about all I've got.

Correspondence Text

MS. JOSIE ERFLING: We, Wilmer and Josie Erfling, are farmers in the Missouri River Bottom in the Hermann, Missouri area. We are the fifth generation to farm this land. We feel and certainly believe that the Corps of Engineers has a duty and a mission and a moral obligation outlined by congress to provide flood control for the citizens of not only that area, but our nation.

The northwest division cannot turn its back on congress, and it's got to find a way to protect the species and still follow the mission of flood control. This is the directive that congress and it's the desire of the people, but it's not what this draft environmental impact statement sets out to do. Having spent over three-fourths of a billion dollars on two birds and a fish, it's time that they start to think about the human impact.

We have an area on our land where the Corps cut a dike, causing tremendous erosion. We lost sandbar habitat that now they are so desperately trying to gain. We are losing land, soil. It's going down the Missouri River. And we have intense bank erosion. It's time that the Corps start listening to the landowners and not just accepting what Federal Fish and Wildlife and the different environmental agencies can just plunk down in front of them. The Corps needs to get out and meet with the people who own the land and work the land use the land to the best of their abilities.

It's easy to take information that these environmental agencies can present before them, where the farmers, we don't have the time or the resources to give them this in a form that is readily available. They need to get out there and meet with us and stand on the bank of that river and see what it's doing.

We appreciate everyone's time. We appreciate the opportunity to speak before the Corps. And if there are any questions, we would love to have them come stand on our levee, take a look at what the river is doing to our farmland. These artificial spring rises and fall rises just are not an alternative. Thank you.

Correspondence Text

MR. TIM BRISCOE: Thank you. Good evening. My name is Tim Briscoe, and I'm a law student with the Interdisciplinary Environmental Clinic at Washington University. The clinic is speaking on behalf of the Missouri Coalition for the Environment, and our comments today center on the statutory obligations of the Army Corps of Engineers under the Endangered Species Act and the National Environmental Policy Act, or NEPA. In a moment, my partner, Gabby Riek, will make some comments on the alternatives analysis.

But first I'll discuss the way that the EIS frames its goals. NEPA regulations require the Corps to utilize a statement that, quote, briefly specifies the underlying purpose and need to which the agency is responding and proposing the alternatives including the proposed action, end quote.

We believe the purpose and need statement of the EIS does not make its goals sufficiently clear and, as a consequence, does not provide the public with a concise and focused set of objectives for the evaluation of the project alternatives. The Corps provides multiple and potentially conflicting goals in different sections of the EIS. For example, the executive summary states, quote, the purpose of the EIS is to develop a suite of actions that meets Endangered Species Act responsibilities for the piping plover, the interior least tern, and the pallid sturgeon, end quote.

The statement effectively summarizes the Corp's obligation to ensure that the continued existence of the three species is not jeopardized by Missouri River operations. However, the Corps adds within the problem definition section of the first volume of the EIS, rather than the executive summary, that the plans should continue to, quote, serve the Missouri River authorized purposes and accounts for human considerations, end quote.

The original purpose specified in the Endangered Species Act becomes subordinate to the EIS's lengthy discussion of human considerations, which consists largely of the economic effects on certain special interests. We are concerned that those considerations, which are not identified within the purpose and need statement, become controlling factors in the ultimate selection of the preferred

alternative. What gets lost in translation is how effectively the selected alternatives will actually meet species' goals relative to the other alternatives, or at least a clear statement to that effect at the beginning of the EIS.

Of course, the science associated with the three threatened endangered species is extremely complicated and inevitably carries some degree of uncertainty. That uncertainty, however, should not be used to obfuscate the intent of congress as embodied in Section 7 of the Endangered Species Act.

For those reasons, we submit that the Corps reconsider and clarify for the public the formulation of this purpose and need statement. Thank you.

MS. GABBY RIEK: Good evening. My name is Gabby Riek, and I'm also here from Washington University as a student consultant speaking on behalf of the Missouri Coalition for the Environment. I will speak to our concerns regarding the range of alternatives that are discussed in the EIS.

We believe the range is insufficient because a reasonable alternative could fall between Alternative 2 and Alternatives 3 through 6. The EIS analyzes in detail six alternatives to achieve project goals, including a no-action alternative, which is Alternative 1.

Alternatives 2 through 6 consist of other actions that will reduce the likelihood that the Corps' operation of the Missouri River system will jeopardize the continued existence of the interior least tern, piping plover and pallid sturgeon.

Alternatives 3 through 6 are very similar to each other, but very different from Alternative 2 which is based on the 2003 amended BiOp. Alternatives 3 through 6 differ slightly in the amount of mechanical emergent sandbar habitat, or ESH construction. They also differ slightly in the need for and timing of a flow release from upstream reservoirs.

But there are significant differences between Alternative 2 and the other alternatives. First, Alternative 2 requires far more mechanical ESH construction to benefit the interior least tern and piping plover. The goal from the 2003 amended BiOp is to create 11,886 acres of ESH. Alternative 2 achieves this by creating 3,546 acres of ESH per year at a significant cost. Alternatives 3 through 6 require only a fraction of this acreage, ranging from approximately one-tenth to one-fifteenth of that in Alternative 2. Unsurprisingly, Alternative 2 is significantly more costly than the other alternatives. It is also difficult to believe that the

Alternatives 3 through 6 would reach the goal of 11,886 acres of ESH on the Missouri River.

Under Alternative 3, the Corps would create ESH habitat only through mechanical means. But this is only a tenth of the acreage of Alternative 2. Alternatives 4 through 6 heavily depend on what are

described as annual flow releases to create ESH. But because the river must meet very specific conditions before a flow release occurs, the releases will be much less frequent.

The alternatives also dramatically differ in amounts of early life stage habitat construction. The BiOp outlines a restoration goal of 20 to 30 acres of shallow water habitat per river mile. Alternative 2 would achieve the upper end of this acreage target by creating a total of 10,758 acres of habitat. Alternatives 3 through 6 would create about a third of the habitat created in Alternative 2.

In addition, Alternative 2 includes unique management actions such as low summer flow and flood plain connectivity. On the other hand, Alternative 2 lacks the Level 1 and Level 2 studies' robust adaptive management and spawning habitat construction that are present in Alternatives 3 through 6.

For these reasons, we believe that the current proposed alternatives do not reach a wide enough range of feasible options to adequately protect the threatened and endangered animals. We believe that the Corps should include additional alternatives that fall between the endpoints of Alternative 2 and Alternatives 3 through 6. Thank you.

Correspondence Text

MR. TOM HORGAN: Good evening. My name is Tom Horgan, H-o-r-g-a-n, Senior Manager of the Midcontinent Office for the American Waterways Operator, or AWO.

The American Waterways Operators is the national advocate for the U.S. tugboat, towboat, and barge industry, which serves the nation as the safest, most environmentally friendly, and most economic mode of freight transportation.

On behalf of our members, I appreciate the opportunity to comment on the Draft Environmental Impact Statement for the Missouri River Recovery Management Plan. On behalf of AWO members, AWO staff has served as a member of MRRIC.

First, AWO supports the recovery of the endangered pallid sturgeon and the threaten leased tern and piper plover, and we strongly believe that these species can be recovered without changes to the Master Manual or any other major flow modifications to the mainstem reservoir system, which our members strongly oppose.

Of the six alternatives presented to us for review and comment, AWO supports mechanical sandbar habitat construction contained in each of the alternatives included in preferred Alternative 3. However, AWO strongly opposes the various flow modifications common to Alternatives 2, 4, 5 and 6. Low summer flow provisions in Alternative 2 will cause irreparable harm to the navigation industry by creating a split season on the Missouri River virtually killing navigation on the river. In addition to this, the low summer flows in Alternative 2 will have severe negative impacts on navigation on the Mississippi River from St.~Louis all the way downstream to Cairo, Illinois. During drought years, over 80 percent of the water flowing by the St.~Louis Arch comes from the Missouri River. These flows are necessary to keep this commercial superhighway open.

Alternatives 4 and 5 create unacceptable amounts of flooding risk in the spring and fall, increasing

downstream flood control constraints and doubling releases from Gavins Point for 35 days. Regarding Alternative 6, AWO opposes the implementation of a full bi-modal spring release because of the risks to flood control, its negative impacts to navigation, and the lack of science that confirms that these flows would necessarily facilitate the recovery of the species.

We believe the Corps' preferred Alternative 3 strikes the best balance between species recovery and human considerations. This alternative meets the species targets for birds while causing the least amount of impacts to stakeholders. Furthermore, we commend the Corps for their commitment to study the correlation between tributary flows and pallid sturgeon habitat.

However, AWO supports eliminating the one-time flow test or bimodal spring rise from the preferred alternative because virtually no science has been developed to prove its value. In fact, the Corps admits in the DEIS that no current scientific evidence indicates the greater magnitude bimodal spring releases would serve as a cue for aggregation and spawning of the pallid sturgeon in the lower Missouri River. AWO is also concerned that this one-time flow test could be part of a permanent flow regime in the future.

Finally, AWO is very concerned about the implementation of any preferred alternative under an Adaptive Management plan. Our members are particularly concerned with the section of the Adaptive Management plan dealing with management actions outside the Record of Decision. Whenever new actions are proposed or existing actions are modified, those changes must be subject to thorough review, including public comment and environmental impact statements under NEPA, and must be in compliance with the Master Manual.

AWO will be offering written comprehensive comments in advance of the extended comment period deadline, and we sincerely thank the Corps for extending the public comment for an additional 60 days.

Colonel, in closing, we thank you and the Corps staff for traveling the basin to hear stakeholders' thoughts and concerns on this important matter. Thank you.

Correspondence Text

MR. DAN ENGEMANN: Good evening. Again, my name is Dan Engemann, E-n-g-e-m-a-n-n. I serve as Executive Director of the Coalition to Protect the Missouri River. The Coalition is made up of a variety of interests and supports the congressionally authorized purposes of flood control, navigation, water quality and water supply. We also support endangered species recovery.

We appreciate the opportunity to comment on the Draft Environmental Impact Statement of which several of our members and I personally have been involved in as part of the MRRIC process.

The Coalition supports mechanical sandbar habitat construction contained in each of the alternatives. However, we cannot support various flow modifications common to Alternatives 2, 4, 5 and 6.

We too are concerned with low summer flow provisions in Alternative 2. It would cause harm to our navigation industry, as Tom said, creating a split season on the Missouri River and adversely affecting navigation flows on the middle Mississippi River.

These low summer flows have the potential to negatively impact water and sewer treatment plants, as well as power plants, creating problems with intakes and increasing the risk of failure to comply with the conditions of discharge permits.

We too believe Alternatives 4 and 5 create unacceptable amounts of flooding risk in the spring and fall to our farmers, increasing downstream flood control constraints and doubling releases from Gavins Point.

Regarding Alternatives 6, our members don't support the implementation of a full bi-modal release because of the risks to flood control, and the impacts to interior drainage are far too great.

The Corps' preferred Alternative 3 strikes a better balance, we believe, between human interests and species recovery. However, our members are concerned about the potential for flooding and impacts to interior drainage, as I just said, as part of a one-time flow test.

The Coalition supports eliminating the current bi-modal spring rise from the preferred alternative because, as Tom just mentioned, the lack of science that's been developed to prove its value. We applaud the Corps for their commitment to study the linkage between tributary flows and pallid sturgeon recovery.

That's a point that we've been making for quite some time. We appreciate that that is in Alternative 3. However, we question how the Corps can keep such an option on the shelf for nine to ten years in the future as part of this alternative knowing that river conditions can change during this time, making human consideration effects difficult to monitor.

Flow rises in other alternatives raise questions about how they will be implemented, and especially those actions that require amending the Master Manual. We oppose such revision because of the time involved, the risk to the species, and the potential for litigation during which time the species could decline even further. Should the Corps choose something other than Alternative 3, the process for creating flow changes needs to be clear to stakeholders and be aligned with the Master Manual.

And for the same reasons, any adaptive management actions could cause the same concerns, especially those outside the Record of Decision, and we urge those to be subject to thorough review, public comment, and be in compliance with the Master Manual.

The Coalition to Protect the Missouri River will be offering comprehensive comments in advance of the extended comment period deadline. We thank you for the extra time to review this lengthy document, and for traveling the entire basin to hear our concerns on this important matter. Thank you very much.

Correspondence Text

MR. ADAM JONES: Good evening. My name is Adam Jones. My family and I farm in St. Charles County, and I am here to represent Missouri Farm Bureau, the state's largest farm organization. Many of our members' livelihoods are tied to the Missouri River and, thus, we've been involved in management issues for more than two decades. We're grateful the Corps extended the comment period to April 24 and plan to submit more detailed written comments at a later date.

Many Missourians continue to believe common sense must be the foundation of our government's management decisions. We're hopeful the Trump Administration will recognize the shortcomings of current federal actions and hit reset button.

Almost a quarter of our state's counties border the Missouri River. A new study shows agriculture is vitally important in those 25 counties. Agriculture, forestry and related industries had an economic impact of \$34.6 billion in 2016. Agriculture's contribution includes \$21.2 billion in inputs, over 135,000 jobs, and \$2.8 billion in federal, state and local taxes.

We believe flood control and commercial navigation are priorities when considering authorized uses. Much of our state's drinking water comes from the Missouri River, and we support flows for power generation and continued close coordination with levee districts.

We will not support proposals that weaken flood control, initiate pulses, or reduce flows in the summer. We do not support the construction of chutes and oppose actions that could damage private property, weaken levees or lead to large quantities of soil being deposited into the river. Given past experience, we're skeptical of adaptive management and what we consider to be very expensive experiments.

For the reasons stated, several of the alternatives under consideration are non-starters. Given the prescribed flow modifications, we do not support Alternatives 2, 4, 5 and 6. Alternative 1 is a concern that it continues to allow for a bimodal spring rise and the construction of shallow water habitat.

While Alternative 3 does not call for shallow water habitat, it does require Interception Rearing Complexes, which those who know the Missouri River simply consider more hocus pocus. At a minimum, it will be important to work with landowners who could be impacted by the IRCs. Furthermore, Alternative 3 does not rule out flow modifications in years nine and ten.

Every man, woman and child in the U.S. currently owes over \$65,000 for their share of \$19.9 trillion public debt. We have to be cognizant of expenses associated with each of the proposed alternatives.

We're not asking to give up on any bird or fish, but common sense has to be part of the equation. The Endangered Species Act must be updated. Consideration of human impacts must come first, and no one should be held hostage by the views of personnel within the U.S. Fish and Wildlife Service, Environmental Protection Agency, or any other arm of government. Thank you.

Correspondence Text

MR. DANNY KUENZEL: Good evening. My name is Danny Kuenzel. I am first and foremost a farmer, but I have been involved in Missouri River issues for a long time. I also serve as secretary treasurer for the Missouri Levee and Drainage District, so I am very familiar with the effects levee districts face when they have too much water.

Some people think of us as farmers, but we are also businessmen. We are also conservationists and environmentalists because if we have to be over applying chemicals and fertilizers which harms the environment, that doesn't make economical sense.

Alternatives 2, 4, 5 and 6 could very well end up having a very disastrous effect on the Missouri River basin agriculture if implemented. There are some people here saying our levees are not feasible. But let me remind you, they protect a lot of infrastructure, including interstates, two-lane roads, bridges, railroads and pipelines, just to name a few.

If Alternatives 2, 4, 5 and 6 were to be implemented, what if it starts to rain a significant amount of water after the water has been released? It can't be stopped. So what are some of the potential impacts? A major flood or a prolonged flooding event? Some of the flows I see mean possibly three to five feet of water in Washington, Missouri where I farm. An engineering friend in Cape Girardeau estimates 1.5 to 3 feet of extra water on the Mississippi.

So what happens in a prolonged flooding event? Interior drainage becomes a major problem, which leads to my next point. When drainage pipes are closed, water within our levee system is unable to leave, which means the longer it goes on, the worse it gets. That's not only bad for agriculture, but it's also bad for the environment. This means possible leaching of chemicals and fertilizer into our river system. And I think everyone here would agree that clean water is our goal. It seems like we are always coming to meetings to discuss the environment. What about the other seven authorized purposes of the Missouri River? According to my estimates, we've spent over three-quarters of a billion dollars on habitat recovery with very little to show for what we've done. I think it's high time the Fish and Wildlife Service start working with people and stakeholders for a common goal and good of everyone. It's not just their river. It's everyone's river. And environmental restoration needs to be done with existing uses of the river.

Correspondence Text

MR. MIKE GARVEY: It's Mike Garvey. It's spelled G-a-r-v-e-y. Thank you, guys, for allowing us to speak. I'm going to try to present a point that what's good for the endangered pallid sturgeon is actually good for the taxpayer.

Over millions of years, the basin of the masterful Missouri River pulsed in a meandering erosion zone, back and forth, creating the bluffs, rich soils and the expanse of a level floodplain. Additionally, glaciers periodically scoured the basin. These pulsing forces shaped a diverse, sustainable, biologically bountiful ecosystem which depended upon water boundaries regularly transversing its large flood plain. Floods then were not fast and destructive, but actually gradually rose and fell and recurrently inundated the entire flood plain.

This flood pulse nourished all manner of wildlife, amended the soils, gave the fish and wildlife breeding grounds, a much needed pulse of life, and wildlife breeding grounds. Although it took millions of years, actually billions, for this basin to form, it only took about a hundred years for man to alter the Missouri River into its fast flowing narrow ditch, devoid of life and barges. Actually, the Missouri River is not really being used for transportation and it should no longer be a congressionally approved use or authorized purpose.

To think that we can recover enough spawning to reduce jeopardy for the endangered pallid sturgeon by only flawed attempts to increase shallow water habitat within the narrow existing channel is ludicrous. We must stimulate a spring rise and fall. And without doing that, we are essentially trying to open a clogged artery without oxygen or a surgical stint. These few minimally added costly side channels sloughs and alterations of management structure has already been shown to later sediment in, a further waste of taxpayer money.

The sad fact is that very few barges use this costly boondoggle today we call the Missouri River, yet we pay to maintain it with transportation to the jeopardy of the pallid sturgeon and our own increasing flood risks. If only the Corps had listened to Charles Ellet and James Buchanan Eads instead of blindly following General Andrew Humphrey with his shortsighted levee only plan. If only they would listen today. Robert Criss just reported a paper that the floodwater levels are increasing and rising along areas that have been profoundly channelized, flood levels have become progressively higher, from 1.2 to 1.9 meters.

For too many years, our taxes moneys have been spent repeatedly padding the pockets of the levee districts, barge industry and a few farmers, who actually took the very land by accreditation that was considered to be unsuitable for agriculture from the river's edge to grow corn and beans, the same crops that the tax payers repeatedly replaces, along with the failed levees and sand removal each time a so-called natural disaster occurs. Only we have the created the problem and cannot blame God as if

it were His fault.

The Corps have incredible abilities. We need their expertise to take a second look at how they manage our rivers. They may actually find that needed changes maintains their workload. But it will take humility and acceptance of criticism, which is not their forte. The levee breaks and repeated failures are desperately trying to tell us something, and it's not to declare another emergency to replace the same levees time and time again. Some levees should be set back and some should have controlled release structures placed using LiDAR elevation and GIS imaging. The Corps has the ability, but they must consult and reason together with a listening ear to the various agencies.

To accomplish any reduction in flood risks and improve the shrinking population of the endangered sturgeon, only the Corps can do this. Landowners must also keep an open mind to understand potential benefits. Private marinas, hunting, birding and fishing clubs are some of the cost effective alternatives, and wind up of losing just a little bit of corn and beans from the sand damaged soil.

Destruction and alteration - - this is from U.S. Fish and Wildlife - - okay. I just want to say thank you, and I really do think that if we can just work together - - this is the time for the fish to speak. This is not a time for all these people who've always been heard. Thank you.

Correspondence Text

MS. KAREN ROUSE: My name is Karen Rouse, R-o-u-s-e. I am the Surface Water Chief for the Water Resources Center of the Missouri Department of Natural Resources. Missouri DNR represents the State of Missouri on interstate water issues and I am Missouri's representative to the Missouri River Recovery Implementation Committee. Thank you for this opportunity to provide comments on the Missouri River Recovery Program Draft EIS.

Our message has been consistent. First, flood control and navigation are the primary purposes of the Missouri River System and, as such, the Corps must implement Recovery Program actions without preemption of fully accomplishing those critical and existing lawful uses of the system.

Secondly, several of the proposed alternatives will modify the flood control constraints of the System, which would require a change to the Master Manual. For example, under Alternatives 4 and 5, the flood control constraints are increased by at least 30,000 cfs. This action would be contrary to flood control.

Third, if the Corps were to consider changing the Master Manual, that would require a separate public process and cannot be embedded in any other process. Should the Corps pursue a deviation to the Master Manual for a one-time flow event, it is imperative that the Corps consult with the governors of the states before implementing this high consequence action.

Furthermore, the proposed flow events use water from the carryover storage pool which is the pool we rely on during times of water shortage. The navigation flow support releases from the System benefit many uses on the lower river, such as water supply, energy production, recreation, and fish and wildlife. In Missouri, over 3 million people rely on the Missouri River or its alluvium as its water source. Reductions in navigation flow support have cascading impacts, not only to uses on the Missouri River, but also on the Mississippi River which is 40 percent of the flow to the middle Mississippi during normal conditions and peaked at more than 70 percent during the 2012 drought.

The department supports the Corps' intention to use natural flow events to improve our scientific understanding. In Missouri, the river is already highly variable where it is known to rise 15 feet within a 12-hour period from localized rain events. The 2011 Independent Science Advisory Panel noted that the natural rises had, and I quote, not been adequately or systematically assessed, unquote. Because of this, we believe there is no need for additional water to be released from Gavins Point.

The State the Missouri supports the Preferred Alternative identified in the Corps - - identified by the Corps in the Draft EIS, with the exception of the potential one-time flow event. This one-time flow event was neither modeled nor were the impacts assessed in the Draft EIS, and I quote again, because of uncertainty of the hydrologic conditions present, unquote.

Given our high frequency of flood events in our state, we have always been very concerned about any proposed environmental flows from Gavins Point Dam that exceed flood control restraints. Let me be clear, the State of Missouri cannot support any alternative that requires environmental flows that exceed current flood control restraints.

The State of Missouri would also like to reiterate to the Corps that decision-making within the Adaptive Management Plan needs to be open and transparent. All of the states represented in MRRIC agree that consultation and coordination with the states' governor's office on matters of high consequence is imperative.

Thank you again for this opportunity to provide public comments. The State of Missouri looks forward to further dialogue on this issue as the EIS process continues.

Correspondence Text

MR. BOB PERRY: Hello. I'm Bob Perry, Perry is P-e-r-r-y. I'm an agriculture biochemist that has a laboratory that works with farmers. We do a lot of soil testing and nutrient analysis. And I want to bring up - I certainly agree about the comments about the flow and it's very important. And I'll pick a little different part of the problem.

When building the shallow water habitats or the IRCs, mechanical constructions involves taking the soil from the banks and putting it into the river. This soil is high in nutrients. The study in Volume 2 of the pamphlets or the booklets it says that a study's been done that says adding more phosphorus and more soil to the Gulf of Mexico will not increase hypoxia. Well, the goal isn't to increase hypoxia. It's to decrease it. And the more soil we put into the river, the less likely it is that we're going to decrease hypoxia. The goals have been to reduce phosphorus and nitrogen going to the Gulf by 45 percent. And when these projects are putting in enormous amounts of phosphorus, that can't be accomplished.

Another thing about this soil on these banks is they contain antibiotic resistant microbes, and that hasn't been taken a look at. And that going into the river and the water systems that we have in Missouri taking water out of it is something that should be a concern.

Lastly, for people to think that taking away the levees is a wonderful thing to do for this world, you've got to keep in mind that behind those levees we have farm ground. And when you look at 100,000 acres of farm ground, we're able to produce enough kilocalories to feed 1 million people for one year. There's a lot more at stake than just some fish and two birds, and that's got to be considered. Thank you very much.

Correspondence Text

MR. DAVID HUMAN: Good evening. My name is David Human, H-u-m-a-n. I represent the Earth City Levee District, the Riverport Levee District, the Howard Bend Levee District, and the Monarch Chesterfield Levee District, all levee districts located here in St. Louis County. My clients are in the business of flood control. Using Corps vernacular and risk reduction, we are opposed to any alternative that poses any increased flood risk.

Understand that St. Louis County is a major, if not the major, economic generator for the State of Missouri. These districts protect property and businesses that are a major economic generator for St. Louis County as well as the State of Missouri. These districts protect over \$10 billion of property, over 1,800 businesses, over 45,000 jobs. These areas generate over \$140 million annually in real property and sales tax, including over \$55 million annually to education and over \$35 million in sales tax to the State of Missouri.

We are, once again, opposed to each of the alternatives that includes any increased flow modifications that inherently increases that flood risk. I want to remind the Corps of their flood control mission. Thank you for your time this evening.

MR. DAVID STOKES: Hello, my name is David Stokes. I'm with Great Rivers Habitat Alliance, and I'm going to be revising and formally submitting my comments to you before the deadline. So I'll get that in. I appreciate the opportunity to speak very briefly tonight.

I primarily want to second the comments of the first two speakers from the Wash U Environmental Law Group who really requested and stressed a need for reconsideration of Alternative 2. I very much hope that there could be a modified Alternative 2 that can keep the very laudable goals of Alternative 2 in habitat construction and acquisition and flood plain connectivity.

I think that flood plain connectivity is so important. This river is not there to serve the interests of the barge industry and the levee districts. This river is there to serve all of us, to work for all of us, and for the animals and fish in it and around it. And a natural river is a healthy river. A natural river is a beneficial river for all of us, and we very much hope that Alternative 2 can be reconsidered by the Corps. And I'll be submitting these comments formally as well. Thank you very much.

Correspondence Text

MR. THOMAS BALL: My name is Thomas Ball, B-a-I-I, baseball, football, basketball. I'm a member of Sierra Club Missouri River Grassroots Network, and I'm here to comment on the Missouri River Management Plan, the size and the depth of the Management Plan Draft Environmental Impact Statement.

I'd like to thank the Corps for granting the additional 60 days for the comment period. It's 4,906 pages of the NEPA footprint and then 6,100 pages if you count the scientific stuff. We really needed the extra time to read it all.

Forty years ago, the Conservation Chair of the Dakota Chapter of the Sierra Club petitioned the Fish and Wildlife Service for an endangered species listing for the pallid sturgeon. At that point, natural reproduction of pallid sturgeon in the Missouri River was not occurring and had not been documented to have occurred in many years. That lack of naturally occurring reproduction and recruitment has not changed.

The petition called for a pallid sturgeon propagation program to capture and recover at least a portion of the genetic stock of this ancient species before it disappeared. The Pallid Sturgeon Conservation Augmentation Program, PSCAP, appears to be successful in maintaining the species' presence within the Missouri River basin. However, if supplementation efforts were decreased, the species would once again face local extirpation within several regions.

PSCAP has provided a source of hope that these fish may some day recover by increasing the numbers of pallids, but it's also revealed its own profound risks and vulnerabilities. This captive experimental population is completely dependent on continued federal and state appropriations in partnership.

Manually spawned fish from hatcheries sometimes exhibit fin curl, I won't go into the pronunciation of what it is, various viruses and parasites and a newly discovered virus that originated in the leopard

frog, but now also can infect the pallid sturgeon. While some of these disease risks are found in nature, others have an anthropogenic component. In some early cases, it appears the hatcheries may have mistakenly bred some hybrid species.

The current DEIS falls short of the expected mark in troublesome ways. First, the scope is, as we maintained during the scoping phase, too small. It appears to abandon pallid sturgeon, least tern and piping plover populations above Fort Peck and on the Yellowstone River. This abandonment occurs despite previous Corps environmental analysis and draft review documents that justified their work under the MRRP and spent moneys appropriated for BSNP mitigation in Montana. And I have the documentation for those EA's here.

Second, the scope of the DEIS appears to avoid the proximate causes of decline for these endangered species, continued operations, and maintenance through the bank stabilization and navigation program, and the reservoir dams that block pallid sturgeon mitigation to private downstream river settlement.

Further, the BSNP continues to cause harm to the ecosystems upon which these species depend. The creation of a self-scouring canal has promoted the degradation of the river bottom and caused diminishing waters to recede from previously connected backwater channels. While the previous mitigation plan for this continued destruction of the ecosystem is studied under Alternative 2, it is entirely absent from Alternatives 3 through 6, including the Corps' preferred Alternative 3.

Alternative 2 should be the selected alternative as it aims at creating greater improvements on the ecosystem upon which these species depend. It is clear from the decline of the 57 to 61 native species of fishes that the food web has been seriously impaired and the previous high rate production capacity of the river system has been cut off.

Reconnecting disconnected backwater channels should remain an MRRP program goal, and appropriations sought for this purpose under the EIS - - I see I'm out of time. I'll be using the park service to continue to submit comments, and also the Sierra Club will be submitting additional written comments. Thank you.

MR. RON HARDECKE: My name is Ron Hardecke. That's H-a-r-d-e-c-k-e. As a crop and livestock farmer in Gasconade County, I want to express the vital economic impact of the navigation and flood control in the management of the Missouri River. In addition, many Missouri communities rely on adequate flows in the river for drinking water and power generation.

The Bank Stabilization and Navigation Project created a reliable system to provide for navigation and a year-round water supply and, if operated properly, can provide adequate flood control.

However, over the last 15 to 20 years, we have spent nearly three-quarters of a billion dollars on the Missouri River Recovery Plan, which compromises the integrity of many of the intended uses of this system for the supposed benefit of a fish and two birds. It is still not known if these experiments have brought about the intended results. It is time that the needs of humans take precedence over these species. Before we spend any more money that we don't have, we need to reexamine our priorities.

Alternatives 2, 4, 5 and 6 are unacceptable due to the prescribed flow modifications. Alternative 1 still allows for spring pulses and shallow water habitat construction. Alternative 3 calls for yet another experiment for the pallid sturgeon and does not take out the flow modifications.

Again, I think it's time that we get back to the origin tended uses for the Bank Stabilization and Navigation Project. Thank you for opportunity to comment.

Correspondence Text

MS. NADINE BALL: Hello, I'm Nadine Ball, B-a-I-I, and I'm just myself. I'm here just as a citizen, I suppose. I'm calling - - I'm speaking - - I also haven't prepared things beyond what I've written while I've listened to the different stakeholders. And I thank you for the chance to open it up and allow this.

When I look through the Executive Summary, page 29, the chart of relative positive and negative impacts, I can understand fully well why the Corps would choose Alternative 3. It certainly makes sense given - - looking at each stakeholder including the environmental stakeholders in an overall picture.

That said, I think what I wanted to share is the idea that in the last 100 years it has been human considerations more than any understanding of the ecosystem benefits or an understanding of the impacts of human considerations that have always taken precedence.

I'm from St. Louis County. I've lived here my whole life. And I've seen in the last 25 years even development in the flood plains behind levees that did not exist when I was a child. This has - - this flies in the face of the most common sense understanding of how rivers work. So while I can understand the position of the stakeholders, the concerns for their livelihoods, I do think that we are at a point both in St.~Louis, both on the Missouri River, as well as very much in general that we need to begin to learn to work with the natural world rather than always considering technological solutions that benefit us to the exclusion.

The last part that I wanted to say was that this is far greater than two birds and a fish. This has to do with ecosystems, maintaining their integrity and maintaining the fact that they support us. So thank you very much again, and I appreciate the opportunity.

MR. TOM BALL: Tom Ball again. Thank you. I really appreciate it. I did have three more points to make, and I'll make them as quickly as I can.

In 2010, the Sierra Club - - well, let's see. There's continued harm to the ecosystem upon which these species depend. Okay, that was my second point.

Third, in 2010, the Sierra Club, national Water Sentinels, Missouri Coalition for the Environment, Great Rivers Environmental Law petitioned Fish and Wildlife Service for pallid sturgeon critical habitat designation on the Missouri River. This request was deferred by FWS based on a lack of resources and insufficient conservation priority number. I believe at this time it is time for the Fish and Wildlife Service and the Corps to reconsider and to designate a critical habitat and to incorporate it into the adaptive management plan.

Fourth, the economic analysis provided comparing the alternatives is deficient. It contains no commercial fishing data. This data would have been used to offset agricultural costs in replacing no crops with an agriculture equivalent. Regrettably, as fishing stocks have declined and crashed since the closing of the BSNP, the six lower states have made commercial catfishing illegal. Commercial fishermen have declined in number and their self-reported catches is smaller each year.

In 2012, the Corps estimated that the total expenditure on the Missouri River for the last 100 years was about \$38 billion in 2010 dollars for the last 100 years. 1 percent of that much amount is what we've spent to recover the species from the harms that that has caused.

Fifth, the skinny fish problem has been treated as a means by which the adaptive management deals with submission of new information. The pallid sturgeons are - - many of them are malnourished. They look anorexic. Sadly, this initial treatment shows that adaptive management as designed in the DEIS is not very adaptive. I'm concerned that other new information, even reasonably foreseeable information, will suffer the same slow grinding fate.

For instance, as the ecosystem continues to decline, additional species will be petitioned for ESA listing. The sturgeon chub and the sicklefin chub are endemic to the Missouri River and have been recently repetitioned for listing, the alligator snapping turtle, others are species of concern. Where in this DEIS is provision made for the addition of newly listed species to the consideration under adaptive management? I do not find it and it should be there. Thank you again for the extension.

Alternative 2 is best, but needs critical changes implemented. It provides the best opportunities for recovery of the three species and adaptive management practices over time. This option also includes recognition of the importance of connections to floodplains and includes the option of acquiring increased acres for habitat and mitigation.

Alternative 2 is the best option to move toward a more natural river which is advantageous for the three targeted species as well as other fish and wildlife species. The Corps incorrectly sets the cost of Alternative 2 as too high. The Corps has included too much mechanically created habitat in Alternative 2 which unnecessarily raises its cost. Also the Corps does not consider the crucial environmental services that would be provided by additional habitat acres over the years. Those services include flood risk reduction and recreation opportunities that contribute to the local economy.

Alternative 3, the Corps choice, is the worst of the choices. It relies only on manual, artificially created habitat which would require indefinite work and maintenance. Alternative 3 would lock the Corps into a substandard, costly plan. This DEIS should be subjected to scientific review and allow more time for public review and input.

The Missouri is one of our country's great rivers, described by Lewis and Clark as a mighty, meandering river teeming with fish and wildlife. Today, it has been altered by huge reservoirs, by channeling its banks and by loss of floodplain connections. These changes have caused the loss of nearly half a million acres of fish and wildlife river and riparian habitat.

Amid all this damage the Army Corps of Engineers is required by the Endangered Species Act to manage the river in a way that does not risk the survival of the Least Tern, Piping Plover and Pallid Sturgeon.

Among the choices in the Draft Environmental Impact Statement, Alternative 2 is the best alternative. Alternative 2 allows habitat acres to be acquired and moves toward a more natural river that will sustain wildlife and provide a more secure future for endangered species. The Corps should reduce the number of mechanically created habitat acres in Alternative 2 to lower the cost.

I am asking you to choose alternative 2 and work in the coming years to save these three species and restore more natural fish and wildlife habitat along the Missouri River. Let's do it for future generations!

Thank you!

Our names are Ivan & Sharan Woltemath and we live near Hamburg, Iowa. Our farm home is on the Missouri River bottom and farming is our source of income. The main stem dams were built for flood control and the levees are to protect our home and farmland, please remember this! We think alternative 3 would be the least harmful to us, but we do not support any spawning cue or ESH creating releases from Gavins Point Dam. We are opposed to any changes in the management of the Missouri River that would increase the chances of flooding or negatively affect the level of ground water and decrease or stop interior drainage.

Thank you,
Ivan Woltemath

My comments relate to two areas: (1) the Piping Plover metapopulation issue, and (2) the efficacy of mechanically constructed Emergent Sandbar Habitat (ESH).

(1) Piping Plover Metapopulation

In the 2000 BiOp, USFWS concluded that operating the System, operating and maintaining the BSNP, and operating the Kansas River Reservoir System, as proposed, would jeopardize the continued existence of the federally listed pallid sturgeon, interior least tern, and piping plover. In the case of the Piping Plover, since channelization, instances of breeding on the Missouri River itself, other than in the Gavins Point reach, have been rare to non-existent. Following major flood events such as 1997 and 2011, plovers have utilized naturally-formed ESH, but only for relatively short periods until such habitats became unsuitable, usually because of natural inundation from varying river levels, reduction in fledging success due to overcrowding, natural re-vegetation, and/or increasing access to predators (Anteau 2017). Attempts to create artificial ESH have had mixed success and have not contributed in any significant way even to the limited population of Piping Plovers using the Gavins Point site; there was no change in number of fledged Piping Plovers there from summer 2000 through summer 2009 (Figure 3, Duberstein 2011).

The charge in the 2000 BiOp, that operating the System would jeopardize the listed species continued existence, has proven to be the case; indeed, a case can be made that operations intended to reduce jeopardy have had the opposite or no effect. The inordinate focus on attempts to reduce jeopardy in the Lower Missouri River (Lewis and Clark Lake down-river to the Mississippi River junction) is a direct consequence of the belief in the 2000 and 2003 BiOps that Piping Plovers consist of several essentially separate sub-populations and that extirpation of any of these must be avoided at all costs. Indeed, the level of interchange of Piping Plovers between the sub-populations was estimated in those BiOps at only 2%, based on an essentially best guess by experts. At that time there were little or no data to support this, or any, estimate of interchange between sub-populations; it is only recently that such estimates have become available. Recent estimates are based on actual data from the Alkali Lakes and Missouri River reservoirs in the northern USA and southern Canada collected by Michael Anteau and colleagues at Northern Prairie Wildlife Research Center, Jamestown, ND Canada, and in Nebraska away from the Missouri River collected by the Nebraska Tern and Plover Conservation Group, Lincoln, NE. Even though these locations are at opposite ends of the overall Piping Plover range, the interchange data are remarkably consistent despite differing habitats. These studies estimate subsequent-year return rates of successfully-breeding adults at 86.7% and 61% respectively, and 49.9% and 21% respectively. Thus there appears to be widespread dispersal, presumably each year, of 50-79% of the one-year-old potential breeding birds. Although re-sight data are few, they are indicative of movement between the formerly-constituted sub-populations, even to the extent of at least one Nebraska bird reaching the Alkali Lakes in Canada. Of course, Piping Plovers have evolved for some 10,000 years on the Great Plains to adapt rapidly to changing conditions, natural or man-made. Examples of this adaptability are numerous. Lake McConaughy, on the eastern North Platte River in Nebraska is a prime example; during periods of low lake water levels, studies counted as

many as 245 nests (Peyton and Wilson, 2007). In high water level years such as 2016, only 10 adults and 9 nests were found when the lake was near full pool (Zorn and Wilson 2016). Anteau (2017) noted that dispersing young Piping Plovers in the northern parts of the species range showed a preference for margins of Alkali Lakes and Missouri River reservoirs. Similarly, extensive use of off-channel habitats (definition below) by Piping Plovers throughout their breeding range also illustrates their impressive innate ability to rapidly colonize newly-formed habitat from one year to the next. Thus, to summarize, current data indicate that there is one interconnected breeding population of Piping Plovers, characterized by Anteau (2017) as being More like a single population with many breeding areas than a meta-population. The overall population is maintained by a marked amount of dispersal, especially by one-year-old potential breeders, in the range of 21-50%. Because of this adaptability, I strongly recommend that the DEIS adopt the one population concept, and cease so-called jeopardy avoidance operations on the lower Missouri River. The latter are a good example of high cost-low return use of taxpayer dollars, implemented solely because of a drastically underestimated degree of dispersal by young Piping Plovers in the 2000 and 2003 BiOps. Further, I strongly recommend that the delisting process be completed for this species.

Definition of Off-channel Piping Plover Nesting Habitats

These are habitats, either naturally occurring or man-made, that lie outside the main channel of the Missouri River, including, but not limited to, the following: constructed river shoreline, oxbow lakes, alkaline lakes, river chutes, sand and gravel mines, meander scars, deltas, splays, levees, point bars and cut-banks, transitional upland fringe, reservoir shorelines and islands, and Missouri River tributaries. Based on documented use or predicted use based on scientific data, these habitats have the potential to provide successful nesting by the Northern Great Plains population of Piping Plover in the Missouri River Basin. Not included in this definition is Emergent Sandbar Habitat within the main channel of the Missouri River that is created by water releases from the main-stem Missouri River dams or by mechanical construction.

(2) Efficacy of mechanically constructed ESH

It is a travesty that millions of dollars have been spent on mechanically-constructed but ephemeral ESH, based on flawed BiOps from USFWS in 2000 and 2003. These BiOps were written essentially without any scientific data, but nevertheless USACE charged ahead with ESH and chute construction. Both have both turned out to be ineffective in contributing to the long-term populations of the three listed species, especially in the case of the Piping Plover and Least Ter (Figure 3-29, Missouri River Recovery Management Plan and Environmental Impact Statement (MRRMP-EIS), Volume 2; Figure 3, Duberstein 2011), and undetectably so in the case of the Pallid Sturgeon.

Indeed, the proposed MRRMP-EIS states Risk and uncertainty are inherent with any model that is developed and used for water resource planning. & Unforeseen events such as climate change and weather patterns may cause river and reservoir conditions to change in the future. Although the EIS states The project team has attempted to address risk and uncertainty in the Management Plan by defining and evaluating a reasonable range of plan alternatives that include an array of management actions within an adaptive management framework for the Missouri River. All of the alternatives were modeled to estimate impacts to fish and wildlife, I believe the proposed plan alternatives cannot in any effective way counter the vagaries of variations in river flow that have been and will continue to be experienced in the Lower Missouri River Valley. These vagaries are reflected in the highly variable census data shown in Fig 3-29 of the MRRMP-EIS, Volume 2, and will mask any effects of the plan alternatives. Thus, in my opinion the less done on the river ostensibly in order to reduce jeopardy the better; the futures of Piping Plover and Least Tern are not dependent on conditions on the Lower Missouri River.

Correspondence Text**Managing the Missouri for Endangered and Threatened Species**

The Missouri River Reservoir System is the largest reservoir system in North America. Management of the system is complicated by multiple and diverse interest groups and applicable laws.

Interest groups represent irrigation, flood risk, hydropower, recreation, water supply, navigation, fish and wildlife, cultural resources, and commercial sand and gravel dredging.

One of the applicable laws is the Endangered Species Act of 1973, which provides for the conservation of threatened or endangered species and their habitats. The U.S. Fish and Wildlife Service maintains the official list of threatened and endangered species.

Three listed species live in the Missouri River basin: the endangered pallid sturgeon, the endangered least tern, and the threatened piping plover.

The Missouri River runs over 2,300 miles from Three Forks, Montana, where the Gallatin River, the Madison River, and the Jefferson River join as its headwaters. It drains into the Mississippi River north of St. Louis, Missouri.

It was once "the turbid, rapid stream - the Missouri." That is how John Jay Audubon described it in 1843.

Now the Missouri River is slowed at six major reservoirs behind dams. Fort Peck Lake and Fort Peck Dam are on the river in Montana. North Dakota has Lake Sakakawea behind Garrison Dam and Lake Oahe behind Oahe Dam. In South Dakota, there are Lake Sharpe at Big Bend Dam and Lake Francis Case at Fort Randall Dam. South Dakota and Nebraska share both Lewis and Clark Lake and Gavins Point Dam.

This large reservoir system affects the three listed species.

Maintained by the US Army Corps of Engineers, this reservoir system has the capacity to store 72.4 million acre-feet of water. An acre foot of water can cover one acre to a depth of one foot.

Precipitation, snowmelt, hydrology, basin and agriculture drainage, and resource uses influence decisions about the level of each reservoir.

How can the Corps of Engineers operate the reservoir system without jeopardizing the listed species?

To answer that, the Corps of Engineers, in cooperation with the Fish and Wildlife Service, has prepared a massive Draft Missouri River Recovery Management Plan and Environmental Impact Statement with supplemental materials.

The plan offers six alternatives intended to help the three species.

Alternative 1 is the congressionally mandated no-action alternative. This do-nothing option is not acceptable as the Corps of Engineers recognizes demonstrated needs for management plans "informed by the best available science," including new scientific information about the species and their habitats.

The remaining options provide for variable amounts of mechanical construction of emergent sandbar habitat for the plovers and terns. The different water flow releases of the alternatives account for the variable amounts of mechanical sandbar construction.

The five remaining alternatives also include managing reservoir releases during nesting season to

reduce the chances of rising water taking nests, eggs, or chicks of the plovers and terns.

Furthermore the five alternatives support hatchery propagation of the pallid sturgeon and monitoring sturgeon population, as well as construction of early-life stage habitat in the lower river.

These are good basic measures.

But beyond that, where are provisions for designation of critical habitat for the endangered pallid sturgeon; for unbalanced reservoirs to address the situation at a particular reservoir; for the application of the best science currently available?

Habitat loss, fishing and caviar harvesting, entrainment and watercraft propellers, contaminants, hybridization, invasive species, and iridovirus all threaten the endangered pallid sturgeon. None of the alternatives provide adequate response. The pallid sturgeon requires shallow-water habitat.

Designation of critical habitat is necessary! The Corps of Engineers seemingly acknowledges that with the phrase "avoid jeopardizing the continued existence of pallid sturgeon or its critical habitats" ^[1] in the accompanying Draft Science and Adaptive Management Plan.

Perhaps having unbalanced reservoirs as a management tool in the Missouri River Mainstem Reservoir System Master Water Control Manual is adequate, but perhaps not.

To say that Alternative 2 - following the U.S. Fish and Wildlife Service's 2003 Biological Opinion projected actions - is the best alternative presented, and it is clearly is, is not to say that Alternative 2 is adequate.

A lot of science has been done since 2003, and that science should inform policy and practice.

The final document should include an improved best alternative, with more fairness in estimating the costs of the various alternatives.

In other words, the best is still to come. I hope.

U.S. Army Corps of Engineers
Omaha District
ATTN: CENWO-PM-AC-MRRMP-EIS
1616 Capitol Ave
Omaha, NE 68102

It has come to our attention that the U.S. Army Corps of Engineers, in cooperation with the U.S. Fish and Wildlife Service have developed the Missouri River Recovery Management Plan and Environmental Impact Statement. It is our understanding this plan would change the water levels and flows of the Missouri River. The Missouri River has been a staple in the past and more important than ever in moving large quantities of corn, soybeans, agriculture fertilizer, rock and gravel, sand, cement, fabricated steel, and large industrial equipment and machinery. Military equipment from National Guard facilities throughout the State of Missouri could also be moved by barge. This mode of transportation is by far the most cost effective and efficient method of moving these products long distances.

It is imperative the USACE reconsider the impact of the proposed plan and amend it so as to make real economic growth possible by having a minimum navigable draft level of nine feet for at least eight months, preferably nine months of each year. This is very important.

Relationships have been developed with both foreign and domestic business alliances. The newly widened Panama Canal offers us business opportunities we have never been able to pursue until now. Customers are wanting to buy products from our region of the country. We must be able to ship these large quantities cost effectively and in a timely manner. Barge transportation is the only viable solution to this new demand.

The Corps indicated in a recent meeting in Kansas City, they were ready and willing to assist in any way to make this a reality. Your commitment to making increased economic growth of barge

transportation the Missouri River a priority, is very important to our future.

Sincerely,

Gary Jungermann
Callaway County Presiding Commissioner

United States Army Corps of Engineers
Omaha District
ATTN: CENWO-PM-AC-Management Plan Comments
1616 Capitol Avenue
Omaha, NE 68102

Consolidated North County Levee District
comments on the
Draft Missouri River Recovery Management Plan
and
Environmental Impact Statement
in follow-up to the
February 16, 2017 Chesterfield, Missouri, Public Meeting

On behalf of the Consolidated North County Levee District (CNCLD) Board of Directors, our extensive membership, and one of the largest levee districts on the Missouri River and the Mississippi River, the opportunity to provide comments in follow-up to the February 16, 2017, Chesterfield, Missouri, Public Hearing related to the Draft Environmental Impact Statement for the Missouri River Recovery Management Plan is greatly appreciated. A representative of the CNCLD attended the Public Meeting, heard the Corps presentation, heard all the input provided, and has reported back to the District, allowing for comments to be provided.

In short, the CNCLD supports Alternative 3 - With a no spring rise. During the Public Meeting, an array of issues were conveyed as to why Alternative 3 is the recommended option. Corps officials repeatedly heard these comments. The CNCLD, a P.L. 84-99 partner with the United States Army Corps of Engineers, further, is in support of eliminating the one time test spring rise from the preferred Alternative 3. The CNCLD is concerned that a one time flow test could potentially become part of a permanent future spring rise, a potential flood risk to the CNCLD (L-15), a Federal-aid levee.

Alternative 3, as was conveyed repeatedly during the Public Meeting, provides for a balance between human interest and species recovery. However, as already conveyed above, agriculture interest within the CNCLD is alarmed about potential flooding and interior drainage associated with a one time flow test included with Alternative 3.

Many thanks to the United States Army Corps of Engineers for traveling to the region, and providing an opportunity for stakeholders to provide input, comments, and concerns.

Sincerely,

Kevin Machens
President
Consolidated North County Levee District

U.S. Army Corps of Engineers
Omaha District
ATTN: CENWO-PM-AC-MRRMP-EIS
1616 Capitol Ave
Omaha, NE 68102

It has come to our attention that the U.S. Army Corps of Engineers, in cooperation with the U.S. Fish and Wildlife Service have developed the Missouri River Recovery Management Plan and Environmental Impact Statement ("the Plan"). It is imperative the United States Corps of Engineers reconsider the impact of the proposed plan and amend it so as to make real economic growth possible by having a minimum navigable draft level of the Missouri River in the vicinity of Callaway and Cole Counties of nine feet for at least eight months, preferably nine months, of each year. This is very important.

It is our understanding this plan would change the water levels and flows of the Missouri River. The Missouri River has been a staple in the past and more important than ever in moving large quantities of corn, soybeans, agriculture fertilizer, rock and gravel, sand, cement, fabricated steel, and large industrial equipment and machinery. Military equipment from National Guard facilities throughout the State of Missouri could also be moved by barge. This mode of transportation is by far the most cost effective and efficient method of moving these products long distances.

Relationships have been developed with both foreign and domestic business alliances. The newly widened Panama Canal offers us business opportunities we have never been able to pursue until now. Customers are wanting to buy products from our region of the country. We must be able to ship these large quantities of products and materials cost effectively and in a timely manner. Barge transportation is the only viable solution to this new demand. Highly regarded captains, tugs, and barge providers are already in place to ensure these very sizeable business transactions are completed on time and with the highest degree of professionalism.

The Corps indicated in a recent meeting in Kansas City, they were ready and willing to assist in any way to make this a reality. Your commitment to making increased economic growth of barge transportation the Missouri River a priority is very encouraging.

The below signed entities are in agreement in our request that the Corps of Engineers continue to consider the importance of the Missouri River as a transportation opportunity by ensuring the United States Corps of Engineers reconsider the impact of the proposed Plan and amend it by having a minimum navigable draft level of the Missouri River in the vicinity of Callaway and Cole Counties of nine feet for at least eight months, and preferably nine months, of each year.

Sincerely,

Roger Fischer

All of the alternatives proposed by the U.S. Army Corps of Engineers and the U.S. Fish and Wildlife Service regarding the Missouri River Recovery Management Plan are far too damaging to flood control of the Missouri River and far too risky for the ecosystem along the Missouri River. Two events in recent history have lead me to believe that statement.

First, in 2005 the Missouri River Recovery Program was initiated changing the management of the Missouri River. Second, the devastation of the flood in 2011. Since 2011, I no longer see fox and wild turkey in the Missouri River basin in Fremont County, IA. Deer populations in Fremont County, IA river basin were devastated by disease resulting from the 2011 flood. In a flawed attempt to save 3 species along and in the Missouri River, the U.S. Army Corps of Engineers and the U.S. Fish and Wildlife Service have endangered the whole ecosystem of the river and the people who live and work near it. After a decade of attending public comment meetings similar to the one held on February 14, 2017 in Omaha, NE I have become more concerned that pleas for improved flood control are falling on deaf ears. All proposed alternatives will damage wildlife, infrastructure, cities, farms, and families along the Missouri River. The U.S. Army Corps of Engineers and the U.S. Fish and Wildlife Service can do better and provide flood control to all that live along the Missouri River.

Please implement Alternative 2 of the Missouri River Recovery Plan. It is imperative that habitat be provided for the pallid sturgeon, interior least tern, and Northern Great Plains piping plover.

The Wildlife of this river and of our country are one of its greatest assets. Creating and preserving habitat for these species will of course provide habitat for countless other species.

Thank you for your consideration. Generations after us will be grateful.

Brian Yochim

U.S.Army Corps of Engineers
Attn: CENOW-PM-AC Management Plan Comments
1616 Capitol Ave.
Omaha NE 68102

We are writing in regard to plans for the Missouri River recovery.

Our family has lived in this area long enough to remember the floods that created what we now refer to as "the bottom land". We have pictures of a small boat being launched from Highway 75 between Herman and Tekamah into the flood waters that were lapping against the roadway. It has always been our understanding that the changes that were made many years ago to the course of the Missouri River were designed to control this very thing and, over the years, the plan has been largely effective.

In 2011 we watched as floodwater consumed the farms located all along the river as a result of the Corps of Engineer's genius plan to save some endangered wildlife. The results of that flooding were catastrophic, as you well know. At that time, if someone wanted to start a verbal brawl, all they had to do was mention the Corps of Engineers. And now we learn that the Corps is at it again! Really!

We are not opposed to wildlife management. We are not opposed to reasonable efforts to protect endangered species, but is anyone taking into account that the American family farmer is an endangered species that could use some consideration as well? Does it make any sense at all to protect the shoreline nests and the water habitat of birds and fish when that protection comes at the expense of a human's livelihood? Is it right to let a farmer's land and home literally "go down the river" to save some birds and fish?

We admit to not knowing much about the manuals and rule books of the Corps of Engineers, but we do know that those rules and regulations ought to be subject to correction when they obviously are not working. Surely, among the powers that be there are some with common sense and the vision to see where priorities should lie. We appeal to you to listen to the voices of the people- -those who are struggling to stay solvent under the best of conditions and who should not be undermined by officials who, at least on the surface, seem determined to do so.

Thank you for your attention to our thoughts on the subject.

Sincerely,

John G. Potadle
Sharron G. Potadle
20668 U.S. Hwy 75
Herman, NE 68029

Attn: USACE and U.S. Fish and Wildlife Services

There is a lot going on along the Missouri River to do with the habitat mechanical construction regarding the Endangered Species Act of 1973. The Fish and Wildlife Services have billions of dollars to spend and the corps is doing the work. This is truly wasteful spending! This money could go a long way to pay down our deficit.

In the meantime the Missouri river is more flood prone ever since 2004. The corps is suppose to maintain the river by protecting the real endangered species (human beings) from flooding and the wonderful productive rich farm ground that borders the Missouri river. The birds have found another home on the Platte River.

In 2010, 2011, 2013, and 2014 our farm ground flooded. There is something drastically wrong when we endure frequent floodings such as this. The priorities of the corps are all wrong. We have lost a lot of crop to these flood events. This is our livelihood plus the clean-up and having the topsoil removed sets the farmer back. It takes years to gain back that production.

In 2009, the corps bought 190 acres from the Papio Missouri River NRD that adjoins our farm ground to the south called Little Sioux Bend. In August of 2015 a double looped pallid sturgeon chute was constructed. We watched the process and all the sand was dredged out into the river. We now have a higher water table which is up and down the river where these chutes were constructed. Along with this process the rock dike was notched and there is a great deal of bank erosion going on. This notching has been done by the corps up and down the river. The aerial view tells the whole story. Our farm ground is very close to this area. The corps need to come back ASAP to fill in the dike with rock. We lost 30 acres to the north of this area to the 2011 flood. This 30 acres is covered with 15 feet of sand, covered with trees, and weeds. This piece of ground will never be farmed again. We are still having to pay taxes on this wasteland. The corps can purchase ground and it is tax exempt. This is so wrong!

I don't see how you can sleep at night knowing the results from all the alterations you have made to the river. You have totally deviated from the main purpose of protecting us from flooding because of money. The dikes have worked for decades and would continue to keep the water out in the channel.

We are paying higher taxes and the corps can buy up ground along the river, tax exempt. Two years ago our taxes in Burt county took a 30 percent increase. This year it went up another 10 percent. Commodity prices are low. Now you want to flood us again?

The truth is that we can not endure another flood. Beside living on a second generation farm,

this is our livelihood. Because my dad bought this farm back in 1956, owned a construction business, cleared the 54 acres of trees down by the river, left 34 acres to wildlife planting switchgrass, leveled the upper acres, and built a home makes this family farm so special to me. I know how much time and money he put into establishing what he loved doing the best and that was farming. The people were told to clear the ground and farm it because the river was channelized and the dams were in place to protect them from flooding.

As I said before, this is our livelihood and by notching the dikes, that are causing bank erosion, you are unlawfully taking without compensation which is violating the 5th amendment.

I flew with a friend a couple days ago and took pictures. You get a whole different perspective from the sky. These pictures show what is happening with our river. Where the chutes were put in there are sandbars in the middle of the river. The river is much wider now. Where the dikes have been notched, the banks are eroding back toward the agland. All of this is bringing the river closer to our private property and not if, but when the next flood comes, it will come up so much quicker and cover more ground than it did in 2011. This scares the hell out of me!

I know that you have viewed your projects from above and can see what damages you are bringing to all the businesses, homesteads, towns, and agland. This Missouri river does not resemble what once was. You need to listen to us, we need to communicate, and work together for a better cause.

Because of the huge amounts of sand and debris in the river's stream our water table is higher on the lower river south of Gavins Point Dam. If you put any three out of the five alternatives in place using the spring and fall pulses, that could raise the river levels by as much as 5 feet or more in most places. This kind of raise will flood us again! This would also be the time of planting crops or harvest. We are still trying to recover from the 2011 flood so don't throw another one at us. If you had let water go in January, February, and March of 2011 making storage room in your reservoirs, we would not have suffered the huge destructive damages that incurred. I'm asking you not to change your master manual.

P.S. I would like to express my thoughts on the open house and hearing. Who has ever heard of not being allowed to ask questions in front of all who attended the hearing. The definition of hearing is: the ability to hear, chance to be heard, formal meeting to hear testimony. All present were there with the same concerns. Then stating that we only had three minutes to talk. Who, of any of us that spoke, pre-timed their talk?

Pallid sturgeon reproduction is poorly understood. Alternative 3 or 6 seem to provide the best chance for further Pallid sturgeon study with the least adverse effect on all parties using the Missouri River.

I do not care about endangered species. The river water level should be kept low, so that farmers can plant crops. Raising the water level can delay planting of crops and is criminal, and I wish that unnecessary and evil government interference could be prosecuted, even prosecuting senators, and congressmen for their evil laws.

My name is Del Husz, I live at 50411 Ashton Road, Glenwood, Iowa 51534.

I have been a farmer on the Missouri river bottom all my life. I have also served on the Pony Creek drainage district board and the M&P levee district 611-614 for many years. I have been to numerous meetings on levee safety and levee repairs throughout those years.

I am concerned with the situation that I see going on with the mitigation of endangered species on the Missouri River.

By proposing such a wide range of alternatives or options it appears to me that you are only guessing at what may save the endangered species. There should be proven science behind these options before implementing any of them. Any excess water stored behind the dams to implement your alternative or option is a flood risk. You are unnecessarily risking lives and property with these plans. I believe the most important consideration in this project should be flood control to protect the businesses, personal properties, farmland and human life that has flourished along the river for many generations. That was the number one reason the system was built in the first place and it should still be the number one reason to maintain it. If even one person were to lose his or her life due to unnecessary flooding of the river it would be too high a price to pay just to potentially save our endangered species.

As a farmer I rely on the Missouri River for my farm's water drainage! It is the main component of all our interior drainage systems which consists of field ditches, road ditches and creeks. Any slowing down of flow or restriction on the Missouri River affects all of the rest of this system. Your proposed flushes will create a high river event which will cause a situation where nothing else will drain or flow for miles inland from the river. This creates a situation where it is impossible to farm and raise a crop. Please consider these comments and remember your actions affect thousands of farmers, businesses and homeowners along the Missouri river bottoms.

Thank you.

Del Husz

Public Comment Letter to the USACE (Corps of Engineers)
In Regard to the Missouri River Draft Environmental Impact Statement
Released December 16, 2016

Dear Colonel:

I, Diana Spotted Horse, as an enrolled member of the Standing Rock Sioux Tribe would like to provide comment to the Draft Environmental Impact Statement (DEIS). As a tribal member of Standing Rock my family has been personally and economically impacted by the development on the Missouri River since the dams were first built. The water rights of the Tribe are being detrimentally impacted by the DEIS.

As a member of the tribe I am opposed to mechanical construction in the Oahe reservoir. I am also opposed to the type of development which would impact the water quality or quantity. The water rights and water supply issues directly impact me as a tribal member. The plants, including medicinal and those which are important to the spiritual and cultural lifeways of my people are at high risk due to the development and resulting pollution along the length of the river.

I would like to submit this statement to the Corps of Engineers as a record of my concerns about the Missouri River (Mni Sose). Please add a section called Tribal Concerns to the Adaptive Management Plan (ADMP) preferred alternatives. There should also be a dam removal alternative added to the DEIS.

Please accept my comments into the public record.

Thank you,
Diana Spotted Horse

The implementation of the alternatives proposed in the Draft Missouri River Recovery Plan and Environmental Impact Statement have the potential to be costly to not only the United States tax payers that provided the funding for such projects, but also to industries that rely on the Missouri River for transportation of commodities and oversized equipment and also of course to the species that these plans seek to protect.

As a representative of not only agriculture, but of the navigation industry it would be imprudent to not respond during a public comment period. Unfortunately, the technically report for just the navigation portion alone is 66 pages, with entire document coming in at over one thousand pages. As a result, those that actually respond during such comment period are those with the time to plow through such a data dump. The term data dump appears harsh at first blush but on closer inspection may be generous.

One would assume that the issues involved, that being the survival of a species such as the pallid sturgeon, the survival of an industry such as navigation that relies on appropriate management of the system or agriculture that has thrived and become one of our nations largest economic drivers behind levy systems at risk by proposed alternatives would be addressed with the utmost care a scrutiny. Yet if responses are not made to address the specifics in these piles of documents then the powers that be proceed at will, waving their massive documents as proof of theories and expertise.

I am not a scientist, Im an Agribusiness manager, so when I start working my way through the 66 pages of the Navigation Environmental Consequences Analysis Technical Report, I was only on page six before I realized that I may be only the second person to have ventured that far in a straight read through. Otherwise, how would you get sentences like this one that is pulled directly from page six. Please note I have made no changes to punctuation or capitalization.

While this it cannot list the assumptions used to generate the transportation savings function These transportation savings functions represent the transportation rate saving For additional material discussion on assumptions please review this document.

I then glanced to the bottom of the page and note that every single one of the 66 pages of the Navigation Environmental Consequences Analysis Technical Report is titled Irrigation Environmental Consequences Analysis Technical Report.

The last project proposed to act in support of the pallid sturgeon involved creating shallow water habitats. During the public comment period of this 80 million dollar project, I suggested that these shoots might want to be rethought, that while Im not an engineer, common sense would assume that water will take the shortest course. I was condescendingly explained to that they had models and research on their side. As it ended up all those dollars later, the shallow what habitat was running 35 deep and pushing silt into the main channel creating a 7 shipping channel. Those tax payer dollars did

nothing to serve navigation, agriculture or the pallid sturgeon.

What happens when you strive to get this type of mismanagement stopped? The property across from our dock has been purchased for inception rearing complexes. Im sure its coincidence.

In short, we would opt for Alternative #3 as proposing the least harm to all involved, including navigation, agriculture and the pallid sturgeon, but sincerely and respectfully would request that more care, expertise, good science and common sense be involved in make these decisions.

It seems approach for evaluating navigation consequences of the MO River Recovery Management Plan and the methodology and assumptions for the analysis on the impacts to navigation are flawed. The analysis of Water Compelled rates relies on very old data and is insufficient to say the least.

As an industry, we do want wish the harm or endangerment of any species on our back, but throwing money at unproven science and calling it adaptive management is less than prudent. Risking the loss of jobs in an area that is currently 10% over capacity according to MoDOT on rail capacity is not economically responsible. Nor is having the tax payers pay 3 times the going rate for land across from our dock to rub our nose in the next adaptive management project.

We would also request that when considering National Economic Development and impact that we remind ourselves that the waters from the Missouri River do not and have never stopped at the arch in St. Louis, nor do the tonnage coming off of our system, and that while a per ton mile is evaluated, those same tons go all the way to the gulf almost without exception. The water supplied by our system effects the nation as a whole impacting the Mississippi River and while that doesnt fit into the formula of the eight authorized purposes of the Missouri River, it is real and common sense should not have blinders.

Giving the appropriate priority to Flood Control and Navigation increases and support the economics of our country with in turn creates the tax basis that can then be used to support our environmental stewardship.

The eight authorized purposes are appropriate services for our system and should be each supportive of the other.

Thanks for the opportunity to participate.

Correspondence Text

Dear Brigadier General Spellmon:

The State of North Dakota agencies with Missouri River responsibilities have reviewed the Missouri River Recovery Management Plan and Environmental Impact Statement (MRRMP-EIS) and submit the attached comments. The state looks forward to continuing to work with the U.S. Army Corps of Engineers (USACE) on further development of the MRRMP-EIS and implementation of adaptive management. This partnership is critical in ensuring that sound decisions are made for the good of all that rely on the Missouri River in North Dakota. To be a true partnership, the final EIS should provide for direct consultation with North Dakota, and other affected states, for consideration of flow modifications or deviations outside the bounds of the current Master Manual. It is also requested that the USACE incorporate their responses to comments submitted for the MRRMP-EIS in the final EIS. Thank you for the opportunity to review and provide input into the MRRMP-EIS.

Sincerely,
Doug Burgum
Governor

Missouri River Recovery Management Plan and EIS
State of North Dakota Comments

The following comments are strictly based on the State of North Dakota's evaluation of the draft Missouri River Recovery Management Plan and Environmental Impact Statement (MRRMP-EIS), and supporting documents. North Dakota reserves the right to submit additional comments on any future changes or additions to the MRRMP-EIS not disclosed in the draft documentation made available for comment at this time. It is also requested that the U.S. Army Corps of Engineers (USACE) incorporate their responses to comments submitted for the MRRMP-EIS in the final EIS.

The MRRMP-EIS contains a number of shortcomings that are of concern to the State of North Dakota. Among those are that it fails to consider a reasonable range of alternatives under the National Environmental Policy Act (NEPA): the only bird habitat management options evaluated in Alternatives

1 through 6 are really just "sub-alternative" variations in pursuing a singular approach of Emergent Sandbar Habitat (ESH) creation through mechanical and flow means, rather than being inclusive of other bona fide alternative habitat approaches for the birds. There is also confusion in the underlying purpose of the MRRMP-EIS. That purpose is stated to be the avoidance of jeopardy (executive summary, p. i); however, it is called a "Recovery Management Plan" and the species objectives appear to be recovery-oriented insofar as they support stable or improving trends. The MRRMP-EIS is also dependent on numerous models. Depending on the rigor of models, their output can give the appearance of objectivity and specificity where it does not necessarily exist. It is unclear from the document whether (and at what level) the various models have been subjected to scientific review, verification and refinement. The models have not been made available for review, nor were state experts who have local knowledge and experience the USACE lacks consulted regarding the models. However, even with these shortcomings, North Dakota tentatively supports the Preferred Alternative under the following conditions:

- (1) Reconvene consultation with the North Dakota Interagency ESH Team on annual activities related to the Missouri River Recovery Program;
- (2) The final EIS and Record of Decision (ROD) state that any flow modifications outside the bounds of the current Missouri River Mainstem Reservoir System Master Water Control Manual (Master Manual) would require the preparation of an additional EIS, including consultation with affected states; and
- (3) The final EIS commits the USACE to obeying all applicable state laws, permit and regulatory requirements, and policies. Further explanation of these conditions is provided throughout these comments.

North Dakota's tentative support of the Preferred Alternative (Alternative 3) is based on the unacceptability of Alternatives 2, 4, 5, and 6 due to the adverse impacts those alternatives would cause. In addition, the potential model deficiencies are less likely to understate the impacts for Alternative 3 than for the other alternatives.

With respect to general comments, the State of North Dakota offers the following:

Master Manual-related Concerns

The State of North Dakota has serious concerns with respect to potential changes to or deviation from the Master Manual. The MRRMP-EIS includes alternatives with several flow management actions that would deviate from the current Master Manual. The Adaptive Management Plan (AMP) adds another layer of uncertainty due its lack of sideboards and vagueness in how the state would be involved in the decision-making process if the Master Manual were to change.
