Comment Text: I favor Alternative 2 (even though flawed) and here's why: 1. Alternative 2 is best, but needs changes. It provides the best opportunities for recovery of the three species. It provides adaptive management over time. Alternative 2 includes recognition of the importance of connections to floodplains and includes the option of acquiring increased acres for habitat and mitigation. Alternative 2 is the best option to move toward a more natural river which is good for the three targeted species as well as other fish and wildlife species.

Comment Text: Our qualified support of the Preferred Alternative does not extend to the proposed one-time flow test, which would have the same reservoir release criteria as Alternative 6. Therefore, our comments regarding Alternative 6 also apply to the Preferred Alternative. Additionally, we are unable to provide comments on the impacts of the one-time flow event because the Corps did not model or assess the impacts associated with it in the Draft EIS. In fact, page xi of the Executive Summary states that the Corps did not do so "because of uncertainty of the hydrologic conditions present." The State of Missouri asserts that the Corps cannot implement an action on which the agency has not adequately assessed impacts.

Comment Text: The Corps' Preferred Alternative (Alternative 3) appears to result in the least number of impacts to flood control and downstream flow support for commercial navigation and water supply. Therefore, Missouri supports mechanical habitat construction

as identified in the Preferred Alternative, but only if mechanical construction is implemented in a targeted and contextually sensitive manner. The Corps should implement the Preferred Alternative in a manner that would provide both beneficial habitat and improve overall channel flow conveyance. But habitat construction activities must also comply with all applicable state and federal water quality laws and regulations. In addition, the Corps has determined the channel structures from Kansas City downstream to the mouth are degraded and in need of repair. These insufficient structures cause challenges in maintaining the navigation channel. Therefore, it is important that habitat construction activities within this reach are implemented only after these deficient structures are brought up to their original design dimensions.

Comment Text: It is thought by some that if Alternative #3 doesn't do enough for habitat and the pallid sturgeon, it will show-up in the Adaptive Management (AM) process eventually over time. This is probably true, but this is also a poor reason to accept Alternative #3. Here are some reasons: 1) the appearance in the data might take multiple years to become apparent; 2) a new management action as it is now set-up will take years to be implemented, perhaps up to 15 years (by my calculation) to make its way through Level 1, 2, 3 and finally Level 4, implementation; this includes planning an action, testing in the lab and in study reaches, monitoring and data collection, assessments, final reports, and policy decision-making. I question whether the pallid sturgeon has that long! Most of the reproducing wild pallid sturgeon are an aging population and another decade or two will see the last of those individuals. 2) Even if the Adaptive Management Plan shows that the chosen management action is not working, the forward process is fraught with if this and if that conditions which have to be met. Both the AM and EIS seem to be so concerned that one interest group or another will be even minimally impacted, that the processes as written will take years to clear the hurdles; and 3) which brings me to the fact that there are specific interest groups, who are suspicious of the AM, and would likely oppose any findings by the AM which would require changing the status quo. Indeed, as I have stated, I believe it will be difficult for the research and studies of Level 1, 2, and 3 to be implemented because they will always be met with resistance if their results indicate river management (and probably the Master Manual) needs to be changed to help the species. As years go by and staff and program priorities change, there is less and less likelihood that new/reserve hypotheses are pulled down off the shelf and put into Levels 1-4, and that AM will ever be fully applied.

Comment Text: Plans for development of spawning habitat and interception rearing complexes (IRC) for larval pallid sturgeon as outlined in Alternative 3 should be implemented. Expanding the budget for Level 1 and 2 research on the effectiveness of physical habitat creation and modification within the current river channel needs to be a priority. However, if research indicates these habitats are contributing to reproduction and recruitment of pallid sturgeon, we recommend the goal of 20 acres of shallow water habitat or IRC per river mile be increased to 30 acres per river mile, the upper end of the range specified in the 2003 Amended Biological Opinion. An additional justification for an increase in effort on Level 1 and Level 2 studies in the years immediately following plan implementation is the requirement that if Level 1 studies during the first 9-10 years do not provide a clear answer on whether a spawning cue is important, a one-time, bimodal spawning cue test release from Gavins Point Dam, as outlined for Alternative 6, be conducted. South Dakota recommends the research effort be increased such that in 9-10 years, there is sufficient information to determine if flow modifications to annual operations of the system are needed to support pallid sturgeon recovery.

Comment Text: After a thorough review of the six management alternatives presented for consideration, the State of South Dakota supports preferred Alternative 3 (mechanical habitat construction only), with some modifications requested. Alternative 3 differs from Alternatives 4 and 5 in that there is not a spring or fall flow release aimed at creating emergent sand bar habitat (ESH) for piping plover and interior least tern. Spring flow releases to act as pallid sturgeon spawning cues or to aid in pallid sturgeon recruitment are also not included in Alternative 3, as they are for Alternatives 2 and 6. South Dakota supports Alternative 3 with modifications

requested because we agree that there is enough uncertainty in the science related to flow patterns, volumes, and frequency needed to serve as a pallid sturgeon spawning cue or to aid in sturgeon recruitment, that these actions, and their impacts on South Dakota residents and municipalities, cannot be justified at this time. South Dakota supports efforts to recover endangered species, however, potential impacts of management actions that negatively affect basin stakeholders must be carefully considered with the potential benefit to the listed species. At this time, negative impacts of flow modifications are known and potential benefits to pallid sturgeon population status are unknown.

Comment Text: TNC is concerned by the lack of environmental flows contained in the current Preferred Alternative in the draft MRRMP-EIS. The inclusion of an "Experimental Flow Release - if required" in 2025 as identified in the Preferred Alternative is a small step in the right direction, but hardly reflects Fish and Wildlife as an authorized purpose in the operation of the Missouri River mainstem system. TNC has a long history of working on environmental flows and over a decade of it with USACE through the Sustainable Rivers Project. To supplement these comments, we are attaching a 2014 letter and report by the Chief of Engineers Environmental Advisory Board and the 2015 response by the Chief of Engineers. TNC understands the challenges and constraints USACE faces on the Missouri River in terms of implementing environmental flows, but TNC does not believe they are insurmountable and would propose two approaches for inclusion in a MRRMP-EIS preferred alternative: 1. To enhance the research surrounding "Big Question 1: Spawning Cues" TNC recommends inclusion of Level 2 Experimental Flow Decreases from Gavins Point Dam in addition to (not replacing) the proposed release. These decreases would be timed to coincide with high flow events at appropriate water temperatures (spawning) occurring on the tributaries near Gavins Point Dam to attempt to enhance localized temperature and turbidity- known factors impacting pallid spawning behaviors. These managed decreases would appear to be already within the Master Manual, should be complementary to the other authorized purposes given timing with increased tributary inflows, and could benefit the research already identified in the Preferred Alternative. 2. Given long known negative environmental impacts and a recent publication in Bioscience (Kennedy et al. 2016) further documenting them, TNC recommends USACE alter (not eliminate) hydropeaking practices on the Missouri River mainstem system. TNC believes this directly applies to the primary biotic response of food availability in both the upper and lower river pallid sturgeon exogenously-feeding larvae conceptual ecological models. And the ecological response of area of suitable foraging habitat in the piping plover conceptual ecological models. TNC offers no specific flow prescription at this time, only that USACE begin evaluating and implementing low stable flows during known periods of peak aquatic-insect laying. TNC believes this can and should be done in ways that minimally affect hydroelectricity

generation while still obtaining the goal of improving aquatic-insect egg laying and rearing. TNC also believes evaluation of the impacts on these same insects by "harassment flows" to discourage bird nesting a low sandbar elevations should be considered. TNC believes these minor water management adjustments could bring important ecological and informational benefits, be acceptable to a broad range of stakeholders, and thus, make important additions to the MRRMP- EIS preferred alternative. TNC also wants to emphasize it recommends these adjustments because it trusts USACE to implement these water operations safely.

Comment Text: The selected alternative management actions described in sect 5.3 are entirely insufficient to avoiding jeopardy for the pallid sturgeon, and mostly insufficient for the terns and plovers. It is difficult to conceive how a reasonable mind could read the details found in the effects analysis and integrated report for the pallid sturgeon, conduct the analysis described in this DEIS, and yet,, and yet, STILL, arrive at Alternative 3 as suggested preferred, much less, the selected alternative. If the Corps is to construct an entire programmatic EIS for the purpose of 'avoiding jeopardy' then the end product MUST avoid jeopardy, and- - by preferring Alt 3, and for other reasons- - this DEIS does NOT avoid jeopardy. It creates jeopardy, even after considering and describing many- - though, not all- - of the things it should do to avoid jeopardy.

Comment Text: It is extremely unlikely that Big Questions 1 through 4 (SAMP-draft 6- Sect 4.2.4, table 43; and elsewhere) which refer to, and study, "naturalized flows" can be efficiently or definitively answered by passively monitoring existing, or historical record, Corps operated flows. Of the five hypotheses deemed, by the Corps, to meet or exceed criteria stipulated by the Effects Analysis documents for "avoiding jeopardy", only Alternative 2 aims at approximating "naturalized flows". Alternatives 4 through 6 aim at remediating interventions for the attenuation of naturally occurring flow regimes; but these interventions for attenuations caused by the dams, reservoirs and BSNP channelization are not, in and of themselves, natural. Moreover, even as some of the corollary hypotheses already benefit from Level 1 reflection on past operations data, these hypotheses become bootless and cannot be tested by falsification if they cannot ascend the stepwise decision process through levels 2, 3 and 4- - which is the implicit effect, if Alternative 3 is retained as preferred to become the selected alternative. Level 2 lab studies would have no effect on pallid sturgeons

living in the river and insufficient statistical power to overcome what is, essentially, a policy decision preference for an intervention (Alt 3) that may not work.

Correspondence Id: 224 **Comment Id:** 644409 **Coder Name:** jgutierrez

Comment Text: In spite of concurrence that Alternative 3 represents the best presented option, the State is concerned that in the process of constructing many of the Shallow Water Habitat practices, sediment is routinely removed from parts of the river and adjacent banks only to be placed back in the main channel of the river where it is flushed downstream. This practice is counterproductive to the goals of both the Iowa Nutrient Reduction Strategy and the Mississippi River/Gulf of Mexico Hypoxia Task Force, which call for significant reductions in the transport of nitrogen and phosphorus to the Gulf from our state. We believe that state and federal agencies should be held to the same standards as our agricultural and urban constituents with respect to reducing nutrient transport by way of our rivers and streams, and that the practice of placing nutrient-laden sediment into the river channel will only add to the challenge of improving water quality in Iowa and downstream. To that end, we request that any mechanical habitat construction be undertaken in a manner that avoids, to the greatest extent possible, deposition of sediment back into the Missouri River.

Organization: State of Iowa

Comment Text: The Missouri River is an important resource for both the citizens of Iowa, and for the wildlife that depends on it. While supportive of all eight authorized purposes, the State has a prioritized interest in flood risk reduction and efforts that are aligned with the State's Nutrient Reduction Strategy. Habitat mitigation efforts were intended to benefit a wide variety of species by providing natural areas, but they also play a role in flood risk reduction and nutrient reduction strategies (water quality). Over the past decade, there have been several Missouri River flood events on the lower river which have repeatedly caused extensive flood damage to private lands and infrastructure in Iowa. The existence of mitigation acres within the floodplain reduces flood damage costs and reduces nutrient transport. It appears that most of the focus of the Preferred Alternative is the construction of interception and rearing complexes and spawning habitat primarily in the state of Missouri. While these relatively new habitat types may be of particular importance to the Pallid Sturgeon, we believe other traditional shallow water habitat construction projects (bank notches, dike notches, revetment notches, placement of new structures, side channels, chutes, and channel widening/top-width widening) should continue to be considered throughout the lower river because of their demonstrated effectiveness in providing multiple species benefits, along with flood control and water quality improvements.

Correspondence Id: 183 **Comment Id:** 643928 **Coder Name:** jgutierrez

Comment Text: The USFWS will not complete a final assessment of the ability of the Draft MRRMP/EIS to achieve its purpose and objectives until consultation pursuant to section 7 of the ESA (Section 7) are complete. However, at this time the USFWS is concerned that the suite of actions in the preferred alternative alone may not meet the purpose and objectives of the Draft MRRMP/EIS. The near-complete reliance upon mechanical construction in the Missouri River system overlooks the value of ecological functions to support the program purposes. Restoring natural flows should be a cornerstone of management approaches to river ecosystems (Poff et al. 1997), yet the current Draft MRRMP/EIS preferred alternative only includes them as a potential for testing the applicability of flows. The 2003 amended biological opinion reinforced the importance of a more natural flow regime linked with physical habitat improvements: Continued survival of pallid sturgeon depends on restoration of riverine form and functions, as well as some semblance of the pre-development or natural hydrograph. Missouri River habitat restoration is, therefore, multi-faceted, and involves a combination of reservoir operational changes (e.g., hydrograph and temperature), structural modifications (e.g., chute restoration), and non-structural actions (e.g., floodplain acquisition or easements). The maximum benefits of physical habitat projects to listed species can only be realized when coupled with complementary hydrology.

Comment Text: Similarly, Alternative 3 identifies only 12 pallid sturgeon early life stage habitat areas. This is insufficient to expect success. If we confine those only to the lower channelized reach that represents one site each 61 miles. To be successful, habitat for early life stages of pallid sturgeon must be at both reasonable distances (and suitable locations) throughout the system. It is important to keep in mind that a larval fish has limited mobility and ability to find and access preferred habitat in this high velocity modified system. It is also important to note that discussion of these areas also seem to plan for these areas to be concentrated very low in the system. Drift, whether it is of larval fish, benthic invertebrates or detritus in the system is a non-uniform event. Drift of these organisms cannot be expected to behave as a model of water flowing downstream. Even in a highly modified channel "roughness" of the channel will create variation in drift rates from varying velocities, eddys, areas behind dikes, etc. Suitable rearing habitat must be created at various locations throughout the system.

TNC offers no specific flow prescription at this time, only that USACE begin evaluating and implementing low stable flows during known periods of peak aquatic-insect laying. TNC believes this can and should be done in ways that minimally affect hydroelectricity

generation while still obtaining the goal of improving aquatic-insect egg laying and rearing. TNC also believes evaluation of the impacts on these same insects by harassment flows to discourage bird nesting at low sandbar elevations should be considered. TNC believes these minor water management adjustments could bring important ecological and informational benefits, be acceptable to a broad range of stakeholders, and thus, make important additions to the MRRMP- EIS preferred alternative. TNC also wants to emphasize it recommends these adjustments because it trusts USACE to implement these water operations safely.

Comment Text: Mid-West supports a slightly revised Corps Preferred Alternative. The one revision to the Preferred Alternative Mid-West proposes is the addition of more off-channel, non-ESH work for plovers. As the work highlighted in the recent MRRIC Annual Forum (Michael Anteau, U.S.G.S., Conservation of Piping Plovers on the Missouri River: Thinking Beyond the Banks) suggests, there are productive habitat opportunities beyond the banks of the Missouri River that could prove very useful to piping plover recovery. With the addition described above, Mid-West supports the Preferred Alternative for the following reasons. First, it provides the best balance of actions likely to result in recovery of the ESA-listed species versus the environmental and economic consequences of those actions. Second, it has the smallest environmental consequences of all the other alternatives in virtually every category, including the No Action alternative. Finally, the Preferred Alternative's embrace of Adaptive Management is entirely appropriate given the magnitude of the scientific uncertainty surrounding all three of the ESA-listed species. For these reasons, Mid-West believes the Preferred Alternative is the superior alternative for ESA-listed species recovery on the Missouri River.

Comment Text: We believe Alternative 3 comes the closest to striking a better balance than the other DEIS alternatives in protecting human interests and promoting species recovery. We do appreciate the Corps's cancellation of the current bimodal spring rise as outlined in this alternative, but remain fully concerned that a spring rise could be considered further down the line in this alternative. Until the Corps or the Services can produce peer reviewed science that supports a spring rise as an effective tool to pallid sturgeon recovery, the rise shouldn't even be part of the conversation of river management.

Comment Text: Of the six alternatives presented in the EIS, we concur with the Corps assessment for the preferred Alternative 3 - Mechanical Construction Only. We believe it best balances effective measures to address the jeopardy of the three species while collectively minimizing the costs and impacts to human considerations. As noted below, we remain skeptical of the value of, and concerned with the potential risk posed by, the one-time spawning cue test included in Alternative 3. By contrast, none of the other alternatives are acceptable to Ameren as they threaten to diminish Missouri River flows at vital facilities and at critical times. Alternative 3 promises both economic and operational benefits compared to other options. Impacts on Thermal Power plants were assessed based on the Corps evaluation of twenty one facilities. Based on the Corps modelling, the National Economic Development impacts for the affected power generating facilities are reduced (annually) under Alternative 3 by an estimated \$1.4 million over the No Action alternative. Others by contrast, such as Alternative 2 are estimated to cost over \$28 million more (annually).

Comment Text: The US Army Corps has recommended Alternative 3 labeled as Mechanical Construction Only. This alternative does not do enough to conserve and protect the natural resources of the Missouri River such as the prey base for pallid sturgeon. We agree that large scale experimentation as proposed by level-2 experiments would be beneficial, but the scope of such experiments seem extremely limited to just flow pulses. A one-time flow pulse does not constitute a natural flow regime. Establishing a more natural flow regime in combination with habitat construction through an adaptive management plan is a more prudent approach which tries to work with mother nature.

Correspondence Id: 103 **Comment Id:** 636883 **Coder Name:** jgutierrez

Comment Text: Concern The Conservation District stakeholder group cannot support limiting the MRRMP and DEIS's preferred alternative recommendation to the Alternative 3 - Mechanical Construction Only option for recovering the Missouri River's threatened and endangered species as stated in Vol. 1, Executive Summary, page xxviii. Basis for the Concern As a result of our working with these natural resources for many years, we believe the Mechanical Construction Only alternative will not facilitate the reestablishment of most of the inner acting components that are needed to fully recover the Pallid Sturgeon, Piping Plover and Least Tern species and avoid jeopardizing or endangering other species that rely on the river for their needed habitat. Significance of the Concern By limiting our recovery actions to Mechanical Construction Only, we are not going to be able to rehabilitate the river's eco-system back to its pre-construction condition. We need to include the management practices that are included in Alternatives 4, 5, and 6 that will help mimic the pre-construction natural flows and habitat as best we can. Not only is Alternative 3 inadequate in repairing the natural eco-system, we believe it is not financially sustainable, either. As good stewards of our natural resources, we have to learn how to work in harmony with these natural resources as God created them and not as how man thinks they need to be manipulated.

Comment Text: Thus far, though, we have concerns on the Corps' preferred Alternative No. 3. This one utilizes mechanical construction to create shallow water habitat, interception rearing complexes and emergent sandbar habitat. Our concerns primarily focus on future funding for recovery efforts that are outlined in Alternative 3. We ask what happens if funding for mechanical construction is not available or zeroed out by Congress. This has happened with other Missouri River efforts and programs in the past. Is there a Plan B contained in Alternative 3? If so, we haven't seen it in the DEIS.

Organization: Izaak Walton League of America (South Dakota, Nebraska, Iowa)

Commenter: Paul Lepisto **Page:** **Paragraph:**

Kept Private: No

Correspondence Id: 50 **Comment Id:** 628615 **Coder Name:** jgutierrez

Comment Text: First, I want to talk about Alternative No. 3. It is an all mechanical alternative, which means bulldozers and that type of thing will push sand around, and it is essentially the least sustainable and the worst alternative. It has received a great deal of support by all the people who do not want flows in the river, who don't want to see anything change, and you have heard that tonight. So instead of using flows on the river to produce sandbars, it'll be artificially done. The pallid sturgeon, the third of the three species, will have little benefit to be gained from this alternative, although they are creating what they call the IRCs, the interception - - oh, what is the - - rearing complexes. And this is done on two wing dikes a year and over a span of about ten years, which is really, on the lower river, far too few and far too long of a time period.

Correspondence Id: 223 **Comment Id:** 644938 **Coder Name:** jgutierrez

Comment Text: It is not until later in the MRRMP-EIS, shrouded within the lengthy alternatives analysis itself, that the selection of Alternative 3 is justified because it "has a wide range of benefits relative to Alternative 1, including certain benefits to endangered species, reduced program expenditures, and increased performance for most HCs." The MRRMP-EIS even states that Alternative 3 can be selected although it is less likely to meet species goals than Alternative 2: Although there are uncertainties associated with its effectiveness in meeting the species objectives (in common with Alternative 4, 5, and 6), Alternative 3 clearly demonstrates it would be the least impactful means of potentially meeting species objectives across the full range of interests. [Emphasis added] This statement begs several questions. Why would alternatives be proposed which contain appreciable "uncertainties associated with [their] effectiveness in meeting" species goals? Why does the chart provided in the Executive Summary distinguish effectiveness only by using the word "Exceeds" for Alternative 2's piping plover and interior least tern objectives? Why is the preferred alternative the one that potentially meets species objectives when the entire purpose of the MRRMP-EIS is to avoid jeopardy?

Comment Text: As summarized in the Hydropower Environmental Consequences Analysis Technical Report, Alternative 3 provides the best economic impact result for hydropower generators. Iowa's consumer-owned electric utilities include rural electric cooperatives (REC's) and municipal utilities. These Iowa based utilities, along with approximately 300 other consumer-owned utilities in the Missouri River Basin, also have a critical dependence on the Missouri River. The Western Area Power Administration (WAPA) supplies them with electric power generated by six hydroelectric facilities located on the river. Changes in Missouri River operations can affect Iowa consumer-owned utilities that purchase power from WAPA. When WAPA cannot generate enough hydroelectric power to fulfill its contractually obligated agreements due to low water, WAPA must go to the open market and purchase electricity, often at higher costs, which are passed on directly to the consumer-owned utilities that receive electricity from WAPA.

Comment Text: The following comments are Montana-Dakota's evaluation of the proposed alternatives and may change depending upon the USACE's further evaluation of issues and implementation of recommendations Montana-Dakota provided above. If no changes to the overall results occur after consideration of our recommendations, we believe that the Alternative 3 (identified as the preferred alternative in this MRRMP-EIS) would be the least disruptive Alternative to Heskett's current operation and is preferred. Alternative 3 is described as: 2.9.2.3 Alternative 3 - Mechanical Construction Only Summary of Characteristics and Features.

Hydrologically, the effects of this alternative would be very close to those for Alternative 1 but without the specification for spawning cue releases in March and May. Hydrological differences would be reduced flows relative to Alternative 1 in approximately 30 to 50 percent of years in late March and late April/early May, and corresponding increased flows relative to Alternative 1 during one or two weeks in October or November. The differences in magnitude of these flows would be small compared to those associated with the other alternatives. Alternative 3 would have less channel reconfiguration for pallid sturgeon early life stage habitat relative to Alternative 1, and this would have implications on flow routing and assumed stage- discharge relationships at certain locations. Therefore, Alternative 3 has been identified as the preferred alternative in this MRRMP-EIS.

Comment Text: Specifically it appears that Alternative 3 operates inside the current Master Manual. We see this as very positive. In addition, Alternative 3 provides more available storage for low flow periods allowing municipalities to better manage service. Alternative 3 provides several hundred more acres of Emergent Sandbar Habitat through mechanical construction. This should provide sufficient habitat to alleviate the need for releases from the Kansas Reservoirs to protect the limited habitat create by other alternatives. The State of Kansas has long opposed the use of Kansas River reservoirs for flow support on the Missouri River when the other tributary reservoirs in the system are left untouched. This practice represents an unbalanced threat to Kansas water supplies during the uncertainty of drought and impacts our local economies. Finally, Alternative 3 also has the least National Economic Development (NED) impact and appears to be a good balance between overall efficiency and impact to certain NED resources.

Comment Text: With the addition described above, CMEPC supports the Preferred Alternative for the following reasons. First, it provides the best balance of actions likely to result in recovery of the ESA-listed species versus the environmental and economic consequences of those actions. Second, it has the smallest environmental consequences of all the other alternatives in virtually every category, including the No Action alternative. Finally, the Preferred Alternatives embrace of Adaptive Management is entirely appropriate given the magnitude of the scientific uncertainty surrounding all three of the ESA-listed species. For these reasons, CMEPC believes the Preferred Alternative is the superior alternative for ESA-listed species recovery on the Missouri River.

Comment Text: Alternative 4 - The League is concerned with this alternative's focus on how far to draw down water stored in the reservoirs. Lack of water in the system impacts seven of the eight authorized purposes. We also have concern over the potential long refill time for reservoirs after the planned large release. The DEIS states that refill time for the reservoirs could take "months to years." Additionally, the second planned release outlined in the alternative may begin before the reservoirs can refill, drawing them down to even lower elevations. We believe most of the impacts from this alternative would be negative. For example, the DEIS says the levels on Lake Oahe and Lake Sakakawea could drop by as much as 5 feet. This would impact many of the authorized purposes. We feel the benefits this alternative provides do not outweigh its many negative impacts.

Correspondence Id: 223 **Comment Id:** 644951 **Coder Name:** jgutierrez

Comment Text: The spring and fall flow releases found in Alternatives 4 and 5 do not represent a meaningful difference because their effects are virtually indistinguishable. Nor do the flow releases distinguish Alternatives 4 and 5 from Alternative 3 because they will take place too infrequently to matter. Although the flow releases are intended to "create ESH for the least tern and the piping plover," the MRRMP-EIS at no point discusses the amount of ESH that would result, stating simply that the flow releases will "be adjusted to respond to hydrologic conditions at the time."⁸⁵ Practically speaking, the years that the flow releases will not occur are far more frequent than the years in which they will occur partially or to completion. In terms of the modeling for Alternative 4, the MRRMP-EIS indicates that during the 82-year period of record (POR), "the spring habitat-creating flow release as defined here would have been implemented 10 times and would have been partially implemented 7 times."⁸⁶ This means that the flow release is only fully implemented 12.2% of the 82-year POR. The modeling for Alternative 5 indicates that during the 82-year POR, "the fall habitat-creating flow release as defined here would have been implemented 7 times and would have been partially implemented 2 times."⁸⁷ This means that the flow release is only fully implemented 8.54% of the 82-year POR. The infrequency of the habitat creating flow release raises doubt that the ESH goals of the 2003 Bi Op will be met through utilization of flow releases. The infrequency of the flow releases and the unlikelihood that the ESH goals of the 2003 Bi Op will be met show that Alternatives 4 and 5 are neither meaningfully different from, nor more effective than, Alternative 3.

Comment Text: Alternative 4 would be the most disruptive to Heskett's operations and we firmly oppose this alternative. This alternative also appears to favor downstream interests while penalizing upstream sources. Underlined portions of the report summary describing this inequity are as follows: Alternative 4 would result in benefits to power generation and energy values in the lower river and adverse impacts to power generation and energy values in the upper river when compared to No Action, with negligible changes on average across all locations. The benefits in the lower river would occur from slightly lower summer river temperatures from the construction of fewer acres of early life stage habitat for the pallid sturgeon. Adverse impacts to power generation and energy values in the upper river would be temporary and range from small to large, stemming from relatively lower river flows in the fall while reservoirs rebalance following a spring release. There would be negligible impacts to variable costs and capacity values compared to No Action. RED impacts to household and business spending and associated regional economic conditions as a result of changes to consumer electricity rates would be the same as those described under No Action because reductions in power generation under Alternative 4 in the upper river would not occur during peak periods. The OSE impacts would be the same as described under No Action. Alternative 4 would result in uncertain effects on air quality because many of the affected plants are coal-fired plants and the fuel types for the replacement source include fossil fuels. Alternative 4 is not anticipated to have potential significant impacts on thermal power because adverse impacts to power generation to power plants in the upper river would occur during offpeak seasons and there would be beneficial impacts to power plants in the lower river. Montana-Dakota agrees that Alternative 4 is not the preferred alternative and appreciates that the USACE has made this distinction and has not chosen to implement this alternative.

Comment Text: Recommended Actions to Resolve We believe that Alternatives 3, 4, 5, and 6 all need to be considered viable options to use in this recovery effort. As stated by Mark Harberg in his MRRMP-EIS Public Meeting presentations, current science validates the river's eco-system needs a much broader and dynamic management plan than a mechanical construction only option. By including Alternatives 4, 5, and 6, when the conditions are right and needed, we will be able to work more harmoniously with the elements of this eco-system to recreate the needed habitat and food for all the species in the basin.

Comment Text: Removing the Intake dam near /Glendive seems like an issue that would relate to only a few hundred people in that area. The authorized purposes study would reveal that the people who would be affected who irrigate almost 58,000 acres would have to change, but not profoundly. There are only a few people near Glendive who really make a livelihood from irrigating crops. There could be sufficient federal funding that the citizens of the area might feel they had won the lottery.

Comment Text: Lowering pools, on average- -the March 1 target- -is practically a taboo idea in the MR basin, even in the wake of the truly frightening flood of 2011. I believe that lower pools will give you more flexibility in storage and releases that will permit real rsrv unbalancing in more years. Lower pools also have the crucial advantage of reducing the need for high summer flood-control releases that have too often flooded tern and plover nests on sandbars below the dams. Lower pools also produce lower river flood damage reductions, and I hope you will consider an alternative that incorporates a lower storage target and navigation service levels, better unbalancing, and overall better management of pools for terns and plovers and other wildlife benefits. The Corps manages hundreds of miles of reservoir shoreline via water levels, and it's a shame to be overlooking opportunities for creative habitat enhancements over that long shoreline.

Comment Text: In Section 2.5.3.1, it states that channel reconfiguration is a management action considered with multiple types of practices that could be implemented (e.g., bank notches, dike notches, revetment notches, placement of new structures, side channels, chutes, and channel widening/top-width widening). In the Upper Mississippi River Habitat Rehabilitation Program (HREP), they have successfully conducted multiple large scale projects that include the creation of islands, backwater areas, etc. and return the river to a more natural state. We believe these much larger scale practices should be considered in the Missouri River in the future so meaningful restoration can be accomplished. There is also evidence to support that young-of-year Scaphirhynchus spp., Paddlefish, and Channel Catfish utilize these large scale island habitats in the Middle Mississippi River (Phelps et al; 2009; Phelps et al. 2010; Phelps et al. 2011, Love et al. 2016). Larger projects such as those completed in the Upper Mississippi River that includes numerous varieties of habitats may be more likely to support multiple life stages of Sturgeon spp. These large scale habitat improvements are also likely to benefit other fish species, least turns (nesting site documented on Deer Island top widening project), piping plovers, waterfowl, invertebrates, vegetation, and recreation that smaller scale projects (e.g., dike notches, revetment notches, etc.) will not likely be able to provide. Connecting multiple habitat complexes together may be beneficial as well to help reduce fragmentation and increase the chances of young of year fishes to utilize these resources. Large scale habitat rehabilitation projects that include a variety of habitats will not only provide benefits to fish and wildlife, but could also create habitats in the floodplain (e.g., emergent wetlands, woodlands, grasslands, etc.) and backwater areas. These new variety of floodplain habitats would increase the hydraulic capacity of the river and associated floodplain, as well as reduce the amount of nutrients entering the river through the uptake of terrestrial and aquatic vegetation that could be created. The preferred alternative 3 consists of constructing interception and rearing complexes, largely through small scale projects (e.g., dyke notching, top widening, etc.) in the state of Missouri. Projects that include structure modifications and channel widening projects, while a step in the right direction, are largely small scale projects that have not, and will not likely reach anticipated results. We believe the Upper Mississippi River HREP program could be used as a good example of all agencies and stakeholders working together to make an ecologically relevant difference while meeting all needs and authorized purposes.

Comment Text: As Missouri citizens, we know that our state has far more people and infrastructure at risk from flooding and also more risks to drinking water supplies and to navigation on the Mississippi River below the confluence from low flows than any other state in the basin. We acknowledge the constraints under which the Corps must operate to reduce these risks. We would point out, however, that these risks have been heightened by the Corps' construction and maintenance of the Bank Stabilization and Navigation

Project and failure to enforce the 3,000 to 5,000-foot-wide floodway mandated in the 1944 Flood Control Act. Hence we believe the Corps must pursue every opportunity to acquire available lands in the floodway and to remove or set back the levees in order to reduce flood risks.

Correspondence Id: 237 **Comment Id:** 643110 **Coder Name:** jgutierrez

Comment Text: While this plan is looking specifically at avoiding jeopardy for Pallid Sturgeon, the Nebraska Game and Parks Commission believes that a systematic plan of top-width widening for the entire channelized reach in Nebraska would provide huge positive economic benefits to the Missouri River system not considered in any of the alternatives presented. The 2011 flood on the Missouri River resulted in an estimated \$2 Billion dollars in damage (Dept. of Commerce, 2012), much of that occurred along the Nebraska reach of the river, while the U.S. Army Corp of Engineers spent over \$500 Million to repair flood control works in the Missouri River Basin (Blechinger, comments to MRRIC, 2012). The 2011 flood was the result of decisions made in the name of navigation that has resulted in a Missouri River channel in Nebraska that lacks channel capacity and has intentionally eliminated the habitat diversity that is necessary to support Pallid Sturgeon and the ecosystem upon which they depend. The 2011 event should not have resulted in a flood, it was simply the channel capacity in the upper channelized river below Sioux City which was engineered out of the system to provide a 9 foot deep self-scouring channel to support a navigation industry that has not substantially developed. With the capacities of the large main stem and tributary reservoir system in the basin that have subsequently developed, a systematic widening of the channelized Missouri River in Nebraska would substantially decrease, if not eliminated, the impacts of another 2011

event. If \$2.5 Billion would or could be spent on increasing channel capacity and habitat diversity and availability, both the citizens of the basin as well as Pallid Sturgeon and the Missouri River Ecosystem would benefit.

Comment Text: The USFWS believes there is high uncertainty that the least tern, piping plover and pallid sturgeon objectives could be met if there are continued delays to implementing flows during critical life history phases for these species. The USFWS recommends the Corps commit to use other tools such as flows to meet the objectives. We recognize that it may take many years to clear the impediments to use flows to restore the ecological function of the Missouri River. However, incorporating and using the authorities of the Bank Stabilization and Navigation Fish and Wildlife Mitigation Project (BSNFWMP), will benefit both listed and non-listed species, provide increased conveyance and capacity for flood waters, and reduce flood risk to residents, property and infrastructure along the Missouri River. The Corps should focus initial efforts in reaches where flood risk is the highest such as the reach below Fort Randall Dam and other previously identified reaches where pinch points and low-lying land are at risk. Efforts such as this would highlight the Corps commitment to action and ultimately achieving the purpose and objectives of the Draft MRRMP/EIS.

Comment Text: There is no dispute by any science body, the Corps, FWS or any State conservation authority that the lower Missouri River is sediment starved. In 2010, the National Academy of Science conducted a review at the Corps' expense and verified the conclusion. The dredging EIS reached the same conclusion in 2011. The FWS took specific positions arguing that the pallid needed greater load to be successful in the NSF hearings. Ironically, after all the determinations that the river is sediment starved, the issue has disappeared. We have spent years challenging the fact that the mainstem reservoirs create the sediment problem and force the river's reliance on tributary load to recover bed conditions and restore historical load factors. Reservoirs in the system are filling with material. Yet the management plan perpetuates the fiction that riverine habitat must only be adjusted by flow without reintroduction of material from behind the mainstem dams. Currently, when an action is taken, load is created by compromising channel characteristics (notching and shallow water habitat) versus enhancing natural load and turbidity by allowing material to be moved from behind mainstem dams. None of the alternatives, including the preferred alternative, address the sediment starved river due to retention behind the mainstem dams, the spawning affects related to that trapped material, and the impact on the species.

Comment Text: We recognize that land acquisition for mitigation purposes is an imposition on landholders in the floodplain. We do not agree with the position of the Corps focusing on high dollar lands to "double dip" to meet their mitigation requirement and their ESA responsibilities. The Corp is required to purchase 167,000 acres to mitigate for the imposition of the BSNP. They have acquired approximately 60,000 acres to meet that objective. There are two distinct issues regarding land acquisition - mitigation and ESA. Mitigation does not require premium landholdings with direct connectivity to the river. We encourage the Corp to continue to meet the mitigation objectives from willing sellers by purchasing less costly land holdings worthy of habitat substitution for ALL species - not just those endangered.

Comment Text: 2. The differences in spawning habitat construction are unreasonable. In addition to the substantial differences in the amount of ESH construction between Alternative 2 and Alternatives 3 through 6, the differences in spawning habitat construction, a management action intended to avoid jeopardy to the pallid sturgeon, are significant and unexplained. Spawning habitat construction is not included as a management action in Alternative 2 but is included in Alternatives 3 through 6. Spawning habitat construction calls for the Corps to "construct up to three high-quality spawning habitat sites"⁵⁶ which would be continually monitored for "the relative spawning success, as determined by hatch rate, catch per unit effort of free embryos, and other indicators."⁵⁷ In theory, the use of spawning habitat sites would help protect the pallid sturgeon, but "sufficient understanding to characterize the necessary features of high quality pallid sturgeon spawning habitat does not exist."⁵⁸ Even though "sites would be constructed following initial studies to further clarify habitat specifications," there is a possibility that the sites would not provide any significant benefits to the pallid sturgeon spawning season or overall population. ⁵⁹ Spawning habitat construction would be time-consuming due to waiting on initial studies to be concluded before commencing construction. It would also be expensive with a total cost of \$1,109,735 and an annual cost of \$123,304. Given the uncertainty surrounding spawning habitat construction, these funds could be put to better use on management actions that have proven benefits to the pallid sturgeon, such as early life stage habitat construction. The use or nonuse of spawning habitat construction is a substantial difference between Alternative 2 and Alternatives 3 through 6 because Alternative 2 does not incorporate this management action at all. There are other options that are available and reasonable other than simply excluding or including the creation of spawning habitat. Since spawning habitat creation has not been sufficiently studied, it is reasonable to consider an alternative in which proactive AM, including Level 1 and 2 studies, is first used to assess the specifications of spawning habitat construction and to determine whether the action would have positive impacts on the pallid sturgeon. An alternative using a middle-ground approach to spawning habitat construction would potentially be more effective than either including or excluding spawning habitat construction.

Comment Text: Along with these differences in the management actions of Alternative 2 and Alternatives 3 through 6, there is a huge cost difference between the alternatives, which leaves room for middle ground alternatives. Table 4 below shows some of the total costs associated with early life stage habitat construction for each alternative: [Table 4: Total Costs of Early Life Stage Habitat Construction Per Alternative] In every category, Alternative 2 is much more expensive than Alternatives 3 through 6. Alternative 2 has much greater costs than the No Action Alternative with differences ranging from about 60 to 150 percent whereas Alternatives 3 through 6 save much more than the No Action Alternative with differences ranging from about -30 to -120 percent. There is clearly

room for additional reasonable and feasible alternatives to create early life stage habitat with costs that fall between the ranges of Alternative 2 and Alternatives 3 through 6.

Comment Text: Alternative 6's recurring spawning-cue flow release likewise differs only slightly from Alternatives 3 through 5. 88 Alternatives 3 through 5 contain a one-time spawning cue flow, which is replaced by the recurring release in Alternative 6. The recurring release requires the Corps to "attempt a spawning cue release every 3 years consisting of a bimodal pulse in March and May."89 However, just as with the flow releases in Alternatives 4 and 5, the spawning-cue release will "be adjusted to respond to hydrologic conditions at the time."90 The model for Alternative 6 "indicates that over the 82-year POR, the spawning-cue release as defined here would have been implemented 11 times and would have been partially implemented 33 times."91 This means that the spawning cue release is only fully implemented 13.4% of the 82-year POR. As in Alternatives 4 and 5, the lack of frequent implementation in Alternative 6 shows that there is no evidence that the spawning cue release would have significant positive impacts on pallid sturgeon goals. In addition, the spawning-cue release has not yet been proven to be effective to the spawning patterns of the pallid sturgeon: "the exact characteristics of a spawning cue pulse that would elicit a spawning response are not known. The Independent Science Advisory Panel (ISAP) found no evidence that managed spring pulses are necessary to provide cues for pallid sturgeon spawning."92 Just as the infrequency of the flow releases and the unlikelihood that ESH would be created meant that Alternatives 4 and 5 differed only slightly from Alternative 3, the infrequency of the spawning-cue release and the consequential lack of a positive impact on the species make it very much like Alternative 3. Table 5 below outlines the years of full and partial implementation of flow releases over the 82 year POR for Alternatives 4, 5, and 6 showing the infrequency of the flow releases and ultimately the ineffectiveness of flow releases as a management action: [Table 5: Implementation of Flows in Alternatives 4, 5, and 6] The management actions that supposedly distinguish Alternative 3 from Alternatives 4 through 6 will occur less than 14% of the time over an 82-year period. It is also likely that the management actions will provide little assistance to the species beyond that found in Alternative 3. Furthermore, none of Alternatives 4 through 6 have additional costs associated with them because of their varying flow releases, so they purportedly cost the same as Alternative 3.93 Because Alternatives 3 through 6 are essentially the same, the range of alternatives falls short of meeting the requirements of NEPA.

Comment Text: C. The Corps Should Produce Reasonable and Feasible Alternatives Combining the Best Management Actions Among Alternatives 2 Through 6. Due to the lack of a reasonable range of alternatives in the MRRMP-EIS, and the large differences between Alternatives 2 and 3 through 6, there should be reasonable and feasible alternatives that combine the most cost-effective actions from each. ESH Construction. As described above, Alternative 2 differs from Alternatives 3 through 6 in the amount of ESH construction. The amount of ESH construction proposed in Alternative 2 varies by 88.97% from Alternative 3. 94 In addition, the cost of the proposed ESH construction for Alternative 2 is 91.7% greater than the cost of ESH construction for Alternative 3.95 Both Alternatives 2 and 3 only create ESH through mechanical means and so it makes sense to compare them directly.

Comment Text: Adaptive Management Planning. Spawning habitat construction, spawning cue releases, and IRC for early life stage habitat construction need further study before they can be effectively implemented. The alternatives present two types of iterative actions that could be utilized to study the effectiveness of these management details: proactive AM97 and Level 1 and 2 studies. 98 The Corps endorses both as effective means of understanding how to prevent jeopardy to the species, but neither is included in Alternative 2. The Corps should propose at least one alternative that contains the most effective actions of Alternative 2 but also incorporates proactive AM and Level 1 and Level 2 studies. Such an alternative could be designed to meet the species goals without immediately using spawning cue releases or spawning habitat construction as described in Alternative 2, but could utilize the new AM Plan to implement spawning cue releases and spawning habitat construction if further study finds them to be effective ways of protecting the pallid sturgeon. This alternative could make use of SWH while waiting on completion of the Level 1 and 2 studies for IRC. The immediate implementation of SWH could benefit the species while the IRC could later be implemented more fully if its effectiveness is demonstrated. Alternatives that include a mix of SWH and IRC are viable options because they could provide the most benefit to the species without wasting time and money. Additionally, if the IRC is not found to be effective then there is already some SWH in place to provide benefit to the species.

Comment Text: During the process of developing management alternatives for inclusion in the MRRMP and EIS, sediment transport from above Gavins Point Dam to the Missouri River below the dam was not included in management actions considered for review and comment by MRRIC. Increasing sediment transport downstream from the impounded section of the Missouri River needs to be included in the MRRMP alternatives. It should also be evaluated in the EIS with regards to potential benefits to the listed species and to overall ecosystem health. Some degree of increased downstream sediment transport will be needed to halt the loss of connectivity between the river and its riparian corridor and to provide needed turbidity and sedimentation for recovery of the listed species. The 2011 National Research Council report Missouri River Planning: Recognizing and Incorporating Sediment Management states that the pre-dam annual sediment load at Yankton for the 1940-1952 period was 125 million metric tons, compared to 0.25 million metric tons today. This is over a 99% reduction in sediment input. The Missouri River below Gavins Point Dam is sediment starved and feeding off its bed and banks. It is obvious sediment augmentation of the Missouri River below Gavins Point Dam needs to be pursued as a part of any long-term management plan to allow the recovery and subsequent sustainability of the listed species.

Comment Text: A better range of alternatives needs to be offered - . Alternatives 4, 5, and 6 should have been merged into one single alternative because they are similar in all ways except for the specifics of each of their flows and the limiting conditions. Alternative #4 has a spring release and #5 has a fall release - to occur every four years IF all three stipulated conditions are met, which in reality will likely happen only half the time, at best. They each will also attempt a one time spawning cue release after about ten years! #6 has a spring bimodal spawning cue release every 3 years, if again, all conditions are met. Each of these releases should be revised and

be of some consequence rather than a token gesture towards releases. The restrictions attached to these releases and the time period over which they are to adhere to almost make these alternatives ridiculous from a biological point of view.

Comment Text: Maintaining the reservoirs at lower levels - The reservoirs clearly indicate that one of their main functions is to assist in flood control for the Basin. But what good are they for flood control if they are always kept full, for the purpose of having sufficient water for releases for navigation throughout the navigation season and to have full reservoirs for the local fishing industry. For true flood control, reservoirs should be kept at 46.8 maf on March 1st, 10 maf lower than the current level maintained. Lower pools augment benefits for the listed birds.

Comment Text: Require barges which operate on the Missouri River be of the shallow draft type - This would allow for more habitat construction and shallower water in the channel for spawning habitat construction. Also more river water could be used to widen the river in coordination with top widening modifications to banks, be used to fill backwaters, and to have greater connectivity to the

flood plain. The Missouri River is not locks and dams, and does not have the deep pools associated with that system. It makes sense that barges that operate on the river should require less draft and at the same time, makes channel habitat construction more possible.

Comment Text: The preferred alternative would benefit from additional measures, some of which are described in more detail below. -Habitat: Creation of IRC or other hydraulic roughness in the Upper Missouri section. The preferred alternative includes the creation of IRC habitat in the lower Missouri River. However, the scientific studies on the Yellowstone and Upper Missouri River indicate that drift distance is insufficient to support survival of young pallid sturgeon. The EIS could consider additional steps to improve anoxic conditions at reservoir arms which also tend to serve as nursery habitat. -Modifications at Fort Peck could be put in place to support flows, warmer temperatures, and hydraulic roughness.

Comment Text: Until the Corps can provide a level of accountability necessary to provide reasonable assurance to the public, none of the alternatives should be implemented. Given that the Corps has not implemented these flow-based RP As for more than a decade, the Corps should identify what checks and balances are in place to ensure these requirements will be implemented. The Corps could implement a good faith reallocation of reservoir uses to better serve the needs of endangered fish and native warm water fish. This recommendation may be the most needed action to ensure the Corps will fully implement any alternative selected, and not just some portions. Examples of how this could be accomplished are discussed briefly below: -Reservoir Reallocation is needed to support implementation Although there appear to be vast amounts of water available in the basin, significant water deficits continue to occur: "Shifting population concentrations, and increasing numbers of industrial and agricultural developments across the state have resulted in a situation where North Dakota's ground and surface water resources are becoming more fully appropriated. Thus, the presence or absence of water has become one of the primary factors in locating industrial plants, or any other developments requiring large amounts of water." 25 Per the Water Supply Act of 1958, storage in Army Corps reservoirs may be reallocated, or new storage may be added, for municipal and industrial (M&I) water supply. The Corp Chief's approval authority for reallocations is limited to 50,000 AF or 15% of the total usable storage, whichever is less. Otherwise, the Assistant Secretary of the Army must approve the plan. Reallocation may occur under one or more conditions: 1) Temporary use of storage allocated for future conservation purposes and sediment; 2) Storage made available by change in conservation demand or purpose; 3) Seasonal use of flood control space during dry seasons; 4) Reallocation of flood control space; 5) Modification of reservoir water control plan and method of regulation; 6) Raising existing dams; 7) System regulation of Corps and Non-Corps reservoirs; 8) Use of water supply storage not under contract. Lastly, a basin wide approach could be taken to regulate flows throughout the basin.²⁶ A number of these options could be used to enhance fisheries populations in Missouri River reservoirs. Additional space is available for reallocation to support pallid sturgeon. The Corps notes that sedimentation has not occurred at the rate expected in the reservoirs,²⁷ and additional water is available from an under-utilized Bureau of Reclamation water right allocated to irrigation. These allocations could be immediately used to develop an

effective plan to enhance and conserve native riverine and reservoir fisheries in the region. Though only seven dams are controlled by the Corps, another 70 exist in the basin, many owned by the Bureau of Reclamation. Managing this system holistically would be beneficial to fisheries. An effective reallocation plan should include the cumulative impact of any reallocation, an assessment of the current status of the authorized uses, and an indication of whether they are currently being met. Flows for downstream fisheries, particularly for the pallid sturgeon, have not been implemented as required by the 2000/2003 Biological Opinion, and full navigation downstream has not been met in the past 13 years. If surplus water is available, it could be reallocated to fish and wildlife and recreation, as these are the most important uses in the Upper Missouri (instead of transportation in the Middle Missouri). Without reallocation of reservoir storage, successful implementation of flow modifications under the alternatives outlined in the EIS are unlikely to occur.

Comment Text: Additionally, the EIS states the importance of sediment in the health of native fish species in the river. Riverine fish species in the Missouri River are adapted to warm, turbid waters. Any adjustments to Fort Peck should also include considerations for life cycle needs and turbidity. The EIS notes that sediment, turbidity, and phosphorus concentrations downstream from Fort Peck Dam are much lower than upstream concentrations. The natural level of turbidity does not recover until the Upper Missouri River meets with the Yellowstone River.⁵⁰

Comment Text: We also ask that more research be conducted on the hypothesis that the velocity and turbulence of navigation channel may be fatal to free embryos of pallid sturgeon in the lower river. It is critical to determine if the navigation channel is lethal to the young pallids, and if so, then the upper portions of the navigation channel should be de-authorized. The DEIS reports that "river currents in the lower Missouri River are swift, and pushing loaded barges upstream is more costly in terms of fuel consumption," (V2- page 249). Recovery efforts that reestablish additional stretches of slow and shallow water would provide a multitude of benefits.

Organization: The Izaak Walton League of America

Commenter: Paul Lepisto **Page:** **Paragraph:**

Correspondence Id: 242 **Comment Id:** 645568 **Coder Name:** jgutierrez

Comment Text: The proposed alternatives are designed for the pallid sturgeon, least tern, and piping plover. However, many other native species will also benefit from these efforts. The DEIS (V2-page 127) refers to the many species that spend their entire life in the low-velocity areas of the river. These areas are lacking and we urge the Corps to implement recovery actions that return this type of aquatic habitat to the river to provide long-term, large, beneficial impacts to fish and wildlife. We encourage the Corps to implement recovery actions that restore needed habitat for the 51 of 67 native fish species that are rare or declining on the river. We believe this can be accomplished through restoring slow and shallow water habitat, levee setbacks, and river widening projects. In addition, also consider the species that have special-status designation at the federal or state level including 18 plants, 31 birds, 11 mammals, 18 reptiles and amphibians, 20 mussels, and 4 insects (V2-page 148).

Correspondence Id: 223 **Comment Id:** 644951 **Coder Name:** jgutierrez

Comment Text: The spring and fall flow releases found in Alternatives 4 and 5 do not represent a meaningful difference because their effects are virtually indistinguishable. Nor do the flow releases distinguish Alternatives 4 and 5 from Alternative 3 because they will take place too infrequently to matter. Although the flow releases are intended to "create ESH for the least tern and the piping plover," the MRRMP-EIS at no point discusses the amount of ESH that would result, stating simply that the flow releases will "be adjusted to respond to hydrologic conditions at the time."⁸⁵ Practically speaking, the years that the flow releases will not occur are far more frequent than the years in which they will occur partially or to completion. In terms of the modeling for Alternative 4, the MRRMP-EIS indicates that during the 82-year period of record (POR), "the spring habitat-creating flow release as defined here would have been implemented 10 times and would have been partially implemented 7 times."⁸⁶ This means that the flow release is only fully implemented 12.2% of the 82-year POR. The modeling for Alternative 5 indicates that during the 82-year POR, "the fall habitat-creating flow release as defined here would have been implemented 7 times and would have been partially implemented 2 times."⁸⁷ This means that the flow release is only fully implemented 8.54% of the 82-year POR. The infrequency of the habitat creating flow release raises doubt that the ESH goals of the 2003 Bi Op will be met through utilization of flow releases. The infrequency of the flow releases and the unlikelihood that the ESH goals of the 2003 Bi Op will be met show that Alternatives 4 and 5 are neither meaningfully different from, nor more effective than, Alternative 3.

Comment Text: The geomorphology of the Garrison Reach on the Missouri River is predominantly controlled by the interaction of Garrison Dam on the upstream end, and Lake Oahe on the downstream end (Skalak et al. 2013). Garrison Dam acts as a sediment trap and releases are essentially free of sediment. These releases have a high sediment carrying capacity and primarily erode the riverbanks and riverbed on the upstream end of the Garrison Reach. Further downstream, the sediment load of the flows increases. In addition, as flows move downstream, control of the geomorphology of the river channel transitions from Garrison Dam to Lake Oahe. The reservoir and its backwater effects decrease the sediment carrying capacity of the flows and causes aggradation. Therefore, the ability of the Garrison Reach, and the river in general to continuously create sandbar habitat with flows over the long term is questionable.

Comment Text: We concede that changing factors accompanying flow volume may have a different outcome. Increasing sediment releases from the retained material behind the mainstem dams along with flow may stimulate spawning cues. The failure to address sediment load throughout the DEIS is an inherent flaw of the entire exercise. Without additional sediment in releases the outcome is predetermined to be one thing - a waste of precious water. The Corps should develop alternative scenarios for flow releases of retained material in the reservoirs that increase sediment load downstream changing the flow cue strategy, or abandon all flow alternatives going forward.

Comment Text: Based on experience with AM on the Platte River NPPD believes that all habitat types should be considered and that if benefits to the species can be obtained by habitat creation, improvement or protection in areas within the Missouri River floodplain it should be in the list of potential management actions. Given the current data on movement between the alkali lakes in North Dakota and Lake Sakakawea and Oahe it would appear the alkali lakes provide a buffer for when conditions on the Missouri are bad such as in 2011 and hasten recovery when conditions improve. Likewise non-traditional habitats such as sand mines along the Platte River and ash pits near the Missouri River have documented successful plover reproduction. While creation of these habitat types may not be feasible at the scale that ESH is being contemplated they may provide opportunity for habitat where no other exists and actually increase the persistence of a population by expanding the occupied area. Experience on the Platte would indicate that anytime a statement is made about the longevity or cost of maintaining a certain habitat type is presented without data it should be scrutinized closely as it is often based on supposition and not fact.

Comment Text: The draft AMP at the instance of the USFWS takes a very narrow view of piping plover habitat defining it as having to be hydrologically connected to the main stream river or reservoirs. This view is not based in biology or insuring the continued existence of the species. Plovers thrive - successfully nest and survive in many habitats not hydrologically connected to the Missouri River. This approach appears to be related to mitigating impacts to the river and the effort to benefit and recover of the species has become secondary. A plover produced from an alkali lake, a reservoir habitat or other off river habitat contributes to the piping plover population the same as one produced on a Missouri River sandbar. Increasing recruitment from habitats not hydrologically connected to the rivers has same effect as increasing recruitment from ESH.

Comment Text: Comment 2: Pages 2-25 - 2-26 (121/190 -122/190) of DEIS Volume 1 DEIS describes reasons USACE has eliminated consideration of any meaningful actions at Fort Peck Dam: The water intakes for Fort Peck Dam are on the bottom of the

reservoir making it challenging to develop and implement design options to discharge warm surface waters downstream. In 2009, USACE completed the Fort Peck Dam Temperature Contra/ Device Reconnaissance Study. Ten alternatives to improve downstream water temperatures were evaluated for further consideration (USACE 2009b). The use of a flexible curtain to act as a submerged weir became the focus through subsequent investigations (USACE 2012b). This option uses a flexible curtain that is suspended a set distance from the water surface using a float system with the curtain bottom being anchored to the Joke bottom with ballast and anchors. This option works by passing the warmer water from the upper portion of the water column over the weir crest into the intake area, rather than drawing cold water from the bottom of the reservoir (USACE 2012b). USACE does not consider this option feasible due to an estimated short life cycle (i.e., 10-20 years), uncertainties with meeting downstream temperature targets, emerging science on larval drift distances, high construction and operation and maintenance costs, and significant dam operation safety concerns. Modeling predicts that if there is no delay in drift, then all combinations of aforementioned management actions on the Missouri River (alteration of Fort Peck flows, temperature modifications at Fort Peck, and drawdown of Lake Sakakawea) are likely to result in recruitment failure (Fischenich et al. 2014). As stated previously, a reconnaissance study conducted in 2009 cited the challenges presented by management options at Fort Peck Dam (USACE 2009b). Prohibitively high costs and/or risk and uncertainty related to dam operations and dam safety were associated with each option. Actively managing the hydrology below Fort Peck Dam to provide the appropriate volume and temperature at the correct time would be a significant challenge containing hydrological, physical, and biological uncertainty with a small probability for success (USFWS 2015b). Approximately 90 percent of the tagged adult pallid sturgeon in the upper Missouri River population use the Yellowstone River during the spawning period (May-July) (Braaten et al 2015). The only exception was during a historic flood when some fish chose the Missouri River, although most still chose the Yellowstone River. There is no evidence that pallid sturgeon could be attracted away from the Yellowstone River with reasonable manipulations in flow from Fort Peck Dam. Therefore, implementation of Fort Peck management actions or a drawdown of Lake Sakakawea were not retained for alternative development due to the high level of uncertainty regarding their feasibility to achieve desired biological results and documented issues regarding their technical feasibility. The AM Plan identifies a comprehensive framework for research and studies to address the uncertainty regarding the effectiveness of management actions for pallid sturgeon in the upper basin.

Comment Text: As the result of ongoing research, appears there may be potential for survival/recruitment of larval pallid sturgeon within the Missouri River below Fort Peck Dam (Ryan Wilson. pers. comm. 2017). The USFWS encourages consideration of MRRP actions within that reach of the Missouri River, pending the additional information and subsequent review. The following are

examples of potential actions the Corps should consider to expand the scope of the MRRMP/EIS: â€¢ Flow and temperature modifications - utilize surface water discharges from Fort Peck and Fort Randall Dams to increase river water temperatures; Implement summer low flows from Gavins Point, Fort Randall, and Fort Peck dams to increase seasonal water temperature and habitat heterogeneity; â€¢ Discontinue hydro-peaking from Fort Peck and Fort Randall dams to increase recruitment of pallid sturgeon; â€¢ Increase floodplain connectivity to allow for nutrient and sediment inputs; â€¢ Implement top-width widening to increase organic and sediment input and habitat diversity.

Comment Text: Section 2.5.1.4, Pages 2-16&17 - The USACOE's 2015 Annual Report for the Biological Opinion indicates that 40-50% of all piping plovers nests and fledglings are on the shorelines of Lake Oahe and Lake Sakakawea. These reservoirs account for a large percentage of the plover recruitment despite the fact that 80% of all incidental take of plover eggs and chicks occurs on these same shorelines. Because the DEIS does not differentiate between nests on riverine and reservoir shorelines except to document that most incidental take occurs on reservoir shorelines it is misleading the public, and the science, as to the true role of the reservoirs. It is possible reservoirs and the increased shore line habitat would be a benefit to piping plover. NPPD does not believe that water level management utilizing all reservoirs to reduce the instance of incidental take on Lake Oahe and Lake Sakakawea has been adequately addressed in the DEIS or the Draft Adaptive Management Plan (AMP). Additionally, constructed habitats that are designed to consider this fluctuation would also significantly benefit the success of the nesting birds.

Comment Text: Section 2.3, Page 2-5, Table 2-1 - With approximately half of all Missouri River plover nesting occurring on reservoirs and reservoirs also accounting of most of the USACOE take of plover nests (see page 2-16) it seems like one of the most relevant management hypothesis would be to reduce incidental take through reservoir management or habitat management on the reservoirs. Specifically water level management to create and provide habitat as well as minimize take of nests on Lake Oahe and Lake Sakakawea needs to be done in much more robust manner than what appears to have been done (see page 2-44). There may be some fairly minor management actions (raising levels in Lake Sakakawea a few days later) that may result in much less take of nests and increased productivity of this significantly important nesting.

Comment Text: Sediment transfer is a way to restore habitat and function to the Missouri and Mississippi River ecosystems while maintaining storage capacity for flood control, reducing bank erosion, and minimizing impacts on other uses of the rivers. The main stem dams trap sediment resulting in a less turbid river. According to the Recovery Plan for the Pallid Sturgeon (Recovery Plan),² pallid sturgeon historically occupied turbid river systems. ³ They adapted to this turbid habitat, so increasing the turbidity of the river will ostensibly benefit the pallid sturgeon.⁴ Taking sediment from behind the dams to increase the turbidity of the river also will help maintain the flood-storage capacity of the system. In addition, turbid water would erode banks less than clear water, all other things equal. Moreover, sediment transfer should not significantly impact the authorized purposes of the Missouri River Main Stem Reservoir System that rely on flow management or water temperature: hydropower, downstream power supply (thermal cooling), flood control, and navigation (provided the largely self-scouring design of the system is unchanged).

Comment Text: Lower pools also produce lower river flood damage reductions, and I hope you will consider an alternative that incorporates a lower storage target and navigation service levels, better unbalancing, and overall better management of pools for terns and plovers and other wildlife benefits. The Corps manages hundreds of miles of reservoir shoreline via water levels, and it's a shame to be overlooking opportunities for creative habitat enhancements over that long shoreline. [end of Michael Melius's comments]

Comment Text: Regarding terns and plovers in particular, the EIS discusses their nesting on reservoir (rsvr) shorelines, notably the issue of the rsrvs serving as ecological traps in some years. Yet I can't find where the alternatives address this problem directly, esp. by trying to prevent it. Rsvr unbalancing is the management technique that comes closest. Recent history shows it's been challenging for the Corps to carry out effectual unbalancing. I think they could try harder, and hope that the final plan will direct them to do so.

Comment Text: CMEPC supports a slightly revised Corps Preferred Alternative. The one revision to the Preferred Alternative CMEPC proposes is the addition of more off-channel, non-ESH work for plovers. As the work highlighted in the recent MRRIC Annual Forum (Michael Anteau, U.S.G.S., Conservation of Piping Plovers on the Missouri River: Thinking Beyond the Banks) suggests, there are productive habitat opportunities beyond the banks of the Missouri River that could prove very useful to piping plover recovery. CMEC believes that if the goal is to recover the species, it is imperative that for a societal economic as well as a species impact this work must be considered and implemented unless the science proves the benefits are not as robust as many believe they will be.

Comment Text: But beyond that, where are provisions for designation of critical habitat for the endangered pallid sturgeon; for unbalanced reservoirs to address the situation at a particular reservoir; for the application of the best science currently available? Habitat loss, fishing and caviar harvesting, entrainment and watercraft propellers, contaminants, hybridization, invasive species, and iridovirus all threaten the endangered pallid sturgeon. None of the alternatives provide adequate response. The pallid sturgeon requires shallow-water habitat. Designation of critical habitat is necessary! The Corps of Engineers seemingly acknowledges that with the phrase "avoid jeopardizing the continued existence of pallid sturgeon or its critical habitats" in the accompanying Draft Science and Adaptive Management Plan. Perhaps having unbalanced reservoirs as a management tool in the Missouri River Mainstem Reservoir System Master Water Control Manual is adequate, but perhaps not.

Comment Text: We're completely ignoring the saline lakes in South Dakota. The thing that started this whole thing was that, oh, if these birds don't nest in that 40 miles below Gavins Point, they won't nest at all. But the truth of the matter, that's a failed hypotheses. The number of birds that are there now and the number that were there at the 2011 flood is zero to 1,832. You can't go from zero to 1,832 in five years, no matter what you do, unless the birds are coming in from different locations. And the white paper that the Corps had worked with said there's only a 200th of a percent chance that this dispersal will take place, so that's bad science.

AL700 Alternatives: Actions Common to All Alternatives (Substantive)

Correspondence Id: 20 **Comment Id:** 626651 **Coder Name:** jgutierrez

Comment Text: The Draft Environmental Impact Statement out for comment contains six alternatives. Unfortunately, all six alternatives contain some level on increased flood risk via a spring rise. This runs directly contrary to the Corps flood control mission. In addition, there continues to be zero science that supports a spring rise and its benefit to pallid sturgeon. MCGA has never wavered in its opposition to the spring rise as a management tool. Though alternative three has less commitment to the rise, it still unfortunately leaves the door open. As mentioned before, science has failed to support a spring rise and therefore it should not be a component of any of the alternatives. We must not increase the risk of flooding during this critical time of year, planting season.

Comment Text: Of further consideration is the use of average temperatures for the lower River. KCMO routinely experiences high water temperatures during low flow periods coinciding with warm summer season. These high temperatures along with low turbidity normally associated with low summer flows create potential conditions for the formation of cyanotoxins. Although no firm maximum contaminant level has been established by EPA, Health Advisories have been issued by EPA and are defacto regulations of these compounds. In accordance with EPA Health Advisory, MO is one of the states," reviewing or developing an approach to address cyanotoxins in water. "(JAWWA Vol 109 p42.) Anecdotally KCMO has experienced "blooms" characteristic for cyanotoxins formation during previous low flow summer periods. No attempt was made to analyze for toxins as methods are just being developed and no EPA requirements were in place. This is no longer the situation. We are concerned that any Alternative considered with low summer flows may create river conditions requiring more extensive treatment than is currently required.

Comment Text: The DEIS (V1-page 150) focuses on hatchery practices. The League is concerned that the Corps places too much emphasis on hatchery raised pallids for the Missouri River. Stocking creates a population that is not self-sustaining. Our concerns about stocking also include disease and water quality issues in the hatcheries and the effects on the health of the fish raised. If hatchery pallids are transporting disease to wild fish, then restoration efforts are going backward. We also have concerns about the high cost of raising pallids in the hatcheries. We encourage more habitat restoration in the upper and lower river to ensure natural production and recruitment.

Comment Text: 3.11 - Commercial Sand and Gravel General Analysis: 1. Modifications in flow as presented in Alternatives 2, 4, 5 and 6 undermine the primary congressionally authorized purposes of navigation and flood control, making them problematic. 2. The states of Missouri, Kansas, Iowa and Nebraska own the bed of the lower river. The states have a sovereign right to their real estate and federal actions that compromise the real estates resources are a takeover in regard to states real estate and natural resources. 3. The use of the HEC-RAS model for decision making in the DEIS is flawed. Commercial sand dredgers have continually presented their objections to HEC-RAS being used for any permitting related decisions and the Corps has previously agreed during MRRIC sessions. In the DEIS however, this important point is missing from the document and needs to be included in the content for this section. 4. The DEIS fails to address the issue of sediment in the system and the lack of material movement. We call on the Corps to create a true sediment analysis that examines this important component for pallid sturgeon recovery. Changes in flow, without enhancing sediment load are not impactful and are a true waste of water in the system. 5. Regarding IRC construction and maintenance, the Corps must give commercial sand dredgers absolute assurance that these new habitat areas will not impact their operations by making its related regulatory strategy clear. Of utmost importance to dredgers are the issues of channel response, impacts to navigation, bed and hydraulic conditions.

Comment Text: Nearly all of the DEIS alternatives call for a shift in habitat construction to the building of 12 interception rearing complexes (IRCs) over the course of six years. We do not object to the advancement of scientific theory, including IRCs, as long as they are coupled with proper evaluation and introduced gradually. If the Corps is to truly follow the AM plan process, we suggest it take a measured approach regarding IRC construction and initially develop only one in the lower river. The Corps should first prove this theory's viability with one IRC site by constant evaluation before other IRCs are constructed. As part of the evaluation, the Corps has to ensure IRCs will not negatively impact activities within the channel such as navigation and commercial sand dredging.

Comment Text: The MRRMP-EIS includes spawning cue releases as a management action without adequately explaining their effects and without adequate knowledge of what the specific beneficial impacts of the actions would be on the species. The spawning cue releases in Alternative 2 must have two prerequisite characteristics: "(1) flows to cue spawning that are sufficiently high for an adequate duration; and (2) flows that provide for connection of low-lying lands adjacent to the channel."¹⁰⁸ Alternatives 3 through 5 "would include a one-time spawning cue test release from Gavins Point if Level 1 studies during the first 9-10 years do not provide a clear answer on whether a spawning cue is important."¹⁰⁹ In Alternative 6, "USACE would attempt a spawning cue release every 3 years consisting of a bimodal pulse in March and May."¹¹⁰ Each of these spawning cue releases could potentially be ineffective because "the exact characteristics of a spawning cue pulse that would elicit a spawning response are not known. The ISAP found no evidence that managed spring pulses are necessary to provide cues for pallid sturgeon spawning."¹¹¹ Therefore, the use of these potentially ineffective spawning cues would waste money and time that could be utilized on other management actions. It might be that the spawning cue is effective and that it will aid the pallid sturgeon. But the spawning cue should be analyzed over time while other management actions are being used to meet the species goals until the release is established as a viable management action.

Comment Text: Section & Page Number: 3.4.2.4, p. 3-98 **Comment:** Vegetation management is North Dakota's preferred method to obtaining target habitat acreages for piping plover and least terns in the Missouri River. Furthermore, the State of North Dakota recommends that the USACE maintain the agreed upon moratorium of management actions in the Bismarck-Mandan area where

management actions for piping plover and least tern are not implemented as decided upon by the North Dakota Interagency ESH Team. This would be from RM 1310 to RM 1325. Also, it is necessary to maintain a buffer of 1 mile around boat ramps with the same restrictions. This stretch of river supports a high volume of recreation. The attraction of piping plovers and least terns to the area by implementing management actions brings unnecessary human/bird conflicts. These conflicts would do more harm to the public perception of tern and plover recovery than the benefits the management actions would bring.

Comment Text: Section & Page Number: 3.2.1.3, p. 3-16 Comment: In Table 3-2, channel capacity based on hydraulic model results for the various Missouri River reaches are displayed. The Fort Peck to Lake Sakakawea Reach and the downstream portion of the Garrison Reach have estimated channel capacities of 35,000 to 40,000 cfs. Flows for any alternative should be managed to be at or below this level, unless impacts are mitigated.

Comment Text: Section & Page Number: 2.5.1.2, p. 2-15 and 2.8.1.1, p. 2-48 Comment: Due to the extremely temporal nature of existing sandbars in the Garrison Reach, North Dakota has long questioned the costs versus benefits of constructing artificial islands or sandbars in this area. Additionally, several of North Dakota's natural resource agencies have consistently opposed dredging or fill activities in the Garrison Reach (since the early 1990s), except for those public works projects that are of an emergency nature. As a result, regulatory agencies have taken a fairly conservative approach to issuing permits for projects of this nature. Implementing ESH projects that require dredging or fill would also no doubt create considerable new interest among private riparian property owners. North Dakota is in favor of mechanical creation as it relates to vegetation removal from existing ESH for the free-flowing stretches of the Garrison Reach. Should mechanical creation by buildup of sand in the river be necessary, to promote longevity of the project we recommend it only occur in the aggradating reach and in the Lake Oahe delta, but not between River Mile (RM) 1310 and RM 1325, and that the material used come from within the existing channel or preferably from the Oahe delta - pending approval of required state permits.

Comment Text: Section & Page Number: 2.5.1.1, p. 2-14 - 2-15 Comment: This section states that the ESH-creating flow release was retained as a management action for consideration in the MRRMP-EIS. This management action involves releasing high flows from the dams for the purposes of creating sandbar habitat for the piping plover and least tern. The ability of the Garrison Reach, and the river in general, to continuously create sandbar habitat with flows over the long term is questionable. Since construction of the dams, the geomorphic trend of the Garrison Reach is erosion at the upstream end, and aggradation on the downstream end. Skalak et al. (2013) showed that Garrison Dam exerts considerable morphological control on the channel until the backwater effects of the Oahe Dam and reservoir begin to influence the channel. The paper suggested that there would be a continued loss of islands in the upper portion of the Garrison Reach and management of habitat in this area would become more difficult. The paper also suggests

that management of habitat in the downstream portion of the Garrison Reach, especially in the Bismarck-Mandan area, would increase conflict between birds and people recreating on the river. Skalak et al. (2016) confirmed that large hydrologic pulses, such as the 2011 flood, do not revert the geomorphic pattern created by Garrison Dam and Oahe Reservoir, nor do they uniformly impact the different river zones or geomorphic features. Ultimately, the paper suggests that a change in conditions other than high-magnitude flooding would be required to return the Missouri River to its pre-dam condition, or restore the ecosystem to a self-maintaining state. Comment Text: Section & Page Number: 1.5.2, p. 1-23 Comment: The USFWS proposes using acres of ESH as a target to ensure a resilient population of birds on the Missouri River. Acres of ESH would be calculated in two ways: (1) Standardized ESH, and (2) Available ESH. It is not clear from the EIS and supporting documents why tracking Standardized ESH is necessary. For the Garrison Reach, the definition for Standardized ESH states that it is the area above water when releases from Garrison Dam are 23.9 kcfs. Releases from Garrison Dam do not always reach 23.9 kcfs in a given year. If the "standard" release does not occur in a given year, it is not clear how Standardized ESH is determined if it is not measured.

Comment Text: 4) Proposed frequency of enhanced flows is not supported by scientific evidence and is likely insufficient for pallid sturgeon recovery The Corps proposes flow modifications that would likely be of too little frequency to support pallid sturgeon recovery. If evidence exists to the contrary, the Corps should include them in the EIS. Examples of the limited flow releases are highlighted below. Each of these should be justified with statistics and data on historic flows to allow the public to assess the scientific validity and usefulness of the proposed approach to pallid sturgeon recovery. The EIS states that naturally high flow pulses

may trigger migration and aggregation of pallid and that other scientific studies of sturgeon species support this hypothesis. Additionally, a number of migratory species depend on pulse flows to trigger migration. Yet, the Corps states a "high degree of uncertainty is associated with this management action and it is possible that there could be no effect on pallid sturgeon."²⁹ It remains unclear how the Corps defines levels of uncertainty for pallid sturgeon recovery in light of the science supporting naturalized and pulse flows. Lastly, the Adaptive Management Plan states that pallid sturgeon adults will be tracked over a range of flow conditions over a period of nine years. After nine years, the Corps may then consider implementing spawning cues from Gavins Point. Implementing Dow-based modifications are critical for pallid sturgeon and native fish in the basin. Streamflow is viewed as a master variable,^{30, 31} one that shapes many fundamental ecological characteristics of riverine ecosystems. Entire foodwebs are altered as flows change, and in general less species survive in stressful low flow conditions. For fish, flow doesn't just influence oxygen levels, it influences all of life's necessities: temperature, habitat for spawning and escaping predators, and flushing sediment from the rocks on which many fish lay eggs. Scientific studies evaluating timing and duration of flows find fewer young-of-year fish, a disruption in spawning cues and an increased frequency of recruitment failures when the hydrograph is modified.³² Reservoirs in the Missouri River system have nearly reversed the timing and amount of water flowing through the river. Because flow is a controlling variable, it is critical that the Corps adopt and implement an alternative that takes flow into account. Since their construction, reservoirs on both the mainstem and tributaries of the Missouri River have tamed flows to produce a flat, controlled hydrograph that eliminates spring pulses from plains and mountain snowmel,³³ and leads to a decline in native fish and their prey.³⁴ Potentially important low flows in the Missouri River in the late summer and fall and winter disappear as water is used for downstream navigation and hydropower.³⁵ The dams also hold back nearly 80% of the historical sediment load, an important loss in a river dominated by native fish preferring turbid, warm waters.³⁶ The National Research Council of the National Academy of Sciences has recommended a more natural flow system, including a spring pulse to begin the recovery process. ³⁷ However it is recognized that this pulse may be insufficient³⁸ and the hope of inundating floodplains for fisheries would require a combination of higher flows, in-river and bank restoration, and selective floodplain easements.

Comment Text: 2) The Implementability and Viability of Proposed Alternatives is Questionable: The No Action Alternative and Alternatives 3 and 6 include flow modifications to Corps-operated reservoir releases to support the pallid sturgeon. These would require the Corps to implement minor, discrete changes in water releases from the reservoir to support spawning and reproductive cues. However, to date the Corps has not successfully implemented changes in reservoir operations to support pallid sturgeon recovery. As stated in the introduction, implementability is a key factor not considered in the EIS, as discussed below. Since 2000, FWS has

required a series of RP As from the Corps that would allow for recovery of a minor section of the natural hydrograph, including an approach that depended on concurrent, holistic implementation of flow regime modifications, habitat restoration, and the purchase and restoration of floodplain easements.¹⁵ In doing so, FWS set up a scientific experiment that, with full compliance, might have provided river managers and the Army Corps with critical information to modify reservoir operations for the benefit of not just the pallid, but also many native species and game fish in the Missouri RiYer system. These RPAs would have addressed some of the gaps in knowledge of the pallid sturgeon's life cycle by specifically implementing adaptive management practices, modifying flow to increase spring flows, decreasing summer flows, and implementing test flows from Fort Peck to understand the impacts of increasing temperature and flows concurrently. However, because the Corps has failed to implement most of the RP As, the FWS, and other scientists has been hamstrung and unable to adequately conduct scientific studies necessary for the recovery of the pallid sturgeon. Additionally, throughout the EIS the Corps incorrectly interprets and truncates the expert opinion of their own panel of independent scientists. For example, in Volume 2, p. 3-71, the Corps states: "The Missouri River Independent Science Advisory Panel (ISAP) considered the available information on the efficacy of flow pulses in relation to pallid sturgeon spawning and concluded "the spring pulse management action, as currently designed, is unnecessary to serve as a cue for spawning in pallid sturgeon." The statements and recommendations from the Independent Science Advisory Panel are stated below and clearly support enhanced flows and a number of other actions to support pallid sturgeon recovery. This resistance by the Corps to implement even a baseline set of recovery strategies for the pallid sturgeon was reflected in the 2013 Missouri River Recovery Program's Independent Science Advisory Panel's (ISAP) Report: There is " ... no evidence that managed spring pulses have improved ecological conditions for native fish, invertebrates, or other species, consistent with the observation that the pulses have been of such limited magnitude and durations that they appear to be unable to generate the specific habitat features and conditions that are believed to be important for those species" (emphasis added).

Comment Text: Many wild adult pallid sturgeon appear to be nearing the end of their lifespans⁹ and wild spawning is rare, ¹⁰ though has been demonstrated, particularly in the wake of high flow events. Additional limits placed on available habitat will likely continue the species on the path to extirpation. Not only would implementation of flow modifications potentially benefit pallid sturgeon, but it will benefit the entire fish community, including paddlefish, sauger, goldeye, blue sucker, and a vast array of other native species - a benefit that would contribute to the substantial recreational fishery. The Corps has instead decided to place downstream needs first, leaving the pallid sturgeon and other native fish to struggle to reproduce. We ask the Corps and sister agencies to take a hard look at their ability to implement the alternatives as stated. The Corps could 1) assess the likelihood that they

will implement each alternative, 2) establish a set of criteria that would place the needs of pallid sturgeon on - at a minimum - equal footing with downstream water users and 3) establish a set of performance criteria that would ensure accountability with the final alternative. To do this, the Corps will need to conduct additional analyses to inform the alternatives and their viability and scientific validity.

Comment Text: Pg. 42, Table 7 - So, after 6 years, there will be 12 pairs of IRCs and assessment will continue through for 10-11 years. Only after 10 years will implementation might begin. This is a long time. Couldn't the assessment begin with the first sets and be enough to at least put in more pairs? It just seems to be a delaying tactic - it will be 20 years before all 12 sites will have given the go ahead to fully implement! This clearly is a commitment to the special interests who don't want these things in or near the navigation channel.

Comment Text: Alternative 2 is described as meeting the minimum of floodplain connectivity as recommended by USFWS. But this seems absent entirely from Alternatives 3-6. But though the Corps speaks of Naturalization of the flow regime four times in Table 5 of the Adaptive Management Executive Summary, it doesn't discuss it in the text. Allowing for a natural flow regime, inundation of floodway/floodplain areas for re-connectivity as a result of naturalization of the flow regime is excellent and a far more sustainable way to recover habitat. We encourage the Corps to expand on this and continue this discussion more fully in the DEIS.

Comment Text: Scientific data indicates that previous spring releases have been ineffective as a spawning cue for the pallid sturgeon. The ISAPs 2011 Final Report on Spring Pulses and Adaptive Management indicates that spring pulses, as currently implemented, are not accomplishing their intended outcomes. Specifically, the ISAP Report concludes that the spring pulse management action, as currently designed, is unnecessary to serve as a cue for spawning pallid sturgeon. The more recent ISAP Evaluation of MRRMP v3 AM Plan and Pallid Level 3 Action, released in November 2015, states that the flow needs of the pallid sturgeon are imprecisely known at all life stages, therefore considerations of flow manipulations to benefit pallid sturgeon are now based on imprecise knowledge. This document further confirms that the Spawning Cue Flows action presents a hypothesis without compelling technical support. The Action Description of bi-pulse flows and frequency is very detailed, but without scientific justification. In addition, the Corps acknowledges in the DEIS that the exact characteristics of a spawning cue pulse that would elicit a spawning response are not known. AWO is opposed to any future spring or fall pulse/release that threatens navigation without scientific foundation.

Comment Text: Moreover, the mapping done by the Corps shows that "156,480 acres of floodplain connectivity are currently present, not including the area of the main channel," and the USFWS gave the Corps criteria which "stated that this management action should maximize floodplain habitat by ensuring that 77 ,410 acres of connected floodplain are inundated at a 20 percent annual chance exceedance." 100 The difference in acreage shows that improving floodplain connectivity of the Missouri River is an effective tool for benefitting the pallid sturgeon. However, the MRRMPEIS does not explain how floodplain connectivity would occur within the river, instead simply stating that "it is assumed that operations would result in floodplain connectivity of at least 77,410 acres as indicated by the mapping results described previously" for Alternative 2. 101 Alternative 2 is the only alternative that mentions floodplain connectivity, so it can be reasonably assumed that Alternatives 3 through 6 do not actually meet the floodplain connectivity goals. It is unclear why floodplain connectivity was not considered in Alternatives 3 through 6. The MRRMP-EIS states that there is "no implementation cost" to floodplain connectivity and so there is no economic reason not to consider the management action within the other alternatives. 102 Therefore, middle ground alternatives between Alternative 2 and Alternatives 3 through 6 should include varying levels of floodplain connectivity to ensure beneficial impacts to the pallid sturgeon.

Comment Text: Furthermore, the MRRMP-EIS does not sufficiently discuss the differences between SWH and IRC. While the MRRMP-EIS does assess the process of channel widening, the types of needed habitat for the pallid sturgeon, and the types of structures, nowhere does it explain which types of structures would need to be utilized. The IRC habitat also requires additional "research and assessment to determine whether and why IRC's contribute to increased growth and survival," meaning that it is possible that IRC's may not be beneficial to the pallid sturgeon. 76 In contrast, the creation of SWH does not have the same level of uncertainty. Because of the difference, SWH and IRC should not be considered comparable or interchangeable techniques for habitat creation. The MRRMP-EIS does not specify what would happen if the results of the research on IRC show that it does not benefit the pallid sturgeon. If the results are negative and there is no substitute action, then Alternatives 3 through 6 lose a large portion of their beneficial effects for the pallid sturgeon. It is therefore unclear why there are no alternatives in which both SWH and IRC habitat creation are proposed. While they have the same goal of providing benefits to the pallid sturgeon, they are different methods of achieving this goal and thus it would be reasonable to include variations of both in the alternatives analysis.

Correspondence Id: 223 **Comment Id:** 644946 **Coder Name:** jgutierrez

Comment Text: The amount of land and SWH creation in Alternative 2 is drastically different than the amounts of IRC that are outlined for Alternatives 3 through 6. Those alternatives make no mention of how the acreage of IRC relate to the 2003 BiOp's species goals, nor do they mention how many acres of habitat would actually be constructed. They do state that approximately 260 acres of channel widening would occur per year in 13 out of the 15 years, reflecting about 3,380 acres of "accommodation space for new IRC habitat."71 This amount of acreage would require 230 acres of acquired habitat land and 1,772 acres of total additional acquired land.72 The difference in acreage of early life stage habitat construction is large between Alternative 2 and Alternatives 3 through 6. While Alternative 2 creates almost 10,000 acres of SWH through channel widening, it is unlikely that the 3,380 acres of channel widening found in Alternatives 3-6 would create IRC in an amount anywhere close to Alternative 2. The gap between the amounts of habitat created in Alternative 2 and Alternatives 3-6 calls for the consideration of other viable alternatives. Alternative 2 discusses how many acres of habitat would be created through channel widening but makes no mention of how many acres of channel widening would occur, and Alternatives 3 through 6 do not mention how many acres of habitat will be created but do mention how many acres of channel widening will occur. The MRRP-EIS uses different sets of units in Alternative 2 and Alternatives 3-6 and fails to explain the correlation between them. However, when describing Alternative 3 in Tables 2-20 and 2-21, the units change but the numbers stay the same. 73 For example, Table 2-20 has a column with the heading "Target Acres of Channel Widening." Table 2-21 uses those same values in a column headed "Target Acres of SWH."74 This creates confusion over the meaning of the acreage

numbers and makes it impossible to assess the validity of the range of alternatives based on the early life stage habitat management action. The data is inconsistent and cannot be directly compared. Table 3 below outlines the amount of early life stage habitat created by Alternative 2 in comparison to Alternatives 3-6, showing a 68.6% difference in target acreage. It is difficult to believe that this significant difference in acreage does not impact the alternatives' ability to meet species goals. [Table 3: Target Acres of Shallow Water Habitat in Alternatives]

Comment Text: Alternatives 3 through 6 include the creation of ESH in slightly different amounts. Those differences are small, especially when compared to the differences between Alternative 2 and Alternative 3, and may not be correct due to the uncertainty of the effects of flow releases on habitat creation. To meet the 2003 BiOp's recommended 11,886 total acres of ESH creation, the USFWS has recommended subdividing ESH construction on segments of the river: Below Garrison Dam - 50 acres of ESH per river mile Below Fort Randall Dam - 20 acres of ESH per river mile Lewis and Clark Lake - 80 acres of ESH per river mile Below Gavins Point Dam- 80 acres of ESH per river mile⁵¹ The MRRMP-EIS presents the ESH data in terms of: average ESH construction in build years, average ESH construction in all years, percent of years construction is anticipated, the 2.5% construction amount, the median ESH construction amount, and the 97. 5% construction amount. ⁵² When comparing all of these values for Alternatives 3 through 6, Alternative 3 has the highest value in each category and Alternative 4 has the lowest value in each category. ⁵³ While these high and low values for Alternatives 3 and Alternative 4 vary greatly in comparison to each other, they barely compare to the differences between Alternative 2 and Alternative 3. That discrepancy can be seen in Table 2 below in the category of average ESH construction in build years. Alternative 2 would achieve 3,546 acres of ESH, Alternative 3 would achieve 391 acres of ESH, and Alternative 4 would achieve 240 acres of ESH. ⁵⁴ Therefore there is an-160.3% difference between Alternative 2 and Alternative 3, making the difference between Alternative 3 and Alternative 4 (the alternative with the least ESH creation between Alternatives 3 through 6) negligible. Table 2 shows these extreme differences between the alternatives for ESH construction: [Table 2: Average Emergent Sandbar Habitat Construction] The differences in ESH creation among Alternatives 3 through 6 are negligible: "under Alternative 3-6 mechanical construction amounts vary because this management action would be used to create enough ESH to meet bird habitat targets after accounting for the amount of ESH created by System operations under each alternative."⁵⁵ Therefore, those four alternatives would be creating virtually the same amount of ESH.

Correspondence Id: 223 **Comment Id:** 644943 **Coder Name:** jgutierrez

Comment Text: 1. The differences in mechanical emergent sandbar habitat construction are unreasonable. One of the most dramatic differences separating Alternative 2 from the remainder of the alternatives is the relative amount of mechanically constructed ESH and its associated costs. Alternative 2 would have the Corps construct about nine times more ESH per year than the next highest amount of Alternative 3 (3,546 acres versus 391 acres).⁴⁵ The MRRMP-EIS states that construction amounts vary to reflect what would need to be built after accounting for ESH created by flow releases. However, the amounts of ESH created by the various flow releases of Alternatives 3 through 6 are nowhere clearly identified. In fact the Corp's 2011 EIS, which was devoted to analyzing ESH construction, affirmatively concluded based on prior Corps studies that flow releases were not an effective or certain means of ESH creation to meet the goals of the 2003 BiOp.⁴⁶ The MRRMP-EIS's reliance on flow releases in the context of required ESH construction is therefore highly questionable. Alternative 2's ESH construction is projected to cost \$8.6 billion over 50 years (relative to No Action), which is more than half the total Alternative 2 implementation cost of \$15.8 billion.⁴⁷ Moreover, Alternative 2 is the only alternative that yields a net increase in total implementation costs, and the cost increase is 378%.⁴⁸ Table 1 below compares each alternative's ESH construction amounts, total program expenditures, and the percentage increase or decrease of program expenditures relative to the No Action Alternative:⁴⁹ [Table 1: Emergent Sandbar Habitat Construction] Considering the expenditures necessary to meet Alternative 2's ESH targets, Table 1 shows that the range of alternatives is unreasonable under NEPA based on ESH construction alone. The Corps does nothing more than intimate that the flow releases of Alternatives 3 through 6 may bridge the gaps in ESH between Alternative 2 and the rest by creating sandbar habitat through sediment deposition: "flows that are high relative to the elevation of existing sandbars have the potential to mobilize and deposit sediment at high enough elevations to create new sandbars when water levels recede," and "the amount of habitat created depends on the magnitude and duration of the flow release and the area of sandbar present prior to the release."⁵⁰ The Corps provides no details on estimated amounts of ESH created through flow releases.

Correspondence Id: 245 **Comment Id:** 644915 **Coder Name:** jgutierrez

Comment Text: There appears to be weak support for the benefits of channel widening to recruitment of age-0 pallid sturgeon, particularly given its proposed high cost. IRCs are proposed in the DEIS and supporting documents to be superior to SWH for pallid sturgeon age-recruitment, yet channel widening is the management action proposed to create both SWH and IRC projects under alternatives 1 and 2 (SWH) and 3-6 (IRC) . A major purpose of the no-action alternative is as a comparison or reference against which to evaluate all other alternatives. It appears the proposed no-action and BiOp alternatives misrepresents what management

actions were taken in the past to create SWH by largely equating SWH creation to channel widening and grossly overestimating construction costs. Inflating the costs for the no-action and BiOp alternatives relative to historical expenditures prevents the public and resource management agencies from accurately evaluating proposed alternatives including the preferred alternative against the no-action-(alternative 1) and BiOp alternatives (alternative 2). RECOMMENDED ACTIONS TO RESOLVE. Clarify why channel widening appears as the proposed primary management action to create SWH under Alternatives 1 and 2 and also IRCs under alternatives 2-6 when was it seldom be employed by the MRRP to create existing SWHs and when the AM Plan (e.g. Section 4.2.6.3.5) states that while IRCs and SWH share some attributes, they are different relative to food production and foraging habitat. Provide explicit evidence for the anticipated benefit to cost of channel widening to achieve IRCs and review the 'best available science' that shows IRCs are superior to SWH (not hypothesized benefits), or other channel reconfigurations when SWH has not been shown to benefit recruitment of age-0 pallid sturgeon (e.g., Schapaugh et al 2010; Schloesser et al. 2012). What alternative hypotheses (under an active AM approach) were considered to create pallid sturgeon early life history habitat and the science to support them? Revise proposed management actions and associated costs for SWH construction for the no-action and BiOp alternatives to reflect historical actions employed and actual costs used to create SWH, or justify why the proposed no-action and BiOp alternatives SWH proposed costs to continue the existing program have escalated so much. Revise proposed costs for IRC construction via channel widening for alternatives 3-6 to be in line with observed costs to create the 3 identified IRCs or justify why proposed costs for any additional IRCs have escalated so much.

Comment Text: Additionally, channel widening is described (2.5.3.1) as a type of channel reconfiguration distinct from structure modifications (e.g., bank notches, dike notches, revetment notches and lowering), placement of new structures (e.g., chevrons, rootless dikes, and reverse sills), and off-channel habitat (e.g., creating of chutes and backwaters). The fact is channel widening has never been a primary mechanical action employed to create SWH between 2004 and 2013. Evidence for this comes from the Corps map of mitigation sites (file:///C:/Users/galatd/Downloads/SWH ESH llx17 2013opt.pdf) which identifies 64 SWH-ESH sites along the Lower Missouri River and the management actions used to create them. Only one of the 48 SWH sites (Deer Island - under construction as of 2013) lists channel widening as the primary mode of construction. Chutes, backwaters, dike notching, bank notching and revetment lowering were the management actions used to create the remaining 47 sites. Additionally, Table 47 P 379 of the DEIS Vol 2 indicates that channel widening was employed as a main channel modification in only 3 of 2,173 SWH construction actions. With so little past emphasis on employing channel widening to create SWH it is no surprise that there is scant scientific evidence for it benefitting pallid sturgeon recruitment. Why then has it channel widening become the proposed management action of

choice for all DEIS for early life history habitat construction alternatives? Lastly, in the DSAMP channel widening is indicated to be the primary management action proposed to create IRCs: (P88, L10-13): For the purposes of evaluating potential impacts to the human environment, modeling assumed that about 3,380 acres of channel widening would be implemented to create IRCs under Alternatives 3-6 (Table A.3.9). Collectively these excerpts from the DEIS and supporting documents indicate that channel widening is the primary management action proposed to be implemented to create IRCs (or SWH under alternatives 1 and 2) to benefit pallid sturgeon early life history - considered the most critical

Comment Text: STATEMENT OF CONCERN 2.1. Channel widening is the largest expense under Early Life History Habitat construction and the largest single expense of all management actions for all alternatives. Nevertheless, its potential benefit to pallid sturgeon early life history recruitment is circumstantial at best and not supported by the effects analysis. 2.2. The proposed cost of channel widening to create additional SWH (largely by channel widening) under the no-action alternative appears unrealistically high relative to historical costs for creating SWH under the MRRP. 2.3. The proposed cost of channel widening to create IRCs under alternatives 3-6 appears unrealistically high relative costs proposed for IRCs already identified. BASIS FOR CONCERN 2.1. What is channel widening and how will it benefit age-0 pallid sturgeon recruitment? Channel widening or top-width widening is described as follows (2.5.3.1): Channel widening projects involve the use of mechanical equipment to lower the adjacent floodplain and bank of the Missouri River to create habitat and widen the top-width of the river channel. Excavation is typically performed by hydraulic dredge. Some of the excavated material would be distributed in the main channel adjacent to the excavation zone. The remaining material would be discharged into the thalweg of the Missouri River where it would become entrained into the bedload of the river. For clarification, under Table 2-14 channel widening is described as a type of shallow water habitat creation under the no action Alternative 1 and in section 2.8.4.4 channel widening was identified as the primary means to develop IRC habitat (p 2-67). Thus importantly, the same action identified a primary means to create SWH under the 2003 BiOp (alternatives land 2) is also proposed to be applied to create IRC habitat under alternatives 3-6, including the preferred alternative (#3). The raises the obvious question of how SWH and IRCs differ other than identifying interception, and rearing as the function of IRCs - as if these functions were not implied for SWH if age-0 pallids were to settle and survive there!

Comment Text: TNC is concerned at the characterization of the Alternative Development process throughout the draft MRRMP-EIS. As stated at the beginning our comments, TNC has been and is supportive of this unique EIS process and its products, and believes USACE should apply the process in other appropriate areas. TNC believes it is important to accurately capture the alternative development process as it pertains to MRRIC involvement in the MRRMP-EIS and requests USACE do this by addressing inadequacies parts of Section 2.1- Overview of Alternative Development Process and the Pallid Sturgeon and Bird Alternative Development sections. Instead of detailing the inaccuracies, TNC believes a basic and accurate overview of the alternative development process involving MRRIC would contain: An initial set of alternatives were developed by the MRRMP-EIS Product Development Team (PDT) and the Effects Analysis Teams. This initial set of alternatives was shared with MRRIC members through a series of Human Consideration Proxy Webinars. After the webinars, the initial set of alternatives was revised by MRRMP-EIS PDT and presented and discussed to MRRIC at the May 2015 Plenary meeting. At this meeting MRRIC members could share their initial reactions verbally and could provide written feedback and ranking of alternatives if they chose to. No specific or deliberate alternative trade-off discussions or interest-based negotiations with MRRIC were held at or after the meeting. After the May 2015 meeting the MRRMP-EIS PDT revised the initial and developed a second set of alternatives which were presented and discussed at the August 2015 MRRIC Plenary meeting. Again, no specific or deliberate alternative trade-off discussions or interest-based negotiations with MRRIC were held at or after the meeting. After the August 2015 Plenary meeting, the MRRMP-EIS PDT analyzed the second set of alternatives and forwarded six "plan" alternatives (including a No Action alternative) for detailed evaluation in the draft MRRMP-EIS.

Comment Text: Interception Rearing Complexes (IRC's) are a new methodology proposed under all alternatives for pallid sturgeon population improvements. They are unproven and untested. They are experiments and hypothetical. Like prior shallow water habitat proposals such as chutes and channels, these experiments need to be field tested to determine their success. We believe the prospects for success of IRC's are favorable and do not object to them being introduced with proper caveats. As presented, IRC's will be adjacent to the navigation channel, should not impact the channel or navigation, and address various early life stages of the pallid. Their development is based upon field observations. None have ever been designed. None have ever been tested. There is NO justification presented for advancement of numerous modifications adjacent to the channel for IRC's until one or two have demonstrated success for the stated purpose. The Corps and FWS intend to jump into IRC development with both feet based upon the DEIS and presentations at MRRJC, advancing a dozen IRC prospects. We object, not to the principal and experiment, but to what we believe is an overzealous response to an unknown idea.

Comment Text: 10. Interception Rearing Complexes are, by both the Fish & Wildlife's ("FWS") and Corps' admissions, experiments. We do not object to the advancement of hypotheticals, including IRC's, provided proper evaluations are performed and a graduated introduction taken. We believe the Corps is moving too quickly with regard to the IRC hypothesis and therefore avoiding the adaptive management process. We suggest that only one IRC be developed in the lower river, that it have constant evaluation regarding impacts on channel integrity where structures are modified to create these types of complexes, have enhanced data collection, and then evaluated by the adaptive management team for success prospects prior to implementation of other IRC's.

Comment Text: The MRRMP does not advance pallid sturgeon recovery or improvements to pallid sturgeon habitats impacted by USACE operations in Montana, as no management actions are planned to occur during the fifteen-year timeframe of this plan. I do not consider USACE funding of Intake as a USACE management action to benefit pallid sturgeon as this project 1) does not address USACE-caused take of pallid sturgeon in Montana and, (2) the project's primary purpose is to provide water to eastern Montana irrigators, not recover pallid sturgeon. But the work at Intake and its expectations and outcomes are not within the scope of this letter.

Research is not a management action. The approach of the MRRMP is to take no management actions until the related science is conducted at the peer-reviewed publication level. State management agencies have successfully managed and recovered wildlife populations without this level of science. The MRRMP process only delays implementation of needed management actions by requiring prior and often redundant research into the minutiae of already successful Upper Basin pallid sturgeon programs such as propagation and stocking.

Comment Text: As the result of ongoing research, appears there may be potential for survival/recruitment of larval pallid sturgeon within the Missouri River below Fort Peck Dam (Ryan Wilson. pers. comm. 2017). The USFWS encourages consideration of MRRP actions within that reach of the Missouri River, pending the additional information and subsequent review. The following are examples of potential actions the Corps should consider to expand the scope of the MRRMP/EIS: â€¢ Flow and temperature modifications - utilize surface water discharges from Fort Peck and Fort Randall Dams to increase river water temperatures; Implement summer low flows from Gavins Point, Fort Randall, and Fort Peck dams to increase seasonal water temperature and habitat heterogeneity;. â€¢ Discontinue hydro-peaking from Fort Peck and Fort Randall dams to increase recruitment of pallid sturgeon; â€¢ Increase floodplain connectivity to allow for nutrient and sediment inputs; â€¢ Implement top-width widening to increase organic and sediment input and habitat diversity.

Comment Text: Specifically, it should be recognized that success may ultimately only be achieved through the implementation of an array of actions which are not currently contained in any one alternative in the Draft MRRMP EIS. To facilitate a more robust approach to adaptive management the USFWS recommends the Corps include a broader spectrum of potential management actions (including flow actions which are described in other alternatives) in the final selected alternative. A more thorough evaluation of when such actions may take place while minimizing impacts to stakeholder interest should also be conducted. The USFWS recognizes many of these additional actions may not be implemented immediately, however, having them accessible pending a myriad of potential needs and conditions exemplifies a robust and needed adaptive management approach. A final solution may include elements of the alternatives currently presented in the Draft MRRMP EIS and recommendations presented in this letter.

Correspondence Id: 183 **Comment Id:** 643922 **Coder Name:** jgutierrez

Comment Text: The USFWS is also concerned about the commitment of the Corps to implementing actions sufficient to achieving the purpose and objectives of the Draft MRRMP/EIS. As intimated above, the vast majority of efforts are Level 1 and Level 2 in nature, in which no population level response is expected by the species the pathways, criteria and descriptions to Level 3 actions (actions at a magnitude where a population response is expected), are often ambiguous and in many cases not defined, and require more clarity/definition in the Final MRRMP/EIS.. Moreover, Level 4 management actions, the ultimate scale of implementation to remove a limiting factor, are for the most part non-existent within the Draft MRRMP/EIS. (Reference Table 4-1 within Volume 1: Summary of Time Limits for Level 3 Implementation and Scope of Actions). The USFWS has maintained that commitment to action both in the context of continuous learning through adaptive management as well as in the face of ambiguous or equivocal results is essential to success. The USFWS recommends clearer articulation of commitment for implementation to Level 3 actions. The Corps should define and analyze the scope of Level 3 actions for all proposed management actions to remove ambiguity or in many cases absence of management actions at Level 3.

Comment Text: Section 2.9.2.1, Page 2-78 - Alternative 1 is not an appropriate baseline case under NEPA and based on the science it does not benefit the species, with regard to pallid sturgeon spring pulses and SWH. Additionally spring sturgeon pulses which are carried through the 82 period records have in reality been implemented very infrequently. Additionally the SWH has not been developed to anywhere near the level of the no action alternative. As such it is not a reference or base case and really represents impacts of the alternatives that have not been realized. Additionally the impacts to thermal power, should not be compared to the impacts modelled for Alternative 1 in an incremental or comparative manner as done in the DEIS. The DEIS must present the NED and RED results for each alternative in a total and individual manner as is done in the hydropower section. The comparison of impacts of Alternatives 2-6 to Alternative 1 as presented makes the impacts appear less than as currently described in Alternative 1.

Comment Text: While the preferred alternative, Alternative 3, and other new Alternatives, 4, 5, and 6, cost less than the Alternative 2, in our agency's opinion other than for IRC and spawning habitat, they lack action to address the previously identified habitat losses that we believe are necessary to support all life stages of Pallid Sturgeon as well as a substantial prey base upon which they as a top predator ultimately depend. As stated previously, the Nebraska Game and Parks Commission believes that the habitat goal of 20 to 30 acres of aquatic habitat per mile remains the most fundamental means to address the critical needs of Pallid Sturgeon and the native fish community upon which they depend. And rather than just building habitat of general design, this effort could be greatly improved by targeting specific habitat needs for both Pallid Sturgeon and the native fish community. Functional habitat can be built on the Missouri River as has been demonstrated at Deer Island on the main channel and at the Upper and Lower Hamburg Bends and Deroin chutes off channel. Means to develop a targeted habitat restoration program have recently been developed by biologists at Nebraska Game and Parks and the Missouri Department of Conservation. We also believe that the costs to implement Alternative 2 would be substantially reduced by replacing the impracticable target of 3,546 acres per year with the much more reasonable target described in Alternative 4.

Comment Text: Additionally, any alternative that includes low summer flow provisions should be removed from the Corps' consideration due to its impacts on navigation and public utility operations. Low flows would kill the navigation industry, which has seen a recent resurgence due to improved conditions on the river. Commercial navigation is dependent upon flow certainty and there are numerous advantages to increasing utilization of our inland waterway system. The combination of water-compelled rates and the importance of flows from the Missouri River to the Middle Mississippi River should spell doom for any serious consideration of

summer low flows. The Missouri River's role as a marine highway will only become more important as U.S. farmers continue seeking new markets for their products.

Comment Text: Even considering that the chart the Corps provided as a summary document is especially poorly presented and misleading. This chart is found in the executive summary page xxvii and in the glossy thirty one page document which served as the primary handout to the public. The chart uses different metrics for different impacts. This makes comparisons difficult. How to compare digits one and two to the dollar ratings in other categories. The fact that the chart rates all alternatives the same for ecosystem services is absurd. Costs and expenditures are totals, when in the text we know that ranges are available and all alternatives include great uncertainty is how much of several proposed actions will actually be performed. This was a point explained at MRRIC meetings, but is not reflected in the expenditure chart. And of course per our comments on Alternative 2, the large cost is largely based on an unrealistic projection.

Comment Text: Throughout the DEIS it often appears that human considerations are almost solely driving decision making. The DEIS is not forthright on the degree to which the Corps is placing what it has defined as human considerations in its determinations. The agency seems to operate on the assumption that the first priority for recovery actions is that they impinge little or none on any other consideration. Again this first principle keeps the Corps from considering longer term ecosystem restoration goals as a way to species recovery. In the long run, restored and mitigated acres with predictable flow modifications would do more for recovery. That approach also would have benefits of flood risk reduction and recreation enhancement on river stretches. And in the long run would cost less and limit the disruption of excessive ongoing mechanical habitat creation. It could eventually provide more modest impact on other uses.

Comment Text: We have concerns with each of the six alternatives in the DEIS. In general, with the exception of Alternative 1 (No Action), each of the alternatives relax current flood control constraints within the Missouri River Reservoir Mainstem Water Control Manual (Master Manual) in an effort to provide flow support to the pallid sturgeon. Not accounting for additional rainfall, this could equate to an increase in a river stage of nine feet at Omaha, NE or as much as six feet at St. Joseph, MO. We believe the only way the Corps can implement flow changes is through a Master Manual revision, of which we have long opposed. In 2015, twenty members of Congress from Missouri to Montana went on record in a letter to then Asst. Secretary of the Army Jo Ellen Darcy, urging the Corps to not implement a plan that would cause such revision, nor one that would incur damaging impacts to stakeholders and landowners.

Comment Text: By proposing such a wide range of alternatives or options it appears to me that you are only guessing at what may save the endangered species. There should be proven science behind these options before implementing any of them. Any excess water stored behind the dams to implement your alternative or option is a flood risk. You are unnecessarily risking lives and property with these plans. I believe the most important consideration in this project should be flood control to protect the businesses, personal properties, farmland and human life that has flourished along the river for many generations. That was the number one reason the system was built in the first place and it should still be the number one reason to maintain it. If even one person were to lose his or her life due to unnecessary flooding of the river it would be too high a price to pay just to potentially save our endangered species.

Correspondence Id: 35 **Comment Id:** 628391 **Coder Name:** jgutierrez

Comment Text: I'm here tonight to remind the Corps of their flood control mission. The Draft Environmental Impact Statement contains six alternatives. I find it appalling each alternative increases the risk of flooding. It is clear the Corps and Fish & Wildlife Services turned their back on flood control. All the alternatives - - all the alternatives propose a spring or fall rise. Alternatives 4 and 5 represent the most audacious lack of concern for the citizens impacted by Missouri River management. The 60,000 cfs release found in these two alternatives is an outrageous demonstration of the Corps' disregard for and the failure to pursue its flood control mission.

Alternative 1, 2 and 6 contain lesser rises, but still threaten those downstream with increased flows. Alternative 3 contains a stipulation containing its own possible spring rise after a few years of monitoring. This caveat is an open door for those managing the river to dump more water on those downstream. At what point will the United States Army Corps of Engineers understand it is wrong to intentionally flood those they have been directed to protect?

Comment Text: My first thoughts on that, since my career was in excavation, if we're going to artificially create nesting habitats and sandbars, artificially made sandbars, I just know, from experience, that the cost per fledged bird will be just astronomical and just a terrible waste of taxpayer money. And I think that money could be well - - spent better to use to buy habitat. Or, in my mind, when I see how many birds are produced on some of these sandbars along the lower Platte River, much less money could be spent creating habitat off the river, buying and creating habitat, put sand out there, put water out there, put an electric fence to prevent predators from coming in. And as far as taxpayer dollars per bird that you'd spend on a fledged bird, it'd be a lot less, I'm very sure.

Comment Text: The DEIS (AMP 2-page 221) states that the budget will determine the extent to which management actions can be implemented. Mechanical habitat construction and modification are most likely to be constrained by budget, and other management, monitoring, and research activities may also be constrained. Again, this is the primary flaw with Alternative 3. The League is sensitive to the probability of future funding being jeopardized by Congress, bringing recovery efforts to a complete halt. The Corps should address these funding concerns in the final EIS.

Comment Text: Land for acquisition has been valued in the document at \$4000-6000/acre. Although a mix of land valuation has been used, most of the land along the river that would be acquired is not top-quality farmland and the \$4000-6000 range is too high. Much of that land is sandy (from centuries of the river moving back and forth and depositing light silt and sand) or a mix of sand and clay. Additionally, many pieces of land along the river offered by willing sellers are irregular in shape, making farming with large machinery more difficult to do and less desirable. The irregularity also means there are corners and patches of shrub and wooded vegetation and uneven terrain. Also, land prices have been declining in the last 12 months, and as long as grain prices remain low (grain buyers have predicted low prices to continue into the significant future because of increased production in South America and Asia), land prices will continue to decline. The cost of land has therefore been over-priced in Alternative #2.

Comment Text: There appears to be weak support for the benefits of channel widening to recruitment of age-0 pallid sturgeon, particularly given its proposed high cost. IRCs are proposed in the DEIS and supporting documents to be superior to SWH for pallid sturgeon age-recruitment, yet channel widening is the management action proposed to create both SWH and IRC projects under alternatives 1 and 2 (SWH) and 3-6 (IRC) . A major purpose of the no-action alternative is as a comparison or reference against which to evaluate all other alternatives. It appears the proposed no-action and BiOp alternatives misrepresents what management actions were taken in the past to create SWH by largely equating SWH creation to channel widening and grossly overestimating construction costs. Inflating the costs for the no-action and BiOp alternatives relative to historical expenditures prevents the public and resource management agencies from accurately evaluating proposed alternatives including the preferred alternative against the no-action-(alternative 1) and BiOp alternatives (alternative 2). RECOMMENDED ACTIONS TO RESOLVE. Clarify why channel widening appears as the proposed primary management action to create SWH under Alternatives 1 and 2 and also IRCs under alternatives 2-6 when was it seldom be employed by the MRRP to create existing SWHs and when the AM Plan (e .g. Section 4.2.6.3.5) states that while IRCs and SWH share some attributes, they are different relative to food production and foraging habitat. Provide explicit evidence for the anticipated benefit to cost of channel widening to achieve IRCs and review the 'best available

science' that shows IRCs are superior to SWH (not hypothesized benefits), or other channel reconfigurations when SWH has not been shown to benefit recruitment of age-0 pallid sturgeon (e.g., Schapaugh et al 2010; Schloesser et al. 2012). What alternative hypotheses (under an active AM approach) were considered to create pallid sturgeon early life history habitat and the science to support them? Revise proposed management actions and associated costs for SWH construction for the no-action and BiOp alternatives to reflect historical actions employed and actual costs used to create SWH, or justify why the proposed no-action and BiOp alternatives SWH proposed costs to continue the existing program have escalated so much. Revise proposed costs for IRC construction via channel widening for alternatives 3-6 to be in line with observed costs to create the 3 identified IRCs or justify why proposed costs for any additional IRCs have escalated so much.

Comment Text: [IRC Project Costs table] 1. June 2016. PROJECT IMPLEMENTATION REPORT WITH INTERGRATED TIERED ENVIRONMENTAL ASSESSMENT, FINDING OF NO SIGNIFICANT IMPACT AND SECTION 404(b)(1) EVALUATION, Langdon Bend Interception and Rearing Complex Habitat Project. USACE Omaha District 2. May 2016. Missouri River Recovery Program - Environmental Assessment & Section 404(b)(1) Evaluation Searcys Bend Interception-rearing-complex Habitat Project. USACE, Kansas City District 3. July 2016. MISSOURI RIVER RECOVERY PROGRAM - July 209 Baltimore Bend Interception Rearing Complex Project. Definite Project Report and Integrated Environmental Analysis & Section 404(b)(1) Evaluation. USACE, Kansas City District SIGNIFICANCE OF CONCERN. The DEIS falsely presents channel widening and the comparatively high costs associated with it as a primary management action to create SWH under alternatives 1 and 2. The historical evidence indicates that other management actions were used to create the majority of SWH sites and at a much lower cost than is presented in the DEIS and specifically the Cost Estimates Table in appendix F.

Comment Text: 2.3. What does it cost to build an IRC? Under the preferred Alternative (Alternative 3 - Pallid Habitat Construction & ESH Mechanical) average annual costs for IRC construction in the Kansas City Reach is \$40,181,427 (39% of total program costs). According to the DEIS, two IRCs will be constructed per year over six years in this reach to yield a total of 12 for the Level 2 phase.

Thus, on average the proposed total cost to acquire and build a typical IRC is about \$20,090,173. At least three IRCs have already been identified and EAs published: Langdon Bend, Searcys Bend and Baltimore Bend). Table IRC Project Costs summarizes total project costs and can be used to approximate what average annual total costs for 2 IRCs per year might be - assuming these represent typical future IRCs? The average total cost is per site is \$2,553,854 or 2 per year for \$5,107,707 per year. Why is the proposed annual cost for channel widening IRC construction for Alternative 3 (also alternatives 4-6) 10 times higher than observed cost for per site per year?

Comment Text: 2.2. Why is channel widening proposed to cost so much even under the no-action alternative? Under the no-action alternative (p. 2-55): Existing habitat on the System combined with SWH projects have created a total of 11,832 acres, leaving 3,999 acres to be created (Table 2-13). Total 2004-2016 cost for creating SWH was \$218,112,900 assuming all site acquisition was for SWH (a generous assumption) adds an additional \$130,407,000 for a total of \$348,519,900 or 47.7% % of MRRP total expenses. This provides a liberal estimate of total expenditures to acquire and create the 11,832 acres of SWH under the no-action alternative or \$29,456 /acre of SWH. In contrast the no action alternative for the remaining 3,999 acres of SWH allocated as channel widening (3,519 acres) and backwaters (480 acres) under the DEIS Table 2-14 is \$1,836,033,033 for channel widening and an additional \$65,529,009 for backwater construction. These total \$1,901,562,042 (57.7% of total estimated cost) or \$475,509 /acre of SWH under the no-action alternative #1. How is it possible that projected cost per acre of SWH under the no-action alternative is now 16X higher than the observed cost per acre for the bulk of SWH creation?

Organization:

Commenter: Unaffiliated Individual **Page:** **Paragraph:**

Correspondence Id: 245 **Comment Id:** 644908 **Coder Name:** jgutierrez

Comment Text: One would assume that should Alt 1 be implemented annual program costs would approximate historical costs (adding a bit for inflation). This is not the case as demonstrated below: DEIS Alternative 1 (no-action) has an estimated MRRP average annual cost of \$121,513,501 (Appendix F, Table MRRP EIS Alternatives - Cost Estimates) over double that of the MRRP average annual cost from FY2004 -2016 of \$56,149,126 (Table Missouri River Recovery Program1 (MRRP) Allocations). The average annual cost for the no action alternative is higher than any maximum annual expenditure for the MRRP program

(\$85,000,000 in FY2007} over the 13 year period of record. How can a no-action alternative that is required to represent "no change" from current management direction or level of management intensity" cost over 2x that of the existing level of the no-action management intensity? Note: Comparisons of historical and DEIS cost estimates throughout these comments are generally reported comparatively (e .g. order of magnitude or percentage) rather than estimates examined in isolation as recommended by D. Ponganis, Jan 2017 MRRIC meeting, Kansas City, MO. SIGNIFICANCE OF CONCERN. A major purpose of the no-action alternative is as a comparison or reference against which to evaluate all other alternatives. Given that the no-action alternative appears to misrepresent what actions were taken in the past and grossly overestimates their costs we are left with an inability to accurately evaluate proposed alternatives including the preferred alternative. ACTIONS RECOMMENDED. Include annual expenditures for the duration of MRRP by analogous categories shown in EIS Alternatives - Cost Estimates as an addendum to Appendix F (i.e. Table Missouri River Recovery Program (MRRP) Allocations; Harburg 2017) and used in the text when comparing costs of various alternatives to the non-action alternative. This will enable the reader to compare actual expenses for the MRRP to those given for all alternatives in the DEIS. Consider revising the DEIS to include a valid no-action alt which continues the MRRP 'exactly' as it is now and reflects the USFWS definition of a 'no-action' alternative, i.e. management actions undertaken following the 2000 and 2003 BiOp RPAs and revise the budget to reflect this. All subsequent alternatives then should be compared with this current MRRP implementation 'no action' alternative - - not a misleading no-action alternative that includes millions of additional\$ and channel widening activities not a regular part of past BiOp compliance management actions. Alternatively, please explain the EIS policy implications of substituting a 'new action' alternative as the 'no action alternative'?

Comment Text: While we understand the purpose of the MRRP and the MRRMP, it is necessary for us to comment on the cost of continuing this program. We also comprehend the current requirements of the ESA and that economics and risk are not part of that Act. The DEIS does not include the actual budgetary impact of implementing any of the alternatives. Arguably, in the Corps defense, it is probably due to the fact that they are not the budget decision maker. That responsibility falls to Congress. However, the cost to implement has an environmental impact. Resources for habitat protection, land acquisition, wastewater projects, drinking water projects, stormwater projects, just to name some examples, are diverted by the expenditures for the alternatives presented in the DEIS.

Correspondence Id: 228 **Comment Id:** 645813 **Coder Name:** jgutierrez

Comment Text: Our greatest concern is not accuracy at the outset (although it must be accurate both in terms of direction and relativity). Our most pressing comment is the lack of delineation of thorough review of economic impacts throughout the adaptive management process. Detailed methodology, check points, stakeholder engagement, how impacts will be agreed upon and how they

will affect decision making must be spelled out. We are concerned there is no set aside or clear opportunity for that review or for how the outcomes of such a review would influence further management actions. We don't know what will change in the AM process and there are obviously myriads of questions swirling around the accuracy and predictability of impacts from management actions.

Organization: Coalition to Protect the Missouri River

Commenter: Dan Engemann **Page:** **Paragraph:**

Correspondence Id: 228 **Comment Id:** 645812 **Coder Name:** jgutierrez

Comment Text: The DEIS must be amended to include detailed economic and social review of the AM process. Concluding that initial predictions from truncated modeling are sufficient is wholly inadequate and can lead us to employ management actions that can have severe and lasting negative impacts on all species, including humans.

Organization: Coalition to Protect the Missouri River

Commenter: Dan Engemann **Page:** **Paragraph:**

Kept Private: No

Correspondence Id: 228 **Comment Id:** 645810 **Coder Name:** jgutierrez

Comment Text: 7. The DEIS does not specify a robust process for ongoing analysis of economic impacts of adaptive management actions. Just as adaptive management hypothesizes, tests actions and then assesses outcomes on the species, it must allow for the inclusion of economic outcomes to inform the process and inform decisions regarding changes to management actions. Adaptive management recognizes that we do not yet know what management actions are required or how those actions will impact the species. We will not argue against the logic of taking an adaptive management approach to recovery. The MRRIC process of independent scientific review has revealed that what was once represented as science was, at best, informed hypotheses. Proceeding forward with unproven theories on spawning cues, recruitment and habitat is foolish and greatly increases the potential for doing more harm than good.

Comment Text: ISAP further suggested the need for higher magnitude flows than even FWS had requested. Eleven years after the first Biological Opinion requesting modified flows from reservoirs, the ISAP, a group of nationally renowned river scientists selected by the Corps, stated: -An integrated management plan, to be effective, should include managing flows, temperature and sediment, and implementing floodplain easement purchases and restoration. Without such an approach, where all three actions are taken, the Pallid Sturgeon would likely continue to decline. -An adaptive management plan should be developed below Gavin's Point, a plan originally set as an RPA, but never implemented by the Corps; and -A need for restoration practices to prevent declines in listed and other desired species ... include providing flows higher than those currently prescribed spring pulses, lower baseflows, and increased sediment.

Comment Text: Our comments below evaluate the MRRP-EIS with these goals in mind. Where possible, we include additional factors that may be important for the species based on the current state of the science. While the two stated goals are important, the metrics outlined in this DEIS for assessing success in meeting them are insufficient. As an example, the stated goal of increasing pallid sturgeon recruitment to age 1 is too simplistic in nature to understand the mechanism behind the metric and thus insufficient to meet the goals of the Adaptive Management Plan. In this specific example, the Corps should develop sub-metrics of the overall goal to support revised management actions. Specific sub-metrics could include prey species abundance, competitor abundance, type of substrate and habitat, turbidity and other factors considered important in the conceptual models.

Comment Text: Current constraints on the volume of flows which can be used to create sandbar habitat or potentially benefit pallid sturgeon need to be addressed as part of any management alternative implemented. The current channel capacity of the Missouri River from Fort Randall Dam to Lewis and Clark Lake is 35,000 to 40,000 cfs (Table 3-2 of the MRRMP and EIS) and is obviously the main flow constraint for ESH-creating or pallid sturgeon bimodal spring pulse flow magnitude. As an example, the fall ESH-creating flows from Gavins Point Dam would involve flows of up to 60,000 cfs, with Fort Randall Dam releases being increased a similar amount. With a channel capacity of 35,000 to 40,000 cfs in this reach, flooding would occur. However, if flow limits

downstream of Gavins Point Dam are exceeded, Gavins Point release would be reduced by 5,000 cfs until flood targets are no longer exceeded. In instances where Gavins Point releases fall below 45,000 cfs, releases would be terminated. There is no mention of flows being reduced if they exceed the channel capacity and flooding occurs in the Ft. Randall to Lake Lewis and Clark reach.

Comment Text: 3. Pallid Sturgeon Population Augmentation. STATEMENT OF CONCERN. Stocking proposals for pallid sturgeon throughout the DEIS and supporting documents address only stocking 'optimal size classes and in optimal numbers'. These criteria have little relevance to fitness and survival of stocked fish to reproduction. BASIS FOR CONCERN. Despite stocking thousands of pallid sturgeon to the Lower Missouri River, few are reproducing and condition of stocked pallids is declining. Both hatchery conditions (Kittle and Small 2014, Deslauriers et al 2016, Meyer et al. 2016) and environmental factors (Steffensen and Mestl 2016, Randall et al 2016) are believed responsible. Recommendations to improve the Middle Basin Propagation Program (Basin-wide Pallid Sturgeon Propagation Committee 2016) are a step in the right direction, but the overall philosophy of sturgeon population augmentation in the DEIS is misplaced on numbers of stocked fish. SIGNIFICANCE OF CONCERN. Only three larval pallid sturgeon have been collected in the Lower Missouri River over the past decade (Middle Basin Pallid Sturgeon Work Group annual meeting, January 2017, Blue Springs, MO) despite an intensive sampling program under HAMP and PSPAP. Adult stocked pallids are routinely collected under these programs (see HAMP and PSPAP annual reports), yet few appear to be spawning (Deloney et al. 2015). Reducing jeopardy under the BiOp RPAs is highly dependent on survival and reproduction of hatchery stocked pallids. All proposed efforts of the MRRMP (and specifically Pallid Sub-Objective 2) will be in vain if healthy, reproductively mature pallid sturgeon do not spawn in sufficient numbers in the upper and lower Missouri River. RECOMMENDED ACTIONS TO RESOLVE. The overall philosophy of Pallid Sturgeon population augmentation needs to shift to a focus on quality of stocked fish over quantity. 'Quality' of stocked fish should also be identified as a potential limiting factor and addressed in the DSAMP. Quality criteria should include physiological and ecological factors such as overall health of fish when stocked, the ability of newly stocked pallids to adapt to natural river conditions (e.g., feeding, positioning in current and habitat selection) and grow and perform as well as wild fish. Actions to improve the quality of propagated and stocked pallid sturgeon so they reach sexual maturity and spawn in the wild should be identified in the Effects Analysis and SAMP. This can be achieved Under Big Question #6 Population Augmentation, components 1 and 2.

Comment Text: Volume Four of the draft MRRMP-EIS is titled "Implementation of Preferred Alternative under Adaptive Management" and contains only select components of the larger AMP. Volume 4 also labels the AMP as a "companion document" to the MRRMP-EIS. The AMP is much more than a companion document; it is integral and its full contents should be recognized and its acceptance documented by the ROD. The ROD should also acknowledge the living nature of these documents as Volume 4 does. The ability to draw readily from the other alternatives fully analyzed in this NEPA process and the entire AM Plan should not be hindered by a limited ROD.

Comment Text: While the "skinny fish" problem has been, and is being, addressed as "new information" within the Adaptive Management context, we are concerned that the Adaptive Management design does not have an "on ramp" or design specification for inclusion of new endangered species listings to occur in the future. In particular, Sturgeon Chub and Sicklefin Chub have a new petition for listing, pending review by the Fish & Wildlife Service. A hypothesis might be generated that recovery of pallid sturgeon is dependent on recovery of one or more of these fish.

Comment Text: There are multiple lines of evidence that ecosystems in various reaches continue to show stress and declines in food webs essential to the survival of pallid sturgeon. The DEIS refers to many of these lines of evidence. And, it is our hope that Adaptive Management- - as adopted in the Record of Decision and implemented- - would be aggressively adaptive enough to ascertain ecosystem signals of distress against a background noise of degraded values and constant extraction and exploitation in time to prevent further endangered species listings.

Comment Text: It is extremely unlikely that Big Questions 1 through 4 (SAMP-draft 6- Sect 4.2.4, table 43; and elsewhere) which refer to, and study, "naturalized flows" can be efficiently or definitively answered by passively monitoring existing, or historical record, Corps operated flows. Of the five hypotheses deemed, by the Corps, to meet or exceed criteria stipulated by the Effects Analysis documents for "avoiding jeopardy", only Alternative 2 aims at approximating "naturalized flows". Alternatives 4 through 6 aim at remediating interventions for the attenuation of naturally occurring flow regimes; but these interventions for attenuations caused by the dams, reservoirs and BSNP channelization are not, in and of themselves, natural. Moreover, even as some of the corollary hypotheses already benefit from Level 1 reflection on past operations data, these hypotheses become bootless and cannot be tested by falsification if they cannot ascend the stepwise decision process through levels 2, 3 and 4- - which is the implicit effect, if Alternative 3 is retained as preferred to become the selected alternative. Level 2 lab studies would have no effect on pallid sturgeons living in the river and insufficient statistical power to overcome what is, essentially, a policy decision preference for an intervention (Alt 3) that may not work.

Comment Text: While we appreciate the concept of adaptive management and the need to be flexible as conditions in the Missouri River basin change over time, the State is concerned that the adaptive management provisions laid out in the draft EIS will result in more uncertainty for landowners with respect to the impacts of water flow management and timing of pulses that may contribute to

flooding on agricultural lands. Many of the evaluated alternatives include spring or fall flow pulses that could contribute to flooding of thousands of acres of agricultural land at times when farmers are either trying to plant or harvest crops. Of particular concern are the average annual NED flood risks in the Gavins Point to Rulo reach of Alternatives 4 and 6, and the full release years impacts of Alternatives 5 and 6 in the same reach, as projected in the Flood Risk Management Environmental Consequences Analysis Technical Report. Also of concern are the Interior Drainage NED risks of Alternatives 2 and 4 as projected in the area of MRLS 575-L, some of which occur beyond the release year, as reported in the Agriculture and Interior Drainage Environmental Consequences Analysis Technical Report. If these pulse flows are components of an adaptive management strategy, we are concerned that decisions made with respect to water flow management could result in spring flooding that would prevent timely planting or fall flooding that would occur before crops are ready and able to be harvested. Furthermore, many business and agronomic decisions are made by farmers well in advance of a crop year, and impacted producers will be faced with increased risks associated with land management decisions if adequate lead time is not factored into adaptive management. Therefore, we request that any implemented alternative which incorporates adaptive management include provisions that maximize the amount of time between approving and implementing flow pulses and associated water level rises, particularly in the spring and early fall. This will give states and impacted residents and businesses appropriate opportunity to weigh in on implementation decisions and prepare for potential impacts.

Comment Text: The big questions for the Lower Missouri River appear to be focused solely on age-0 Pallid Sturgeon. The State believes this should be expanded to the full range of Pallid Sturgeon life stages and potential management actions to meet the full range of needs, as they are likely all interrelated. Providing for the requirements of Pallid Sturgeon throughout all life stages is likely the only way to provide a successful self-sustaining population. Also, consideration of other native species should be included as to avoid listings of additional species.

Comment Text: In its 2003 amendment to the 2000 BiOp the USFWS took issue with the USACE's design of its adaptive management approach. Fearing delays in implementing management actions by performing research as a surrogate for evaluating the effects of management actions, the USFWS explained what an adaptive management is supposed to be: "Adaptive Management is founded on simplicity: identify desired outcomes; take reasonable management actions that are believed to yield positive results; monitor those actions to determine if the expected results were achieved; and make management changes based on the new information." The USACE should adopt this approach to adaptive management.

Comment Text: The USFWS envisions true population monitoring as appropriate for Levels 3 and 4. Because Levels 1 and 2 represent research studies, the data collection at these levels should be integral to the specific research and will likely be completed by a wide array of entities conducting the studies. The USFWS envisions monitoring crews assist with data gathering or accomplishing tasks for Levels 1 and 2, when they overlap efficiently with Level 3 and 4 monitoring activities. Many Level 1 and 2 studies will transition to Level 3 and 4 actions. When this occurs, the pallid sturgeon monitoring program will need to be revised to address the broader implementation scale or new needs for adaptive management associated with the original question/hypotheses, the USFWS looks forward to continued engagement in this process

Comment Text: Decision trees within the Draft MRRMP EIS adaptive management plan (adaptive management plan) describe the ecological responses and knowledge acquisition considerations within the adaptive management process to move to higher levels of

action, e.g. Level 3 and Level 4. Additionally, the governance process engages the partners and stakeholders who have interest in the decision process. However, the USFWS is concerned that the numerous administrative and regulatory process requirements may slow movement within the adaptive management plan. Hence, the USFWS recommends the Corps include and describe 'action forcing' criteria to ensure appropriate changes are made in a timely matter within both the scientific and administrative portions of the adaptive management plan. The USFWS has consistently maintained that the MRRMP EIS should contemplate and evaluate the full suite of actions that the Corps can take so as to reduce the potential for further process delays during implementation of the Missouri River Recovery Program (MRRP).

Comment Text: Section & Page Number: 4.9, p. 4-33 "The MRRMP-EIS establishes an AM plan for the next 15 years (approximate) that is flexible and should allow many of the management actions specified within the Preferred Alternative to proceed without additional NEPA analysis. Information gathered through the adaptive management process will be used to adjust operations within the range of the impacts analyzed in this EIS." Comment: This statement illustrates how broad and open-ended the AMP is. As framed, it is difficult to understand what substantive limits govern the range of allowable adaptive adjustments. And, after reviewing the EIS, the limit of the Preferred Alternative itself is not clear. The actions contained in the Preferred Alternative are outlined in Section 2.10, but then that section has the following sentence regarding pallid sturgeon actions in the upper basin: "After this research and monitoring the intent is to follow the decision criteria and governance process described in Chapter 4 of the AM Plan to guide implementation of subsequent activities." Figure 4-4 (page 4-7) lists actions to be implemented within the next 15 years for the pallid sturgeon in the upper basin. The table includes actions such as "Fort Peck Flows" and "Drawdowns." Based on a review of the AMP,

it is assumed that "Drawdowns" means a drawdown of Lake Sakakawea. It is not clear if the USACE considers all of these actions as part of the Preferred Alternative. If they are part of the Preferred Alternative, it is even more unclear if the USACE considers the effects of these actions to have been evaluated in this EIS. A drawdown of Lake Sakakawea was not simulated in the hydrology and hydraulics models; however, in consideration of how this is framed in the EIS, it could be interpreted to be inherently a part of the Preferred Alternative that is proposed. The adaptive management portion of the Preferred Alternative is severely lacking in clarity and boundaries. To be clear, the State of North Dakota opposes any action outside the constraints of the current Master Manual - unless there is meaningful consultation specific to such action with the state government (apart from the MRRIC, FWCA, and AOP processes). Commenting on an EIS or other NEPA document will not satisfy the need for such direct consultation. This applies to any flow management action that could be interpreted as inherently part of the Preferred Alternative (i.e. Fort Peck flow changes, Lake Sakakawea drawdowns), any flow management action outside the Preferred Alternative but evaluated in this EIS (i.e. ESH-creating flows), and any flow management action beyond this EIS that is a result of future adaptive management.

Comment Text: Section & Page Number: 4.4.2, p. 4-7 Comment: Figure 4-4 presents AMP initial actions in the Preferred Alternative. The major area of concern and in need of clarification is Big Question 5: Passage, drift and recruitment Level 2 initial action "drift experiments, Fort Peck flows and drawdowns." North Dakota has serious concerns and lacks understanding of what if any sideboards or constraints are placed on flow modification and drawdown. The AMP does not adequately define what types of flow modification or drawdowns are under consideration. Flow modification out of Fort Peck Dam has been a topic of discussion for a long time and identified in the 2003 Amended Biological Opinion as a need.

Comment Text: Additionally, under section 5.3.1 of the draft AM Plan, it refers to the states as cooperating agencies in the Management Plan process and that all the cooperating agencies are also members of MRRIC. South Dakota formally requested to be a cooperating agency in the MRRMP development process but that request was not acted upon by the USACE, with the idea that state participation would be through MRRIC. In previous Missouri River management efforts, like the Missouri River Ecosystem Restoration Plan and the Missouri River Authorized Purpose Study, South Dakota was a cooperating agency. While South Dakota does participate in MRRIC, we desire to fulfill our role as a cooperating agency with regards to participation in the MRRMP and the AM Plan. With four of the six mainstem dams constructed on the Missouri River within the boundaries of the state of South Dakota, we certainly have a vested interest and expertise in both the recovery of the listed species and impacts to basin stakeholders that may result from management actions.

AMP1000 Governance of the Adaptive Management Program (Substantive)

Correspondence Id: 25 **Comment Id:** 626689 **Coder Name:** jgutierrez

Comment Text: At this point, I must stress its importance the Corps working with the state through the implementation of adaptive management of Missouri River Recovery Program. We have serious concerns with respect to potential changes in the Master Manual.

The EIS includes alternatives with several flow-of-management actions that would deviate from the current Master Manual. The Adaptive Management Plan adds another layer of uncertainty due to its lack of sideboards and vagueness in how the states would be involved in the decision-making process if the Master Manual were to change. For these high-consequence decisions, there needs to be an avenue for direct consultation with experts from various state agencies who understand their authorities and responsibilities, know what questions to ask, and can recognize concerns. This is necessary to ensure that the federal government complies with state regulations and does not do something that significantly, adversely impacts the states and their right to manage natural resources within their borders. In order to alleviate these concerns, there needs to be a guarantee in the Adaptive Management Plan that if any actions are proposed to occur outside the conditions of the Master Manual, the Corps will consult with states before making any substantive modifications, apart from MRRIC, Fish and Wildlife Coordination Act, and the Annual Operating Plan process. State representatives on MRRIC are striving to reach consensus on language to be included in the Adaptive Management Plan that articulates this stipulation.

Comment Text: Therefore, we ask that the language in the third paragraph under the "States" heading of section 2.3.8 "Basin states, other federal agencies, and tribal roles outside the MRRIC collaborative process" in the AM Plan be changed to that listed below:

"With regard to the regulation of the Missouri River Mainstem Reservoir System, the USACE will continue to provide a draft and final Annual Operating Plan (AOP) that describes the planned operation of the reservoir system within the conditions of the Missouri River Mainstem Reservoir System Master Water Control Manual (Master Manual) for the coming year under a variety of runoff conditions. States will have the opportunity to provide comments on the draft and final AOP at the public meetings or by providing written comments during the comment periods. If at any time during AM Plan implementation, the Basin States or USACE determine the actions proposed to occur are outside of the conditions of the Master Manual, the Corps will first consult with all the Basins States, their designated representatives and/or other interstate organizations consisting of Missouri River Basin State representatives before making any substantive modifications. Additionally, states retain the right to comment or request consultation outside of MRRIC, FWCA, and AOP processes on any issue related to the Management Plan or ongoing AM process via official letter at any time."

Comment Text: Adaptive Management Plan Comments South Dakota and other state representatives on MRRIC have been discussing the role of states in the governance process of the MRRMP with the USA CE for over two years. The Fish and Wildlife Coordination Act gives states the opportunity to provide input to the USAGE, through the USFWS, on ecological and biological considerations of management actions and alternatives to benefit the listed species. However, it does not adequately provide states the opportunity to be briefed and consult with the USAGE on implementation of management actions which will affect Missouri River stakeholders within each state. South Dakota appreciates the effort made by you and your staff General, to come to Pierre in early December of 2016 to discuss the MRRMP, EIS, and governance of the AM Plan with the Governor's staff and representatives from the departments of Environment and Natural Resources and Game, Fish and Parks. That is the type of interaction between the USAGE and the State of South Dakota that we would like referenced in the governance portion of the adaptive management plan, in association with any changes to the Master Water Control Manual.

Comment Text: As much as we complain about elected officials, they are the representatives of the people. The governors are the highest level of the peoples' interest. The governance structure reduces the States' authority to protect States' interests by not providing a platform for their "direct" involvement other than participation through MRRIC. This is unacceptable. In addition, membership in MRRIC is selected by the Corps. While we respect the current Corps leadership, a structure must be protective of the risk of the federal government choosing membership most biased to its position. For that reason alone, MRRIC cannot be presumed to represent the public interest in decisions on the management of the river. Its charter can also be revised removing key current presumptions, such as requiring unanimous consensus. For these reasons we believe the adaptive management governance is flawed and requires revision.

Comment Text: The AM Plan describes a proposed governance structure (Section 1.2.2, page 18) for decision-making where composition of the Technical Team may include Federal and state agency personnel, university professors, and contractors selected to address the underpinning science for the program. It is unclear whether state fish and game agencies would be included on the Technical Team, or serve as contractors. Actions taken under the EIS and AM Plan will affect wildlife under the jurisdiction of state fish and game agencies. Actions taken will also have an impact on recreation in basin states. However, USACE plans for engagement and state fish and game agency roles within the process remain undefined.

Comment Text: [Adaptive Management Plan (Version 6)] Section 2.3.7.3, page 97 - We strongly recommend that there be an ISAP and a Separate ISETER panel as recommended by MRRIC for the reasons stated in MRRICs recommendation. We recommend that MRRIC and the USACOE establish a rotational process for the Independent Panel. Bringing new members onto the Panel refreshes

the review and provides new insights into hypotheses of the AMP. We recommend that the Panel elect a chairperson to prepare all responses to questions posed by MRRIC/Agencies. The third party science neutral would be used to identify replacement candidates for the rotational process. An alternative process for the Independent panels is to select the members who will participate in questions from MRRIC/Agencies as selected for each review task. For example if it is strictly a science question related to pallid sturgeon, it may not be necessary for the expert economist to participate, but they would be aware by being a panel member. This section should be modified to address the two roles of the Panel, review and advisory. It is important that the Panel remain neutral which is difficult if they are directly engaged in development and implementation of the MRRP. As the AMP is implemented, while there is an advisory role for the Panel, it should be implemented in a manner to preserve the independent review capabilities of the pane as much as possible. This is different than has occurred through the development of the AMP in which the Panel has been used in many cases as an advisory group.

Comment Text: In the draft Adaptive Management Plan, the State is concerned about the lack of a defined role for state fish and wildlife agencies. The General Engagement Process for Science and Development of the Work Plan does not depict a role for state fish and wildlife agencies. It is unclear how these entities would fit into the process, although they are responsible and have jurisdictional authority for fish and wildlife in their respective states. Similarly, while the statutory role of state fish and wildlife

agencies is acknowledged in section 2.3.8.1, the proposed governance structure described in Adaptive Management Plan documents and Section 4.6 appear developed in large part for collaboration with the Missouri River Recovery Implementation Committee (MRRIC), and does not seem to cover duties assigned to state fish and wildlife agencies. The role of state fish and wildlife agencies in decision making could be better defined.

Comment Text: Under the Fish and Wildlife Coordination Act (FWCA), FWP is provided with a framework to have fish and wildlife conservation measures considered for incorporation into federal water development projects; however, this opportunity is unavailable to other state agencies (e.g., DNRC). The State supports efforts to broaden the opportunity for input outside of the FWCA and outside of the Missouri River Recovery Implementation Committee (MRRIC) to ensure the State's perspective is fully considered. As such, the State of Montana, in collaboration with other Missouri River Basin state government agencies, _developed the following suggested replacement language for the section pertaining to the roles that basin states, other federal agencies, and tribes would be afforded outside of the MRRIC collaborative process (p. 103, sec. 2.3.8.1, SAMP, MRRMP-EIS): Each state has responsibilities through various federal and state statutory and constitutional authorities, for management of water quantity, water quality, and fish and wildlife resources within their boundaries that could be affected in this process (in either a positive or negative way). As previously stated this governance structure does not change or impede any of the rights and responsibilities of a state codified by law.

AMP1100 Decision Needs to Adaptively Manage the MRRP (Substantive)

Correspondence Id: 134 **Comment Id:** 640684 **Coder Name:** jgutierrez

Comment Text: The proposed AMP needs a much stronger stop doing function as part of its structure. The description on page 12 of the Draft Adaptive Management Plan suggests that a theory may be discarded after implementation, monitoring and evaluation show it is not workable. However, the primary path seems to be for the advocates to propose variations to their theory and additional research to see if the revised theory works any better. A weak stop doing function provides an endless do loop for theories early and stifles innovation by preventing other theories from being considered due to limited research resources. The stop doing element of the AMP needs to be strengthened considerably to quickly eliminate theories that lack quantitative scientific support in order to make room to test other theories.

Correspondence Id: 236 **Comment Id:** 645779 **Coder Name:** jgutierrez

Comment Text: More emphasis should be placed on ensuring available empirical information is utilized in the process of evaluating hypotheses and developing alternatives for management and implementation. Working with the State to utilize our expertise and local knowledge of the connected Missouri River Yellowstone River ecosystem would substantially improve the effectiveness of recovery actions and would be far more cost-effective. The Science and Adaptive Management Plan (SAMP) was developed to " ... address the uncertainty associated with potential Pallid Sturgeon limiting factors," (p. 1-17, sec. 1.3.1 , Volume 1, MRRMP-EIS). Unfortunately, the document arbitrarily ignores uncertainties associated with attaining successful two-way fish-passage at the Intake Diversion Dam (a structure not operated by the USACE) while postponing needed improvements to Fort Peck Dam operations that are inexplicably deemed infeasible. The predecisional opposition to modify discharge or correct thermal pollution at Fort Peck Dam is surprising, given that the 2003 Biological Opinion (BiOp) clearly states, "In the Upper Missouri River, continued operation of Fort Peck Dam as proposed will continue to significantly impair the reproduction and recruitment of Pallid Sturgeon in this reach. These factors affect the production of forage fish which are important to the overall survival of Pallid Sturgeon," (p. 179, 2003 Amendment to the 2000 BiOp). Selective withdrawal devices are operational at other USACE-operated projects, including Libby Dam in western Montana, and their implementation has greatly benefited the federally-listed Bull Trout and other native fishes. Addressing Pallid Sturgeon limiting factors objectively (e.g., in parallel approach) in the connected Missouri River Yellowstone River ecosystem would serve to more effectively avoid jeopardy to Pallid Sturgeon and would exemplify the" ... demonstrated need to develop a management plan comprised of actions informed by best available science," (p. 1-17, sec. 1.3.1, Volume 1, MRRMP-EIS). As such, the State recommends that the MRRMP-EIS address the Missouri and Yellowstone rivers as connected Pallid Sturgeon habitat and work in parallel to develop alternatives for management and implementation. Specifically, the State requests that efforts to improve Fort Peck Dam operations for the benefit of Pallid Sturgeon and the downstream Missouri River ecosystem not be conditioned on the success of Pallid Sturgeon passage at Intake Diversion Dam in the MRRMP-EIS.

Comment Text: The AMP (AMP 2-page 469) says that major events, such as floods, are occasionally the subject of post-event investigations that can be used to update information on the effects of flows on HCs. We applaud this step but would also ask that major droughts be considered a major event. The historic hydrograph shows many more years of below average runoff in the upper basin than above average. When President Roosevelt signed the 1944 Flood Control Act, he wondered where the water to support the

purposes would come from, given the upper basin is semi-arid. Prolonged drought conditions are a concern of the League and we think it will become an even greater concern as more and more users extract water from the reservoir system.

Comment Text: Decision Criteria for some targets are described in the Adaptive Management Plan, while others are yet to be developed. While the AM Plan focuses hypotheses on three listed species, including addressing pallid sturgeon decline and the recruitment bottleneck from Age-0 to Age-1, ecosystem function could be more thoroughly considered. The 2000/2003 Biological Opinion identified alteration of big river ecologic functions and habitat as a primary cause of declines in reproduction, growth, and survival of pallid sturgeon (page 104). A number of additional species are known to be in decline in the Missouri River currently, including species petitioned for listing in August 2016 which are part of the pallid sturgeon diet. As proposed in the AM Plan, new information would be integrated into hypotheses, including underlying causes of pallid sturgeon in poor body condition documented by Nebraska Game and Parks Commission (January 2016, page 292 of the AM Plan). Later work that year by R. Jacobson confirmed declines in fish condition in the lower Missouri River basin.

Comment Text: The proposed AMP needs a much stronger stop doing function as part of its structure. The description on page 12 of the Draft Adaptive Management Plan suggests that a theory may be discarded after implementation, monitoring and evaluation show it is not workable. However, the primary path seems to be for the advocates to propose variations to their theory and additional research to see if the revised theory works any better. A weak stop doing function provides an endless redo loop for theories early and stifles innovation by preventing other theories from being considered due to limited research resources. The stop doing element of the AMP needs to be strengthened considerably to quickly eliminate theories that lack quantitative scientific support in order to make room to test other theories.

Comment Text: The DEIS gives the Corps unchecked authority by permitting a broad application of adaptive management that goes beyond the authority established by other previous AM Plans. Though the DEIS states there is a governance structure for the AM Plan, it simultaneously permits actions that are not part of the preferred alternative, if those options are warranted and feasible. Yet, the DEIS fails to clarify what constitutes warranted and feasible, beyond that which yet-unknown science deems necessary. As a result, the DEIS and the AM Plan open the door to actions that go beyond the established ROD without automatically triggering a full NEPA process to produce a supplemental EIS, as is required by law.

Comment Text: Section 4.0 Adaptive Management Plan General Analysis: 1. By definition and design, adaptive management (AM) means the management actions are not yet identified. We can only speculate on the direction of impacts because we only know the direction of management actions. It is impossible to provide the appropriate quality and scope of comments on management actions when not even the Corps or the FWS knows what actions they will take. AM plan decisions made outside of the ROD and Master Manual must go through full NEPA review and a separate EIS and must include independent peer review of the science and be coupled with full public review and comment before finalized. 2. The Corps should communicate what actions they believe to be implementable under AM. If stakeholders are to participate in a meaningful way, no decisions should be made in a vacuum or come as a surprise. 3. The Corps should commit to the use of two independent panels in AM plan independent review. We believe socio-economic impact review and analysis to be a key part of AM and it should continue to be utilized. As weve pointed out, the DEIS modeling and assessment of human impacts is woefully inadequate, highlighting the important need for review by both panels.

Comment Text: Most of all were concerned over the lack of provisions for actual measurement, how it will be conducted and how it will inform the AM decision making process. It must be spelled out and be an integral part of the AM process. The AM process cannot be limited to adapting management actions for just one species. We should not be so cautious as to avoid experimentation and application of successful actions, nor so arrogant as to believe simple modeling accurately reflects economic impact.

Comment Text: The Adaptive Management (AM) Plan envisions a rigorous science program. If executed properly, meaningful steps can be made towards understanding species needs while minimizing impacts to the human environment and other uses. The Corps and the FWS must focus on further developing the science necessary to understand what is needed for species survival. For example, rather than committing the vast majority of budgetary resources to habitat construction, the Corps should also emphasize research and monitoring to understand the species habitat needs. Furthermore, the feedback loop of the adaptive management process was largely forgotten in the years following the 2003 Bi Op. During that time hundreds of millions of dollars were spent on the Missouri River Recovery Program and very little time and focus was spent on learning from the research and monitoring. It is extremely important that this is changed.

Comment Text: While we appreciate the concept of adaptive management and the need to be flexible as conditions in the Missouri River basin change over time, the State is concerned that the adaptive management provisions laid out in the draft EIS will result in more uncertainty for landowners with respect to the impacts of water flow management and timing of pulses that may contribute to

flooding on agricultural lands. Many of the evaluated alternatives include spring or fall flow pulses that could contribute to flooding of thousands of acres of agricultural land at times when farmers are either trying to plant or harvest crops. Of particular concern are the average annual NED flood risks in the Gavins Point to Rulo reach of Alternatives 4 and 6, and the full release years impacts of Alternatives 5 and 6 in the same reach, as projected in the Flood Risk Management Environmental Consequences Analysis Technical Report. Also of concern are the Interior Drainage NED risks of Alternatives 2 and 4 as projected in the area of MRLS 575-L, some of which occur beyond the release year, as reported in the Agriculture and Interior Drainage Environmental Consequences Analysis Technical Report. If these pulse flows are components of an adaptive management strategy, we are concerned that decisions made with respect to water flow management could result in spring flooding that would prevent timely planting or fall flooding that would occur before crops are ready and able to be harvested. Furthermore, many business and agronomic decisions are made by farmers well in advance of a crop year, and impacted producers will be faced with increased risks associated with land management decisions if adequate lead time is not factored into adaptive management. Therefore, we request that any implemented alternative which incorporates adaptive management include provisions that maximize the amount of time between approving and implementing flow pulses and associated water level rises, particularly in the spring and early fall. This will give states and impacted residents and businesses appropriate opportunity to weigh in on implementation decisions and prepare for potential impacts.

Comment Text: Decision trees within the Draft MRRMP EIS adaptive management plan (adaptive management plan) describe the ecological responses and knowledge acquisition considerations within the adaptive management process to move to higher levels of action, e.g. Level 3 and Level 4. Additionally, the governance process engages the partners and stakeholders who have interest in the decision process. However, the USFWS is concerned that the numerous administrative and regulatory process requirements may slow movement within the adaptive management plan. Hence, the USFWS recommends the Corps include and describe 'action forcing' criteria to ensure appropriate changes are made in a timely matter within both the scientific and administrative portions of the adaptive management plan. The USFWS has consistently maintained that the MRRMP EIS should contemplate and evaluate the full suite of actions that the Corps can take so as to reduce the potential for further process delays during implementation of the Missouri River Recovery Program (MRRP).

Comment Text: The Nebraska Game and Parks Commission believes that the habitat goal of 20 to 30 acres of aquatic habitat per mile remains the most fundamental critical need of Pallid Sturgeon and the native fish community upon which they depend. We do believe that this effort could be improved by targeting specific habitat needs for both Pallid Sturgeon and the native fish community that they depend upon. Interception habitat should be described and quantified to determine if there is an adequate amount available throughout the river, not just below Kansas City. Rearing and feeding habitats for all life stages of Pallid sturgeon should also be described and quantified throughout the river to guide restoration efforts where they are most needed. These same efforts should be carried out for native fish species critical to the life history of Pallid Sturgeon and to the overall health of the Missouri River ecosystem. The Nebraska Game and Parks Commission strongly believes that much of the main channel habitat work, specifically those bends that had dike notching and removal, to increase top width and create shallow water habitat actually have less shallow water habitat in their in-completed state than they had prior to modification. Because these actions have occurred on nearly 40% of the bends in the channelized reach in Nebraska, if these shallow water habitats projected remained uncompleted, we would be in much worse shape than if this work had never been started.

Comment Text: The AMP (AMP 2-page 382) also mentions that post-construction monitoring of Intake would need to continue until results indicate whether or not the project has resulted in successful recruitment. The final EIS must address how long monitoring would continue before AM is implemented to make the needed adjustments to assure the project becomes successful for pallid recruitment.

Organization: The Izaak Walton League of America

Commenter: Paul Lepisto **Page:** **Paragraph:**

Kept Private: No

Correspondence Id: 177 **Comment Id:** 644650 **Coder Name:** jgutierrez

Comment Text: The AM Plan describes three levels of monitoring. At least two of the three types would occur over many years before a change in the population could be detected. While awaiting monitoring results before implementing an action, inaction could result in a continued decline in pallid sturgeon. Appendix D describes the current Pallid Sturgeon Population Assessment Program (PSPAP) objectives, sampling design and protocols were developed by an interagency team of Missouri River Basin experts (i.e., state fish and wildlife agencies) and guided by the USACE Project Delivery Team. By contrast, the proposed objectives, sampling design and protocols appear in development by the USACE and a group of scientists outside of the state agencies. Recently, a workshop was held to explain to state agency representatives the PSPAP that was recently developed. Also in that Appendix, the current proposed PSPAP sampling would seek only larval (non-drifting) pallid sturgeon below Kansas City. Drifting free embryos have been captured upstream of the Platte River. The recommendation to only sample below Kansas City for larval sturgeon is based on flow models that have not yet been validated.

Comment Text: It is stated that the Pallid Sturgeon Population Assessment Program will be continued in some form; however, there are no specifics given about what activities (e.g. inventory, monitoring, or research studies) will continue and at what level. The EIS should elaborate upon existing inventory, monitoring, and research that is underway and/or planned in the future - - this may include existing science actions in the Missouri River Recovery 2017-18 annual work plans. The current level of monitoring (including fish community monitoring) should be continued and made more robust to give the most complete picture of what is occurring in the river and how the sturgeon is affected.

Comment Text: The USFWS envisions true population monitoring as appropriate for Levels 3 and 4. Because Levels 1 and 2 represent research studies, the data collection at these levels should be integral to the specific research and will likely be completed by a wide array of entities conducting the studies. The USFWS envisions monitoring crews assist with data gathering or accomplishing tasks for Levels 1 and 2, when they overlap efficiently with Level 3 and 4 monitoring activities. Many Level 1 and 2 studies will transition to Level 3 and 4 actions. When this occurs, the pallid sturgeon monitoring program will need to be revised to address the broader implementation scale or new needs for adaptive management associated with the original question/hypotheses, the USFWS looks forward to continued engagement in this process

AMP3100 Pallid Sturgeon Evaluation (Substantive)

Correspondence Id: 131 **Comment Id:** 640136 **Coder Name:** jgutierrez

Comment Text: The Corps admits many unknowns in the life cycle of the pallid sturgeon. The recent phenomenon of skinny fish is one of those yet unexplained parts. Is part of the channelized Missouri river a food desert for the sturgeon? Is competition with native or invasive species a factor? Is lack of sediment reducing sturgeon's ability to catch prey? Is there another water quality issue? We may eventually learn details of these problematic dynamics, but we can be sure part of their resolution will be to recreate a more natural Missouri River.

Comment Text: Another concern we have in the AMP in regards to pallids is in AMP 2-page 436. "This could mean that additional engineered spawning habitat needs to be in place (see section 4.2.6.5), but presently available spawning sites may suffice to address behavioral metrics." This is a great concern for the League. Available sites cannot "suffice" when there has been very little spawning activity and virtually no documented spawning or recruitment success. We feel enhanced or restored spawning habitat must be in place for pallids prior to any flow test to adequately address if the flow and habitat is sufficient for the pallids.

Comment Text: Table 2-5 refers to the fitness of adult pallids. We believe this needs much closer examination. The existing population in both the upper and lower river must be healthy in order to have a chance to reproduce and expand recruitment. The data provided to the Corps from the Nebraska Game and Parks Commission in 2015 revealed some alarming findings on the condition of adult pallids in the lower river. We urge more research be done to find the cause and help identify what can be done to increase the health and productivity of these fish.

Comment Text: The AMP (AMP 2-page 375) states that without successful passage at Intake, a transplant experiment could be conducted. This would entail capturing pallids below Intake and hauling them above the diversion to be released. We have concerns that this will likely place high stress levels on the fish and could possibly lead to the loss of individuals in a population that is already teetering on the edge of extinction. Please provide more information about this in the final EIS.

Comment Text: Alternative 3 also includes Early Life Stage Habitat Construction or Interception Rearing Complexes (IRC) proposed for 12 sites in the first 6-7 years. This would include monitoring of these shallow water habitat sites. The League urges much more communication on IRCs with the Missouri River Recovery Implementation Committee (MRRIC), as well as the general public. Very little information and communication on IRCs has been done thus far. This concept has promise for pallid sturgeon recruitment, provided that adequate drift distance for free embryos exists. We would like to see more on the IRC concept and believe it needs much more communication and collaboration with MRRIC and the public.

Comment Text: Management actions should be designed to support native prey species. Tributaries and side channels in the Missouri River watershed provide some of the best natural flows, water temperature regulation, and water quality regulation in the basin.⁴⁰ Of 85 species studied in the basin, 77 spawn in tributaries of the Missouri River, while 25 spawn in tributaries or the mainstem.⁴¹ These habitats serve as refugia for juvenile fish and provide water quality benefits such as warm water, turbidity, and preferred substrate.⁴² Sediment input from these tributaries, now lacking due to dam construction, is important to fisheries and in providing sediment to develop or augment sandbars and in-channel islands.⁴³ ⁴⁴ Essentially, without tributary habitat, the prey species the pallid sturgeon depends on would disappear. A holistic watershed-based approach should quantify the habitat needs of important prey species as well as the pallid sturgeon and develop management actions to enhance habitat for the most important prey species.

Comment Text: The Corps should also provide a decision tree highlighting the future changes in operations that could occur if the spawning cue releases are shown to benefit pallid sturgeon recovery. -The above proposed changes in reservoir releases to support spawning cues is the outcome from the best-case scenario. The Corps notes in the EIS that these spawning cue releases would not be started or would be terminated whenever downstream flow limits are exceeded. For instance, the Corps states in the EIS that they would initiate a March pulse once navigation releases were met at downstream target locations. The peak Gavins Point release would be two times the navigation release on the pulse initiation day. Further the Corps states that "When conditions and rules allow, pallid sturgeon spring flow releases under Alternative 2 would consist of two pulses of water released in spring from Gavins Point Dam-one pulse in March and a second pulse in May. If both pulses meet their flow design specifications, a low summer flow would be initiated." These conditional statements provide a level of uncertainty not supported by the Biological Opinion. - The Corps should conduct a scenario analysis, develop decision criteria and performance metrics to communicate the likelihood the proposed flow modifications will occur given the conditional statements cited above. The need for this was highlighted in the Adaptive Management Plan, which stated, "At present, there are no programmatic-level triggers for the introduction of new management actions."

Comment Text: Our comments below evaluate the MRRP-EIS with these goals in mind. Where possible, we include additional factors that may be important for the species based on the current state of the science. While the two stated goals are important, the metrics outlined in this DEIS for assessing success in meeting them are insufficient. As an example, the stated goal of increasing pallid sturgeon recruitment to age 1 is too simplistic in nature to understand the mechanism behind the metric and thus insufficient to meet the goals of the Adaptive Management Plan. In this specific example, the Corps should develop sub-metrics of the overall goal to support revised management actions. Specific sub-metrics could include prey species abundance, competitor abundance, type of substrate and habitat, turbidity and other factors considered important in the conceptual models.

Comment Text: The one-time spawning cue test: From a scientific point of view, a one-time test is virtually worthless, certainly it is not adequate for data quantity. There needs to be enough repeat of the testing in order to rule out variability and background noise, and to have a minimal data points at least to have some kind of statistical analysis. Using natural rises in data gathering is great, but data collection will be a challenge. The time span of 10 years before a release would be conducted is simply a caving-in to the anti-spring rise, anti-release interests - plain and simple. It is accommodating the very vocal ag and levee districts. The wild pallid sturgeon population is aging and there really isnt time for a ten year delay before a scientifically designed release can be studied.

Comment Text: Plans for development of spawning habitat and interception rearing complexes (IRC) for larval pallid sturgeon as outlined in Alternative 3 should be implemented. Expanding the budget for Level 1 and 2 research on the effectiveness of physical habitat creation and modification within the current river channel needs to be a priority. However, if research indicates these habitats are contributing to reproduction and recruitment of pallid sturgeon, we recommend the goal of 20 acres of shallow water habitat or IRC per river mile be increased to 30 acres per river mile, the upper end of the range specified in the 2003 Amended Biological Opinion. An additional justification for an increase in effort on Level 1 and Level 2 studies in the years immediately following plan implementation is the requirement that if Level 1 studies during the first 9-10 years do not provide a clear answer on whether a

spawning cue is important, a one-time, bimodal spawning cue test release from Gavins Point Dam, as outlined for Alternative 6, be conducted. South Dakota recommends the research effort be increased such that in 9-10 years, there is sufficient information to determine if flow modifications to annual operations of the system are needed to support pallid sturgeon recovery.

Comment Text: What is the evidence supporting this management action and the high estimated cost to create it? What other management actions were considered to benefit survival of age-0 pallid sturgeon? There is only a single statement in Vol 2 of the DEIS identifying benefits of channel widening for pallid sturgeon recruitment: P 89. L7-9 (also on P88 L9-10 of DSAMP appendices). Under Alternatives 3-6, construction of habitat to support early life history requirements of pallid sturgeon would occur following the /RC (interception and rearing complexes) concept. Best available science indicates that future acreage required to construct IRCs would most likely be achieved through channel widening. One expects this 'best available' science' would be described in the pallid sturgeon effects analysis volumes. However, in Jacobson et al 2015 (P26) there is only a single reference to channel widening as an action to benefit pallid sturgeon and it is unsupportive or equivocal as to the benefits of SWH - including channel widening: The report from the assessment (Schapaugh and others, 2010) cited the HAMP as an excellent design to achieve active adaptive management; however, the report also documented that assumptions underlying the BACJ designs were not being met under real-world conditions, and, therefore, the ability to detect effects of SWH was limited. In particular, the authors reported that the actions of dike notching and channel widening did not result in detectable changes in the fish community. Moreover there is not a single reference to observed or proposed benefits of channel widening in the Pallid Sturgeon Effects Analysis Integrative Report (Jacobson et al 2016) or as part of any working hypothesis linking management of the Missouri River to pallid sturgeon population dynamics (Jacobson et al 2016b). There are two references to channel widening in the DSAMP (P43, L 23; Table 47, P376) - but both just describe implementing the management action, not its anticipated benefits. Numerous references to channel widening are in the DAMP appendices, but again, all but the aforementioned statement that best available science supports channel widening, are details of acreages, locations and implementation processes.

Comment Text: It is extremely unlikely that Big Questions 1 through 4 (SAMP-draft 6- Sect 4.2.4, table 43; and elsewhere) which refer to, and study, "naturalized flows" can be efficiently or definitively answered by passively monitoring existing, or historical record, Corps operated flows. Of the five hypotheses deemed, by the Corps, to meet or exceed criteria stipulated by the Effects Analysis documents for "avoiding jeopardy", only Alternative 2 aims at approximating "naturalized flows". Alternatives 4 through 6 aim at remediating interventions for the attenuation of naturally occurring flow regimes; but these interventions for attenuations caused by the dams, reservoirs and BSNP channelization are not, in and of themselves, natural. Moreover, even as some of the corollary hypotheses already benefit from Level 1 reflection on past operations data, these hypotheses become bootless and cannot be tested by falsification if they cannot ascend the stepwise decision process through levels 2, 3 and 4- - which is the implicit effect, if Alternative 3 is retained as preferred to become the selected alternative. Level 2 lab studies would have no effect on pallid sturgeons living in the river and insufficient statistical power to overcome what is, essentially, a policy decision preference for an intervention (Alt 3) that may not work.

Comment Text: Comment 1: The following statement on page 25 (32/40) in Development of Working Hypotheses - Pallid Sturgeon is inaccurate for the Upper Basin Recovery Priority Management Areas (RPMAs): "However, it should be noted that despite the large and increasing knowledge base on pallid sturgeon reproductive ecology, research has yet to prove one or more critical processes that are responsible for lack of population growth." Work by Braaten, Delonay, Guy, Bramblett and others and the age structure of extant wild adult pallid sturgeon in Montana yields the conclusion that lack of population growth in the Upper Basin is caused by a total lack

of natural recruitment and, further, entrainment of drifting free embryos into toxic headwater habitats is the cause of this lack of natural recruitment. To continue to ignore this fact is unreasonable.

Comment Text: Throughout this entire report, there is a lot of focus on age-0 Pallid Sturgeon and the specific management actions (e.g., spawning cues, food and forage, spawning habitat temperature manipulation, etc.) that may help increase recruitment to age-1. We believe there should be a summary of how all of these factors are likely interrelated and how accomplishing only one or a few of these actions may not result in sought after results due to the specific needs of fishes at different life stages. Focusing on only young of year Pallid Sturgeon is narrowly focused because recent evidence from Steffensen and Mestl (2016) determined adult Pallid Sturgeon body condition has decreased in the Lower Missouri River. These body condition decreases have the potential to lead to changes in periodicity of spawning, spawning success, and egg/larvae survival.

Comment Text: 3. Pallid Sturgeon Population Augmentation. STATEMENT OF CONCERN. Stocking proposals for pallid sturgeon throughout the DEIS and supporting documents address only stocking 'optimal size classes and in optimal numbers'. These criteria have little relevance to fitness and survival of stocked fish to reproduction. BASIS FOR CONCERN. Despite stocking thousands of pallid sturgeon to the Lower Missouri River, few are reproducing and condition of stocked pallids is declining. Both hatchery conditions (Kittle and Small 2014, Deslauriers et al 2016, Meyer et al. 2016) and environmental factors (Steffensen and Mestl 2016, Randall et al 2016) are believed responsible. Recommendations to improve the Middle Basin Propagation Program (Basin-wide Pallid Sturgeon Propagation Committee 2016) are a step in the right direction, but the overall philosophy of sturgeon population augmentation in the DEIS is misplaced on numbers of stocked fish. SIGNIFICANCE OF CONCERN. Only three larval pallid sturgeon have been collected in the Lower Missouri River over the past decade (Middle Basin Pallid Sturgeon Work Group annual meeting, January 2017, Blue Springs, MO) despite an intensive sampling program under HAMP and PSPAP. Adult stocked pallids are routinely collected under these programs (see HAMP and PSPAP annual reports), yet few appear to be spawning (Deloney et al. 2015). Reducing jeopardy under the BiOp RPAs is highly dependent on survival and reproduction of hatchery stocked pallids. All proposed efforts of the MRRMP (and specifically Pallid Sub-Objective 2) will be in vain if healthy, reproductively mature pallid sturgeon do not spawn in sufficient numbers in the upper and lower Missouri River. RECOMMENDED ACTIONS TO RESOLVE. The overall philosophy of Pallid Sturgeon population augmentation needs to shift to a focus on quality of stocked fish over quantity. 'Quality' of stocked fish should also be identified as a potential limiting factor and addressed in the DSAMP. Quality criteria should include physiological and ecological factors such as overall health of fish when stocked, the ability of newly stocked pallids to adapt to natural river conditions (e.g., feeding, positioning in current and habitat selection) and grow and perform as well as wild fish. Actions to improve the quality of propagated and stocked pallid sturgeon so they reach sexual maturity and spawn in the wild should be identified in the Effects Analysis and SAMP. This can be achieved Under Big Question #6 Population Augmentation, components 1 and 2.

Comment Text: All determinations for inclusion of the six alternatives were made by USACE as was the designation of Alternative Three as the Preferred Alternative in the draft MRRMP-EIS. TNC does not find the use of "collaboration" or "ProACT process" or "ProACT discussions" accurate in describing alternative development involving MRRIC. As Section 1.2 states "USACE and USFWS collaboratively have tailored the generic ProACT approach to meet the needs of this MRRMP-EIS planning process." USACE and USFWS may have applied an approach fully internally, just not with MRRIC.

Comment Text: B. The Corps Should Produce a New Biological Assessment Before Selecting a Preferred Alternative. The ESA requires agencies to reinitiate formal consultation when "new information reveals effects of the action that may affect listed species or critical habitat in a manner or to an extent not previously considered."115 The Corps cannot rely on a patchwork of scientific data far-removed from the consultation process because "[i]t is well settled that a previous agency determination in a Biological Opinion cannot be amended or supplemented with post-determination analysis or evidence without reinitiating the consultation process."116 In the "Need for the Plan" section of the EIS, the Corps stresses the substantial amount of scientific data that has been generated on the species since the 2003 BiOp, including effects analyses for all three species produced between 2014 and 2016. 117 The Corps recognizes that the "emergence of this new information created a need for its evaluation an integration into USA CE management actions on the Missouri River for the listed species and the associated AM Plan." 118 The Corps' management actions would be better informed by synthesizing this information through the production of a new biological assessment for submission to the USFWS prior to a full EIS. This would help ensure use of the best scientific information available.119 Indeed, the acquisition of significant data shortly before the issuance of the 2000 BiOp appears to have motivated the production of the 2003 Biological Assessment: The 2003 Biological Assessment was provided because of new information concerning the effects of USACE actions that had previously not been considered and because USACE believed certain components of the RPA did not comport with the regulatory criteria for an RPA (USACE 2003a). Additionally, critical habitat had been designated for the piping plover, new information on the mortality of interior least terns and piping plovers was available, and an updated hydrology and hydraulics analysis indicated that some flow modifications could erode more emergent sandbar habitat than they would create. 120 Yet nowhere in the MRRMP-EIS does the Corps explain why thirteen years of data-collection since the 2003 Bi Op does not create a clear impetus for a new biological assessment. Rather than conduct a new round of formal consultation in uniformity with Section 7, the Corps jumps immediately to the analysis of alternatives through the MRRMP-EIS, and an updated biological assessment is rendered an afterthought: After the public comment period, the MRRMP-EIS and its supporting technical analyses and reports will serve as an information base for a Biological Assessment (BA) to be prepared by the USACE and a subsequent Bi Op to be prepared by the USFWS. The actions described in the BiOp will be reflected in the final MRRMP-EIS and ROD. 121

Comment Text: On Page 15, last paragraph, and Page 16, Table 6. NRCS Comment: The amount of irrigation water shown on Table 6 appears to be the net amount applied to the field. The gross amount pumped from the river is not shown or discussed. The difference between the gross and net amounts of water would include loss in conveyance, wind drift, evaporation, deep percolation, and runoff. In addition, water is not applied evenly across the field. The total amount of water pumped from the river would be greater than the amount applied to the field. It is not clear that the USACE analysis accounts for this difference. WATER SUPPLY ENVIRONMENTAL CONSEQUENCES ANALYSIS TECHNICAL REPORT Page 8 - the second to last paragraph, states: "The modeling results show that 33 of the 55 intakes would experience on average 57.1 days when water surface elevations would fall below operating thresholds. In addition, 21 of the 55 intakes would experience on average 14.7 days when water surface elevations are below shut-down elevations under Alternative 1. These impacts are occurring in both the upper and lower river and along riverine areas, as well as reservoirs though the reasons for these effects vary by location." NRCS Comment: The 57.1 days referenced here is not clear. Is this over the period of record, per year, or in dry years? This average number of days is also referenced on pages 14, 20, 22, 27, and 32. Thank you for the opportunity to comment. If you have any questions, please contact David Heffington, Ecologist, NRCS/USACE National Partnership Liaison, NRCS National Water Management Center (David.heffington@ar.usda.gov), or Verlon Barnes, NRCS Missouri River Basin Coordinator, (Verlon.barnes@wdc.usda.gov) . Comment Text: The following comments are provided by the USDA Natural Resources Conservation Service (NRCS) regarding the USACE Draft Missouri River Recovery Management Plan-EIS. The NRCS is supportive of USACE and USFWS efforts to improve conditions for the endangered Pallid Sturgeon, Piping Plover, Least Tern, and overall habitat restoration efforts in and along the Missouri River. Under federal conservation programs authorized by the Farm Bill, NRCS has worked with private landowners to restore wetland habitats and protect floodplains in areas immediately adjacent to the Missouri River in the area covered by the subject recovery plan. Various types of easements have been put in place, many of them perpetual, to meet specific congressionally authorized program purposes. Locations of properties with these conservation easements can be found at the following web page: <http://conservationeasement.us/> and/or by contacting the appropriate NRCS State Office. The various alternative habitat improvement activities proposed (including, but not limited to: Shallow Water Habitat, Top-Width Widening, Interception Rearing Complex, Emergent Sandbar Habitat, channel reconfiguration, Flow Management, and Land Management activities) have the potential to impact lands that have NRCS easements in place. Pursuant to 7 CFR 1468.6, USACE must obtain prior authorization from NRCS for any activities that will impact NRCS easement lands. Where a Compatible Use Authorization cannot be granted, USACE must replace the impacted easement area using NRCS' existing easement administration action procedures to exchange for replacement acres. Replacement acres must be solely under administrative control of NRCS. NRCS also offers the following specific comments on the Technical Reports noted below (pages listed are from the page numbers in the document): IRRIGATION ENVIRONMENTAL CONSEQUENCES ANALYSIS TECHNICAL REPORT On Page 9, first full paragraph, starting with "Counties..." in the last sentence the text states: "For example, Dewey County in South Dakota would experience an increase of 323 days when water surface elevations would fall below minimum operating requirements from 1942 to 2012 under Alternative 6, which resulted in this county being selected for further analysis." NRCS Comment: These 323 days do not have a basis in time, so it is not clear what the effect would be. Is this 323/70 years= 4.6 days per year below the minimum operating requirements? This could be explained in days per year, maximum or minimum days, or percent change in operation.

Comment Text: First being an engineer myself let me complement you in burying the actual data in a compendium of meaningless to me reports. Makes it hard to find real data. First Question is what is the impact inf the Pallid Sturgeon, Least tern and Piping Plover went away like dinosaurs? Secondly since that question has not been answered what is the economic impact of your alternatives? I for one can answer part of that question. Back in 2011 e=when you opened the dams and let water flow all summer we as a levee district

went out bought a pump, a tractor to run it raised our levees to avoid a flood and we lucky to save most of our crops. But as a result we ended up spending about \$100,000 dollars to protect ourselves. That has amounted to about \$50/ acre of land protected. If you do dangerous releases then we have used 1/2 of our average annual income to protect our land. By the way that income includes no return on investment it assumes the land has been paid for. Fortunately in 2011 farm prices were up so we could "afford it" (crop prices allowed the Income to be closer to \$300/Acre then. However since that time our fortunes have dimmed and we may be lucky to maintain our \$100 / acre average. Those farmers that own money for the \$5000 /acre land are not likely to survive. We have also noticed that you pull back on DIke maintenance has thrown the river dangerously close to our levees and caused sever erosion. Strange that the Corp can cause major erosion with no consequences whereas as a landowner I can't even use a tracked vehicle to clean out a drainage ditch (now designated a stream) All the above stated, I think the best alternatives are Alternate 3 (No Spring Rise) or alternative 5 (Fall Rise). A fall rise is unlikely to have a large economic impact on us because not much wheat is planted in the river bottoms and No Spring rise gets back to the rationale for funding the dams for flood control. AS a country we need to have a strong economy or we will not be in a position to protect even our most important resorces- the people.

Comment Text: The Drainage District has worked very hard, to the burden of the tax payers within the district, since 2011 in an effort to restore and repair the levee system that was damaged in 2011. Currently the data states that the levees would be able to withstand a rise to twenty-seven (27) feet. However, there is no question that extended flooding at that level would compromise the integrity of the recently repaired levees. Once again, forcing unnecessary burdens and risks on the people living and farming within the Drainage District.

Comment Text: For inter-dam reaches such as the Garrison Reach, construction activities would disturb the sediment in the river, causing it to flow downstream and accumulate in the delta. This action, over time, would increase aggradation in the delta, thereby increasing the backwater effect and river stage. If a sandbar was constructed in the upstream portion of the Garrison Reach, based on what is known about the geomorphic pattern of the reach one could conclude that the sandbar sediment would erode and end up downstream in the delta. It is suggested that if mechanical construction of sandbars occurs on inter-dam reaches, the sediment come from the downstream delta to alleviate this concern. This comment also pertains to the rest of the alternatives because mechanical ESH construction is included in all of them.

Comment Text: Alternatives 2, 4, 5 & 6 would all have significant adverse effects on the local levee districts due to the projected increased discharges ranging from 87 Kcfs to 126 Kcfs which corresponds to increases in river stages of up to 8 ft. in the Kansas City reach. Such radical flow increases would increase the annual cost of local levee districts as they must implement more frequent and higher flood protection management.

Comment Text: 3.11 - Commercial Sand and Gravel General Analysis: 1. Modifications in flow as presented in Alternatives 2, 4, 5 and 6 undermine the primary congressionally authorized purposes of navigation and flood control, making them problematic. 2. The states of Missouri, Kansas, Iowa and Nebraska own the bed of the lower river. The states have a sovereign right to their real estate and federal actions that compromise the real estates resources are a takeover in regard to states real estate and natural resources. 3. The use of the HEC-RAS model for decision making in the DEIS is flawed. Commercial sand dredgers have continually presented their objections to HEC-RAS being used for any permitting related decisions and the Corps has previously agreed during MRRIC sessions. In the DEIS however, this important point is missing from the document and needs to be included in the content for this section. 4. The DEIS fails to address the issue of sediment in the system and the lack of material movement. We call on the Corps to create a true sediment analysis that examines this important component for pallid sturgeon recovery. Changes in flow, without enhancing sediment load are not impactful and are a true waste of water in the system. 5. Regarding IRC construction and maintenance, the Corps must give commercial sand dredgers absolute assurance that these new habitat areas will not impact their operations by making its related regulatory strategy clear. Of utmost importance to dredgers are the issues of channel response, impacts to navigation, bed and hydraulic conditions.

Comment Text: Section & Page Number: 3.2.2.5, p. 3-46 - 3-47 "The flow release magnitude exceeds the power plant capacity at all projects except Big Bend. Past operations experience has shown that using the spillway or flood tunnels to release flow for a prolonged period results in the need for additional maintenance of these features and adds cost to operating the system. Long-term reliability of flow release features (spillway and/or flood tunnel) may also be affected. Finally, minor changes in dam safety risk from the use of additional release mechanisms and pool levels may occur. These risks have not been quantified at this time and would require a Monte Carlo analysis to evaluate changes in operation frequency and pool probability." At the end of this section on page 3-47, the following conclusion is made: "Impacts to river infrastructure would not be significant under any of the alternatives."

Comment: First of all, understanding the changes in dam safety risk is critical. If the flows proposed under Alternatives 2, 4, 5, and 6 increase the use of the spillways, affecting long-term reliability, not quantifying that risk is irresponsible. Second, concluding the section by saying that impacts would not be significant is premature because the risk to dam safety has not been assessed.

Comment Text: On page 3-40 in the discussion on degradation and bank erosion in the Garrison Reach it states the following: "Alternatives 4 and 5 could result in flow releases at Garrison Dam of 42,000 cfs for approximately 1 month. Considering the observations after recorded flows in 1996 and 1997, degradation of the river channel from the much shorter Alternatives 4 or 5 flow releases would perhaps be on the order of up to 0.5 foot in the mid-section of the Garrison Dam to Lake Oahe reach for each release. Considering the temporary impacts from individual releases and because Alternatives 4 and 5 full flow releases would occur only approximately every 10 or 7 years (Table 3-4), respectively, long-term impacts from additional degradation and streambank erosion under Alternatives 4 and 5 would be considered small." Degradation of 0.5 feet for each release is not small. Over the long-term, this degradation would accumulate and shift the water surface profile by several feet. Also, the ESH-creating releases would continuously move sediment from upstream to downstream, perpetuating (not reversing) the geomorphic pattern that already exists in the Garrison Reach. (See comments pertaining to "Inter-Dam Sequence" for Section 3.2.1.4, p. 3-20 - 3-22.) Skalak et al. (2016) studied the effect of the 2011 flood on the Garrison Reach. While the flows during the 2011 flood were much higher than the proposed ESH-creating releases, the results of the study still demonstrate that high flows can cause significant changes in geomorphology. The 2016 study determined the effects of the flood for each morphological zone of the Inter-Dam Sequence (see Skalak et al. 2013) for the Garrison Reach. The effects were as follows: 1. Dam Proximal Zone: River Mile 1390 to 1359 (Garrison Dam to Washburn); 40% of islands were eroded - equates to 44 years of work performed by the flood 2. Dam Attenuating Zone: River Mile 1359 to 1328 (Washburn to Sundown Acres); 13% increase in islands - equates to 43 years of work performed by the flood 3. River-Dominated Transitional Zone: River Mile 1328 to 1303 (Sundown Acres to Little Heart Bottoms - through Bismarck/Mandan); 25% increase in islands - equates to 8 years of work performed by the flood 4. Reservoir-Dominated Transitional Zone: River Mile 1303 to 1272 (Little Heart Bottoms to Fort Rice Boat Ramp); Change in islands was not measured On page 3-46 the final sentence of Section 3.2.2.4 states, "Impacts to geomorphology would not be significant under any of the alternatives." This statement is incomprehensible, especially in consideration of the fact that all of the alternatives affect the geomorphology of the river. The sole purpose of the ESH-creating releases is to cause significant change in the geomorphology of the river. Skalak, K.J, Benthem, A.J., Hupp, C.R., Schenk, E.R., Galloway, J.M., and Nustad, R.A., 2016, Flood effects provide evidence of an alternate stable state from dam management on the upper Missouri River: River Research and Applications. <http://onlinelibrary.wiley.com/doi/10.1002/rra.3084/full>

Comment Text: Section & Page Number: 3.2.2.4, p. 3-39 - 3-46 Comment: On page 3-39, this section regarding the "Impacts on Geomorphology from the Alternatives" states that effects to geomorphology due to Alternative 3 are not discussed because they would be similar to Alternative 1. Alternatives 1 and 3 do not include ESH-creating releases, so the hydrology is similar. They primarily rely on mechanical ESH construction. While mechanical ESH construction may not have a system-wide effect on geomorphology, that is not the case on a smaller, local scale. Constructing a sandbar could have morphological effects, such as shifting the thalweg of the river, which could cause a change in riverbank or sandbar erosion further downstream. A sandbar constructed in the upstream portion of the Garrison Reach would most likely erode and end up in the Oahe delta.

Correspondence Id: 239 **Comment Id:** 645392 **Coder Name:** jgutierrez

Comment Text: Section & Page Number: 3.2.2.3, p. 3-34 - 3-37 "Spring releases for ESH creation (Alternative 4) would start April 1 and would last between 35 days (at 60,000 cfs) and 175 days (at 45,000 cfs). Fall releases (Alternative 5) would be similar to spring releases, except they would start on October 15." Within the same section on page 3-37 it also states, "Impacts to hydrology are not anticipated to be significant under Alternatives 4 and 5." Comment: Besides the effect of the ESH-creating releases on reservoir elevations, which have been already discussed, any flows above the channel capacities identified in Table 3-2 (p. 3-16) would cause flooding. The channel capacity for the Fort Peck to Lake Sakakawea Reach and the downstream portion of the Garrison Reach is between 35,000 and 40,000 cfs. When the ESH-creating releases occur, the corresponding flow out of Garrison Dam is 17,500 cfs less than what is released from Gavins Point. This equates to releases ranging from 42,500 cfs (for 35 days) and 27,500 cfs (for 175 days). Any flows above 35,000 cfs, as determined by the hydraulic modeling, would exceed channel capacity in parts of the river and cause flooding. Saying that this change in hydrology is insignificant is disingenuous. In addition, implementing the fall ESH-creating release for 175 days would be infeasible. 175 days is nearly 6 months, making it last the entire winter. Typically, ice forms on the Garrison Reach in early to mid-December. As stated earlier, ice cover formation causes an increase in river stage of about 5 to 7 feet. High flows throughout the winter are unacceptable due to the increased risk of ice-induced flooding. In addition, ice cover on the river increases velocity for a given flow. Increased flows under ice conditions with the resulting increased velocities would increase erosion and negatively affect the longevity of sandbars.

Comment Text: Section & Page Number: 3.2.2.3, p. 3-28 "Overall, the elevations in the reservoirs are dominated naturally by precipitation (i.e., rainfall and snowmelt) in the watershed of the upper river (aside from System operation by the USACE). Although the six alternatives could affect the elevations in the reservoirs to varying extent throughout the year, these variations are small compared to natural variations." **Comment:** It is agreed that the effect of the alternatives on reservoir elevations is small compared to natural variations; however, that does not mean that the effect itself is insignificant. For example, the effect of the ESH-creating release on the elevation of Lake Sakakawea is a drop of up to 10 feet (discussed further in comment regarding Section 3.1.1, p. 3-4). In addition, some of the alternatives (2, 4, 5, and 6) cause lower reservoir levels during historic drought periods and the incremental effect during a drought (or flood) can be devastating. Plots of the three upper reservoirs during the historic drought periods are attached.

Comment Text: "The 'rules' governing System operation during periods of drought and high runoff for the action alternatives are generally the same as current System operation under the No Action alternative. Therefore, the effects of the action alternatives on reservoir elevations and releases are relatively small compared to the variation caused by the extreme hydrologic events in the POR." **Comment:** It is agreed that the action alternatives do not substantially affect operations during climate extremes, such as floods and extended drought. However, some of the action alternatives, in particular Alternatives 4 and 5, cause significant changes in reservoir elevations and releases from Garrison Dam. Tables 1 and 2 display the volume released from Garrison Dam and reservoir elevation changes of Lake Sakakawea for each instance in the modeled period of record when a full ESH-creating release was implemented

(values were calculated from the Hydrovisualization Tool, version 2.27). [Table 1 - Alternative 4: Spring ESH-Creating Release; Table 2 - Alternative 5: Fall ESH-Creating Release] First and foremost, when a full ESH-creating release is implemented, the volume of water released is not insignificant. For purposes of comparison, the consumptive water use for the entire State of North Dakota in 2015 was about 343,000 acre-feet. The volume of water released to create ESH is up to nearly eight times the annual consumptive water use for our entire state. For both ESH-creating releases, Lake Sakakawea drops up to 10 feet in 5.5 weeks. Among other things, this could negatively affect boat access to the reservoir, and access to water for irrigation and municipal water supplies.

Comment Text: Section & Page Number: 3.1.1, p. 3-3 Comment: This section states that the cross sections for the HEC-RAS model were based on 2012 channel geometry. As the 2011 flood scoured the channel and moved the reservoir deltas downstream, and we are already seeing the effects of sedimentation, the 2012 geometry will generally underestimate the water surface profile. While this does not prevent comparison of the alternatives, it should be noted that the water surfaces will likely be higher than modeled.

Comment Text: The sand and gravel dredging industry is dependent on sediment load, yet the Corps failed to accurately analyze the amount of sediment in the system. The Corps also failed to analyze how the alternatives would impact sediment loading. The Corps' use of a 20-year period to extrapolate for the 82-year period of analysis to analyze for sediment is insufficient. A robust sediment model needs to be created to adequately analyze the impacts of sediment loading and their effect on the sand and gravel industry in the Final EIS.

Comment Text: Reservoir sedimentation also has impacted the integrity of the very important flood control pools. The Corps has indicated capacity of the flood control pools is currently at or near the minimum size (16.3 MAF) and that any future sedimentation will require storage capacity to be removed from the Carryover Pool and the Sediment Pool to maintain the 16.3 MAF of flood control necessary. If the Corps simply adjusts the elevations of the top of the Carryover Pool downward to maintain the flood control storage capacity without also making adjustments to the Carryover Pool, further impacts to downstream flow support will occur. Based on the concerns outlined above, the State of Missouri requests the Corps clarify and assess the manner in which the system will operate in the future over changing environmental conditions (changes in sedimentation and hydrology).

Comment Text: Unfortunately, following the issuance of the 2004/2006 Manual, the Permanent Pool is not where the Corps has accounted for sediment. Since 2004, the Corps has largely allocated the sedimentation to the Annual Flood Control (29,000 acre-feet of storage loss) and the Carryover Pools (771,000 acre-feet of storage loss). Furthermore, the Corps viewed the operational guide curves as numerically fixed, which diminished the capacity and benefits of the Carryover and Annual Flood Control Pool. The numerically-fixed guide curves and reduction in pool capacity create a condition where the downstream flow support level established by the 2004 Master Manual fail to perform as presented (see Table 2). These very real impacts to downstream flow support resulting from past management actions are neither mentioned nor assessed in the DRAFT EIS as required under CEQ regulations.

Comment Text: The No Action Alternative already subjects levee systems in downstream reach of the Missouri River to bi-modal spring rises. In the Kansas City area this has some moderate impacts on the local levee operations due to the fact that some units begin closing sluice gates and activating pump stations as early as Stage 19.5 ft., and in other areas with lesser levels of protection has greater impact. Without the spring rises local levee districts would not need to take action as often or for as long, thus conserving operational cost, flood fight activity and risk.

Comment Text: Unfortunately, FWS' proposal to protect the pallid sturgeon was not implemented during the 10 years before ISAP's conclusion and has not yet been implemented three years later. The Corps focused primarily on managing flows for downstream navigation, while attempting to fit all other uses into prescribed navigation targets. However, the expected amount of navigation was never achieved, and most navigation on the Missouri is limited to small barge trips of about a mile used to mine sand and gravel from the river and transport it to the shore.¹⁸ The Corps rejected the implementation of low summer flows and the connection to the floodplain, stating that these were not feasible objectives under other project authorizations.¹⁹ Despite the opportunity to implement an adaptive management plan, the Corps instead kept fish and wildlife at the bottom of the barrel. As of 2016, the Corps is below target on all flow-related RP As for the pallid sturgeon.²⁰ Since some researchers have suggested that the pallid will be extirpated by 2018²¹ without further action, the Corps has effectively allowed the pallid to slide ever-closer to this fate. Since the original 2000 listing, the Corps has only fully implemented three spring pulses, and never to the levels requested in the Biological Opinion.²² Warm water discharges from Fort Peck were not implemented during the 8-year period following the Biological Opinion, and were eventually shuffled aside as fisheries managers pursued other possible options that would protect the pallid sturgeon.²³ Experts focused instead on fish passage on the Yellowstone River, requiring the Corps to allocate funds authorized for this purpose from the Water Resource Development Act of 1999.²⁴ However, this project does not provide evidence that it will adequately support the pallid sturgeon as currently designed.

Comment Text: The DEIS (V1-page 150) focuses on hatchery practices. The League is concerned that the Corps places too much emphasis on hatchery raised pallids for the Missouri River. Stocking creates a population that is not self-sustaining. Our concerns about stocking also include disease and water quality issues in the hatcheries and the effects on the health of the fish raised. If hatchery pallids are transporting disease to wild fish, then restoration efforts are going backward. We also have concerns about the high cost of raising pallids in the hatcheries. We encourage more habitat restoration in the upper and lower river to ensure natural production and recruitment.

Comment Text: In regards to the Intake Project on the Yellowstone River (V1-page 122), we have concerns about the project's proposed fish passage. The final EIS should articulate how the Corps will measure if pallids are successfully bypassing the intake and spawning. The Intake Project is a tremendous expense (57-60M) from the MRRP. This amount demands more than just an assumption that it will work.

Comment Text: Alternative 5 - The League has concerns with Alternative 5. This alternative is contrary to the natural historic hydrograph of the river. Alternative 5 would have large flow releases in the fall instead of the spring, as in the natural hydrograph. We believe any habitat created through fall releases would suffer serious losses to wind and ice erosion over the winter. This would create short lived habitat that would be largely unused while least terns and piping plovers are on their wintering grounds far south of the Missouri River. We also have concerns with this alternative's potential impacts on pallid sturgeon and other native fish species, with such a large release at an unnatural time of year for the Missouri River.

Comment Text: Similarly, the low summer flow found in Alternative 2 has not been shown to be effective. The only explanation of its effects on the pallid sturgeon is that "the USFWS 2003 Amended BiOp (USFWS 2003) also called for the modification to System operations to allow for flows that are sufficiently low to provide for SWH as rearing, refugia, and foraging areas for larval, juvenile, and adult pallid sturgeon." 112 The MRRMP-EIS does not explain the benefits of low summer flow in terms of how much SWH would be created and thus does nothing to prove that it is a beneficial management action for the pallid sturgeon. In addition, low summer flow "would only be implemented in the two years following implementation of a complete bimodal spring pallid sturgeon flow release." 113 This would make the implementation of low summer flow infrequent because "modeling based on an 82-year POR, indicate that in practice the bimodal spring pallid sturgeon flow releases would likely only meet the conditions for implementation once in every eight years," meaning that the complete implementation of these flows would occur even less frequently than this. 114 The lack of explanation about the benefits of low summer flow, along with its infrequent implementation, show that the Corps provides no evidence of the effectiveness of this management action. It is possible that because there is a lack of evidence showing a positive effect of the low summer flow on the pallid sturgeon, the low summer flow could be ineffective. NEPA requires use of the best available scientific information, which in turn necessitates the consideration of other viable alternatives.

Comment Text: 1) The Use of the Shovelnose as Surrogate Species Lacks Support For much of the EIS, where data are unavailable or scarce on the pallid sturgeon, life history characteristics of the shovelnose are used. A number of reasons exist that could undermine the credibility of this approach, including differences in drift rates and distance, diet, and habitat use. For these reasons, the Corps should consider shifting the alternatives to rest solely on what is known about pallid sturgeon, rather than use the surrogate species approach. Specifically: -The transition from the drifting to the benthic life stage occurs in only 6 days after hatch for shovelnose sturgeon and at 11-17 days after hatch for pallid sturgeon. 11 -Drift simulations have found that average larval shovelnose sturgeon may drift from 94 to 250 km and the average larval pallid sturgeon may drift from 245 to 530 km. 12 -While both fish consume larval caddisflies, the diet and thus feeding position in the river differ greatly. Pallid sturgeon consume fish in the water column, including chubs, shad, and other minnows. Shovelnose sturgeon were benthic feeders, mostly eating insects that live on the river bed or in the drift. 13 -Pallid sturgeon used sandy substrate, midchannel bars islands, and areas with riparian vegetation more often than shovelnose sturgeon. 14

Comment Text: What is the evidence supporting this management action and the high estimated cost to create it? What other management actions were considered to benefit survival of age-0 pallid sturgeon? There is only a single statement in Vol 2 of the DEIS identifying benefits of channel widening for pallid sturgeon recruitment: P 89. L7-9 (also on P88 L9-10 of DSAMP appendices). Under Alternatives 3-6, construction of habitat to support early life history requirements of pallid sturgeon would occur following the /RC (interception and rearing complexes) concept. Best available science indicates that future acreage required to construct IRCs would most likely be achieved through channel widening. One expects this 'best available' science' would be described in the pallid sturgeon effects analysis volumes. However, in Jacobson et al 2015 (P26) there is only a single reference to channel widening as an action to benefit pallid sturgeon and it is unsupportive or equivocal as to the benefits of SWH - including channel widening: The report from the assessment (Schapaugh and others, 2010) cited the HAMP as an excellent design to achieve active adaptive management; however, the report also documented that assumptions underlying the BACJ designs were not being met under real-world conditions, and, therefore, the ability to detect effects of SWH was limited. In particular, the authors reported that the actions of dike notching and channel widening did not result in detectable changes in the fish community. Moreover there is not a single reference to observed or proposed benefits of channel widening in the Pallid Sturgeon Effects Analysis Integrative Report (Jacobson et al 2016) or as part of any working hypothesis linking management of the Missouri River to pallid sturgeon population dynamics (Jacobson et al 2016b). There are two references to channel widening in the DSAMP (P43, L 23; Table 47, P376) - but both just describe implementing the management action, not its anticipated benefits. Numerous references to channel widening are in the DAMP appendices, but again, all but the aforementioned statement that best available science supports channel widening, are details of acreages, locations and implementation processes.

Comment Text: We are concerned by the absence of sufficient study of benthic macroinvertebrate food sources in the planned IRC projects at Baltimore Bend and Searcy Bend (Tadpole Island). The BACI (Before-After-Control-Impact) study designs specified in the DEIS have utilized benthic trawls to describe fish community assemblages, according to posters presented at the Missouri River Natural Resources 2017 conference (MRNRC Conference and BiOp Forum 2017 Habitat: The Pathway to Recovery Poster Abstracts,: Interception-Rearing Complexes: Age-0 Sturgeon Baseline Monitoring during 2016 Author(s): Nathan J.C. Gosch, Todd

R. Gemeinhardt, Marcus L. Miller, and Joseph L. Bonneau) and (same conference, Title: Pre-Treatment Fish Communities of Two Missouri River Bends, Prior to IRC Construction Author(s): Thomas C. Boersig, Jacob N. McQuaid, and Kyle W. Winders) Since a major hypothesis concerns Age-0 pallid sturgeon ability to forage and feed in these habitats, we believe benthic macroinvertebrate community assemblages should be described and studied rather than assuming that prey food, generally, will be present.

Macroinvertebrate Bray-Curtis Similarity Indexes and or dissimilarity indexes should be created in all phases of the BACI for IRC sites and their control comparatives. These same macroinvertebrate prey may, also, be part of the food web for the fish community assemblages already studied and cited above. This kind of data would seem essential if additional bioenergetics analysis is to be accomplished for these, or additionally planned future sites.

Comment Text: Perhaps most disturbing to me is the plan's purported dependency on a high level of science to make decisions while the plan contains glaring inaccuracies presented as the "best available science". An example is the continued mention of interstitial hiding by post-hatch free embryos and its inclusion in decision-trees within the plan. While there has never been evidence of use of interstitial space by pallid sturgeon hatched free embryos, evidence from Keenlyn, Holm, Kappenman, Braaten and Delonay provide evidence that interstitial hiding is not used by pallid sturgeon. If this is a demonstration of how slow accurate information is incorporated into the MRRMP decision-making process, meaningful management actions to benefit pallid sturgeon will not occur in reasonable timeframes if at all.

Comment Text: But beyond that, where are provisions for designation of critical habitat for the endangered pallid sturgeon; for unbalanced reservoirs to address the situation at a particular reservoir; for the application of the best science currently available? Habitat loss, fishing and caviar harvesting, entrainment and watercraft propellers, contaminants, hybridization, invasive species, and iridovirus all threaten the endangered pallid sturgeon. None of the alternatives provide adequate response. The pallid sturgeon requires shallow-water habitat. Designation of critical habitat is necessary! The Corps of Engineers seemingly acknowledges that with the phrase "avoid jeopardizing the continued existence of pallid sturgeon or its critical habitats" in the accompanying Draft Science and Adaptive Management Plan. Perhaps having unbalanced reservoirs as a management tool in the Missouri River Mainstem Reservoir System Master Water Control Manual is adequate, but perhaps not.

Comment Text: Land acquisition by the federal government removes the property from the tax base for local government. The federal Payment In Lieu of Taxes (PILT) program is designed to offset some of the loss in revenues, but PILT payment levels can vary significantly from year to year, resulting in considerable difficulty in budgeting and planning for local governments. In any case PILT does not replace the tax revenues and is capped at \$2.64 per acre (FY 2016). The acquisition target for the no action Alternative 1 is 5,267 acres, Alternative 2, 33,462 acres and for Alternatives 3-6, 1,417 acres. Conservative estimates for average property taxes are \$5.00-\$8.00 per acres in Missouri and \$20-\$35 per acre in Nebraska. With the PILT capped at \$2.64 per acre, property tax revenue impacts can be locally severe, especially under Alternative 2. We believe the tax impacts listed in the DEIS are understated. Additionally, the DEIS lists annual impacts, which creates a perception of smaller impacts than are really incurred. Multiply the property tax impacts for 10, 20 or 50 years, and those impacts run into tens of millions of dollars. This is especially true for Alternative 2, which could have devastating effects on local revenues. Property taxes are not the only sources of revenues to local governments that are directly tied to productive cropland. The economic activity generated by farming impacts everything from individual and corporate federal income taxes down to local sales taxes, special use taxes, personal property taxes, etc. An analysis that limits itself to the impacts of property tax is incomplete and inaccurate and grossly underestimates the revenue impacts to local government. Further study of those impacts is necessary before management actions are taken. The paragraph on Other Social Effects

limits its analysis only to impacts of land acquisition and takes pains to point out the small percentage of land that would be acquired by the federal government. We believe the impacts are understated and reiterate that management actions can still be far more impactful than the act of acquisition.

Comment Text: 3.10 Land Use and Ownership General Analysis: 1. We appreciate the Corps effort to develop empirical economic modeling. Modeling to attempt to predict job losses, sales impacts and the property tax impacts to local government due to land use and ownership changes is appropriate. However, economic modeling, especially the truncated version employed to develop the DEIS, is anything but scientific. 2. It is well known the even small data or assumption errors can create fundamentally inaccurate predictions. Inaccurate assumptions, the omission or inclusion of certain data sets and the accuracy of the data sets are just a few of the limitations of modeling. Assumptions of relationships and cause and effect of various factors must be made for the baseline or starting point of modeling. 3. Synergistic effects of interrelated economic impacts are missing from the model, causing the overall economic impacts of changes to land use and ownership for all alternatives to be substantially understated. For example, the modeling does not account for the impacts of navigation on transportation costs and agricultural profitability. There are scores of examples like this in the DEIS. Additionally, the land use modeling limits baseline assumptions to those cropland acres that will be taken out of production by the result of productive land being purchased and repurposed by the federal government. Land purchases are the only metric considered. The wide range of management actions include impediments to interior drainage that can drastically alter land use and productivity. Impacts from power generation costs, local water supply, increased truck traffic on public roads as the result of

potential impacts on navigation, etc., must be considered and analyzed. Those elements and others have massive impacts on NED, RED and OSE outcomes, but they're not part of the DEIS modeling. Without inclusion of the broad impacts of critical economic interactions in the model, its outcomes are oversimplified and understated. In brief, the model is too simplistic and too limited in scope.

Comment Text: In summarizing the change in economic activity for all agricultural land acquisition (Table 15, page 19-20), the Corps states that "Missouri would experience the greatest adverse impacts to jobs and income, with a reduction of less than one job and \$19,000 in income." A worst-case scenario estimate of one job lost and \$19,000 in income is grossly underestimated because the Corps did not include indirect labor economic impacts in their analysis. A thorough and accurate economic analysis of land acquisition would help stakeholders understand the impact on the regional economy. In the Final EIS, the Corps needs to identify the correct assumptions for its economic analysis and appropriately estimate the numbers.

Organization: Missouri Department of Natural Resources

Commenter: Carol S Comer **Page:** **Paragraph:**

Comment Text: Economic evaluations On the same topic of acquired acres the Corps assumes that acres offered to the Corps from willing sellers will have been recently in crop production. Thus the Corp values their contribution to crop totals the same as other acres in the area. That is a reasonable assumption only to a point. It is likely that some, perhaps a majority, of willing sellers are willing to sell to the Corps because they have problems with productivity on their lands. Problems may be due to frequent flooding. If so removal of those acres from the agricultural base would save taxes in flood insurance and would have a lower proportional impact on regional crop productivity than other acres. The Corps also mentions loss of tax base as an economic loss. Again if such acres from willing sellers are more prone to production problems, that would reduce their past contribution to the tax base. The Corps mentions PILT payments as a buffer against that loss but does not incorporate any formula or estimate to assess that. It does though give a Dept. of Interior reference and expects the reader to figure it out.

Correspondence Id: 219 **Comment Id:** 643498 **Coder Name:** jgutierrez

Comment Text: The impacts to land acquisition are understated in the Section 3.10 of the DEIS. Land Acquisition by the Corps removes property from the tax base for local government and this cost should be accounted for in the economic considerations. Property taxes are a source of revenues to local governments and schools that are tied to the productive cropland. The economic activity generated by farming, impacts local sales tax, personal property tax, special use taxes, and these impacts are underestimated in the analysis. Any conservation management plan should be voluntary and provide incentives to private landowners for protecting or enhancing habitat for the species needing protection. Non-participants in voluntary species conservation management plans should not be held to the standards of the plan. Benefit-cost ratio analysis for any alternative must result in higher benefits than the cost. Mitigation or replacement of habitat should be applied only in areas where conversion of the habitat is significant in relationship to the total amount of habitat available in the area.

Comment Text: It is important to recognize that agriculture has been, and will continue to be, the driving force behind North Dakota's economy, contributing over \$32 billion in economic activity annually. That makes agriculture the largest sector of North Dakota's economy, supporting twenty-four percent of the state's workforce. North Dakota's farmers and ranchers own, operate and manage nearly forty million acres, rank number one in the nation in the production of ten commodities, and produce over fifty commodities in total. Because of North Dakota's vast global export markets, the removal of any agricultural land would affect production for North Dakota's farmers and ranchers, having a far reaching detrimental impact on North Dakota, and its global partners. As such, floodplain connectivity due to increased flows and the removal of agricultural land from production are of great concern to the North Dakota Department of Agriculture (NDDA). The removal of any amount of agricultural land from production leaves a tremendous effect to the overall economy of the state. It is an issue much greater than the suggested loss in property tax revenue. Farmers and ranchers must retain ownership and access to operate agricultural land to better support a balanced ecosystem. NDDA finds the encouragement of floodplain connectivity to be premature based on the lack of research available.

Comment Text: On the same topic of acquired acres the Corps assumes that acres offered to the Corps from willing sellers will have been recently in crop production. Thus the Corp values their contribution to crop totals the same as other acres in the area. That is a reasonable assumption only to a point. It is likely that some, perhaps a majority, of willing sellers are willing to sell to the Corps because they have problems with productivity on their lands. Problems may be due to frequent flooding. If so removal of those acres from the agricultural base would save taxes in flood insurance and would have a lower proportional impact on regional crop productivity than other acres.

Comment Text: 3.11 - Commercial Sand and Gravel General Analysis: 1. Modifications in flow as presented in Alternatives 2, 4, 5 and 6 undermine the primary congressionally authorized purposes of navigation and flood control, making them problematic. 2. The states of Missouri, Kansas, Iowa and Nebraska own the bed of the lower river. The states have a sovereign right to their real estate and federal actions that compromise the real estates resources are a takeover in regard to states real estate and natural resources. 3. The use of the HEC-RAS model for decision making in the DEIS is flawed. Commercial sand dredgers have continually presented their objections to HEC-RAS being used for any permitting related decisions and the Corps has previously agreed during MRRIC sessions. In the DEIS however, this important point is missing from the document and needs to be included in the content for this section. 4. The DEIS fails to address the issue of sediment in the system and the lack of material movement. We call on the Corps to create a true sediment analysis that examines this important component for pallid sturgeon recovery. Changes in flow, without enhancing sediment load are not impactful and are a true waste of water in the system. 5. Regarding IRC construction and maintenance, the Corps must give commercial sand dredgers absolute assurance that these new habitat areas will not impact their operations by making its related regulatory strategy clear. Of utmost importance to dredgers are the issues of channel response, impacts to navigation, bed and hydraulic conditions.

Comment Text: Additionally, the Corps failed to analyze the effect of the one-time flow event in Alternatives 3, 4, and 5. In light of this, it is difficult for stakeholders to evaluate and provide meaningful feedback on impacts that were not analyzed. For the flow scenarios in which the Corps did assess impacts to the sand and gravel industry, the analysis is incomplete. The Corps failed to

analyze the economic impact of flow scenarios. In the Final EIS, the Corps needs to correct these deficiencies if the analysis is to be considered sufficient.

Comment Text: Like the discussion of Alternative 4, the discussion of Alternative 5 shows differing results in the navigation and sand and gravel sections. Table 6 shows a 0.5% difference in NED between Alternative 5 and Alternative 1, then considers it a negligible impact for sand and gravel dredging. However, as shown in Table 7, "Alternative 5 would have a relatively small adverse impact on navigation benefits compared to Alternative 1 because it could reduce the annual NED by \$0.006 million, approximately 1 percent of annual NED benefits."¹⁵⁹ While these percentage differences are not as significant as some of the other alternatives, they show conflicting results (negligible impact versus a small adverse impact). For the last alternative, Alternative 6, there is also a discrepancy between the two NED values found in each section. The sand and gravel industry section shows a negligible 0.4% difference in the NED between Alternative 6 and Alternative 1, as indicated in Table 6. Table 7 below, summarizing the navigation section, shows that "a relatively large adverse impact would occur to navigation under Alternative 6 by reducing annual NED by \$0.042 million, approximately six percent of annual NED benefits."¹⁶⁰ Once again, the two sections reach contradictory conclusions despite the similarity of the activities. Table 8 below compares the percentage difference in NED for each alternative relative to No Action for each industry. Comment Text: Regarding Alternative 3, Table 6 shows that the NED difference for the sand and gravel industry differs from Alternative 1 by 0.1 %. Table 7 below, which outlines the impacts of each alternative on navigation compared to Alternative 1, shows a difference of \$0.002 million in NED from Alternative 1, a difference of 0.28%. While the percentage values for Alternative 3 in Tables 6 and 7 are similar (0.1 % difference on Table 6 compared to 0.28%, on Table 7), the results are presented in conflicting manners. According to the section on sand and gravel dredging, "any NED impacts to the commercial sand and gravel dredging industry under Alternative 3 would be negligible due to the measurable but very small percentage change from Alternative 1."¹⁵⁵ However, the navigation section states that "Alternative 3 would have a slightly beneficial impact on navigation compared to

Alternative 1,"¹⁵⁶ even though the values differ by less than two-tenths of a percent. How can there be a negligible impact on one industry (sand and gravel dredging) but a benefit impact to the other industry (navigation) where the two are extremely similar? [Table 7: Impacts to Navigation Relative to No Action] The same factors are at work in the comparison of Alternatives 4 through 6 in the navigation and sand and gravel sections. The discussion of Alternative 4 in the two sections is like that of Alternative 2. In Table 6, sand and gravel dredging shows a -0.2% "negligible" difference between Alternative 4 and Alternative 1, while in Table 7, navigation shows an "adverse" difference of approximately 6%, "decreasing the annual NED by \$0.045 million. ¹⁵⁷ The navigation section further contradicts the sand and gravel section by stating that "relatively large adverse effects to commercial sand dredging from shortened navigation seasons would occur in some years." ¹⁵⁸ Again, it is important to note that "commercial sand dredging" differs from commercial navigation, which does not include the sand and gravel industry's barge traffic.

Comment Text: Both the navigation and sand and gravel dredging sections of the MRRMP-EIS include a breakdown of how each alternative would impact the industries relative to the No Action Alternative. The conclusions reached for each of the alternatives in each of the industries are confusing and self-contradictory, rendering the analysis virtually useless. Below, Tables 6 and 7 show the impacts of each alternative on the navigation and sand and gravel dredging industries. Table 6 clearly shows that there are no significant impacts to the sand and gravel dredging industry from any of the alternatives. The only quantifiable difference between the analyses of each of the alternatives can be found in their National Economic Development (NED) values. Each alternative is less than 1 % different from the No Action Alternative, which itself allegedly has negligible impacts on sand and gravel dredging. [Table 6: Impacts to Sand and Gravel Dredging Relative to No Action] However, when the section on sand and gravel dredging impacts is compared to the section on navigation impacts, there are many contradictions. The types of commodities that travel along the Missouri River are broken "into four broad categories . . . commercial sand and gravel, waterway improvement materials, other commercial cargo, and oversized goods."¹⁵⁰ Of these four categories, "since 2000, sand and gravel has represented greater than 85 percent of the commodities shipped on the Missouri River."¹⁵¹ However, there is a difference between "commercial sand and gravel" and "other commercial cargo" navigation on the river. The sand and gravel navigation was already considered in its own section, so it should be excluded from the analysis in the navigation section. Since the MRRMP-EIS treats the majority of navigation on the Missouri River as sand and gravel dredging, one would think that the navigation sections of the MRRMP-EIS would reach a conclusion similar to that reached in the sections on sand and gravel dredging - that the impact is negligible. Under the sand and gravel dredging section, a NED value was calculated "based on impacts related to transportation of material" where one of the values was "navigation transportation savings."¹⁵² Under the navigation portion, a NED value was also "calculated by subtracting the

change in non-routine repair, replacement, and rehabilitation (R, R, & R) costs from the transportation savings."¹⁵³ By using the same metrics to calculate each of the NED values, both industries should show a substantially similar impact among the alternatives. While the No Action Alternative seems to have similar results for both navigation sand and gravel dredging, the other alternatives have conflicting NED values. Table 6 above shows that the Corps has determined that the NED effects for Alternative 2 when compared to No Action are negligible with only a 0.5% difference. However, the analysis of NED effects found in the navigation section reaches a different conclusion about sand and gravel dredging: Alternative 2 would have an adverse impact to navigation by reducing NED by \$0.028 million annually, approximately four percent of annual NED benefits, due to the low summer flow reducing navigation season. There would be relatively large adverse effects to commercial sand dredging jobs and income in years with low summer flows, but negligible impacts to regional economic conditions. ¹⁵⁴ The difference between the two NED analyses on the impacts of Alternative 2 to the two industries is unexplained because the same factors were used to calculate both and a clear majority of materials currently transported on the Missouri River is performed by the sand and gravel industry (typically transporting its products fewer than ten miles each trip).

Correspondence Id: 240 **Comment Id:** 644962 **Coder Name:** jgutierrez

Comment Text: 1. The importance of sand and gravel dredging is overstated because it is not an authorized use of the Missouri River. The primary use of dredged sand and gravel is for the "construction industry, including road and highway construction," and "the Missouri Department of Transportation is one of the largest customers of sand from the Missouri River."¹⁴¹ Dredging operations are centered around the sand and gravel companies' on-shore processing plants, typically taking place no more than 7- 10 miles upstream and no more than 3- 9 miles downstream from a plant. ¹⁴² The average production volume of sand and gravel dredged from the Missouri River between the years 2010 and 2015 was 3,763,577 tons. ¹⁴³ Figure 1 below shows that in recent years, sand and gravel barge traffic volume has fallen below the five million ton goal for navigation on the Missouri River, even when combined with commercial navigation. In addition, it shows a large difference between commercial navigation and sand and gravel dredging. This difference shows that actual commercial navigation on the river is negligible in comparison to sand and gravel dredging, and that the navigation statistics reported in the MRRMP-EIS rely mostly on sand and gravel barge traffic: ¹⁴⁴ [Traffic graphic] The sand and gravel dredging industry is regulated through permits, and "every five years the dredgers must reapply for Department of the Army permits."¹⁴⁵ In 2003 and 2004, the Corps "received 10 applications from commercial sand and gravel companies for permits to extract sand and gravel from the [Lower Missouri River]. In August 2007, the USACE Kansas City District authorized four applicants to continue existing dredging operations."¹⁴⁶ Thus the Missouri River dredging industry is relatively small. But despite its size, the industry manages to be quite environmentally destructive: "the reaches of the river most degraded- Kansas City, Jefferson City, and

St. Charles- were found to coincide with areas where commercial sand and gravel dredging was the greatest."147 The dredging industry may even have its own adverse impact on the species because "dredging and associated river bed degradation could be contributing to impacts on habitats of federally listed threatened or endangered species."148 When discussing the impacts that the ESH construction of Alternative 2 would have on the sand and gravel dredging, the Corps erroneously states "each project will be designed to not impact other authorized purposes including sand and gravel dredging as described in Section 2.5.3.1."149 But even if the impacts were stated consistently throughout the MRRMP-EIS, sand and gravel dredging is not a congressionally authorized use of the Missouri River and should afford no special protection in the development of alternatives. Therefore, the sand and gravel dredging industry should not be given undue consideration in the MRRMP-EIS. If anything, reducing dredging activity would seem to accrue benefits to species protection.

Comment Text: D. The MRRMP-EIS Overstates Impacts to Navigation and Sand and Gravel Dredging. The Corps "operates the System to serve eight congressionally authorized project purposes of flood control, navigation, irrigation, hydropower, water supply, water quality, recreation, and fish and wildlife."138 The Missouri River is also used for sand and gravel dredging, which is not statutorily authorized. Since navigation is one of the System's eight authorized purposes, 139 an analysis of the Alternatives' impacts on navigation is a permissible consideration. However, the Corps overstates those impacts where it analyzes sand and gravel dredging under the topic of navigation as well as under its own category, particularly since the conclusions of the MRRMP-EIS in the section on sand and gravel dredging conflict with the conclusions in the navigation section. Navigation impacts are also overstated due to the low volume of actual commercial navigation on the Missouri River. Figure 1 below, which is provided in the MRRMP-EIS, shows that the commercial barge traffic volume on the Missouri River falls far below the navigation target of five million tons of commercial barge traffic. 140 In addition, the scale and weight of navigation and sand and gravel dredging are misleadingly inconsistent. Furthermore, the Corps overstates impacts to the sand and gravel dredging industry because it is not a congressionally authorized use of the river.

Comment Text: Further, with pulse constraints at 126,000 cfs, interior drainage issues will be significant. Its impossible to tell how many flap gates will be closed and how many fields will be inundated by percolating ground water or local rainfall that cannot escape due to the closed flap gates because modeling was not done for interior drainage. The economic impacts of such high flows for extended periods and the lack of information due to lack of modeling makes Alternative 4 intolerable. Economic impact conclusions on interior drainage are incomplete and inaccurate. Flows are 77 percent higher at Kansas City (126,000 CFS for Alternative 4 versus 71,000 CFS for the no action alternative). Impacts to ground water, flap gates and pumping systems would be 77 percent more severe than with the no action alternative. The abbreviated analysis for interior drainage needs substantial recalibration. All economic conclusions and modeling on Alternative 4 are inaccurate and incomplete due to the failure to provide robust and accurate modeling and impact data on interior drainage. This alternative is unacceptable because no one knows what the impacts to NED, RED and OSE will be since the DEIS stipulates that economic analysis of the floodplain could not be completed. Translation of the impacts to the four sample sites to the rest of the floodplain was not even attempted and extrapolation from the four sites to other levee areas was not feasible since the hydraulics, hydrology and drainage varies between sites.

Comment Text: In this section, the DEIS indicates that the impacts to flood risk management were evaluated using two of the four economic account models: NED and OSE. By only using these two accounts to evaluate the impacts to flood risk management, the DEIS has omitted key data points resulting in a major understatement of the costs and impacts to Mississippi River flood control interests. The failure to perform a comprehensive RED analysis to measure the impacts to flood risk management on the Mississippi River is very concerning. In addition to this, the DEIS does not indicate the reason an RED impact analysis was not performed. A comprehensive RED analysis for the Mississippi River, if done properly, would illustrate the negative impacts of these alternatives on local and regional economic conditions, such as employment, labor income, sales, sales tax revenue, flood damages, and other potential costs.

Comment Text: Section 3.12.4.7 - Alternative 4 - Spring ESH Creating Release The DEIS says Alternative 4 has a relatively negligible adverse impact on interior drainage relative to No Action with a total increase in average annual NED impacts of \$389 or less that 0.1 percent Flow constraint in the No Action alternative at Kansas City are 71,000 cfs. Flow constraints under Alternative 4 are 126,000 cfs 77 percent higher than the No Action alternative. Yet, the impact is only \$389 a year. And, even though the flow constraints are 77 percent higher, no RED analysis was performed because the DEIS claims the impacts are so small its not worth the effort. Again, this claim is very hard to believe.

Organization: Coalition to Protect the Missouri River

Correspondence Id: 228 **Comment Id:** 645572 **Coder Name:** jgutierrez

Comment Text: Section 3.12.4.5 - Alternative 2 - USFWS 2003 Biological Opinion Projected Actions Here, the DEIS contradicts itself by showing NED, totaling \$1.17 million annually for only the four levee sites that were studied. When multiplied by the hundreds of levee sites in the floodplain, if these sites are representative then annual impacts would be in the hundreds of millions annually. The assessment methodology is anything but methodical and lacks all credibility. The DEIS then strains credibility even further by stating impacts to RED in any year would be so negligible that a full RED analysis was not undertaken on the interior drainage NED effects. NED impacts on only four levee sites were deemed to be over a million dollars annually, but RED impacts are so small that no one bothered to study them? That reasoning is unfathomable. These impacts occur with the current management actions in place, with flow constraints at Kansas City of 71,000 cfs. The DEIS actually claims Alternative 2 has relatively small beneficial impacts relative to No Action. The flow constraint for the No Action alternative at Kansas City is 71,000 cfs. The flow constraint for Alternative 2 is 87,000 cfs at Kansas City. Thats a 22 percent increase in flow, which raises the river stage above the releases of the No Action alternative. Yet, the modeling shows the NED impact to be smaller. The site with the largest impact is MRLS 488L, which would experience a decrease of \$10,214 in average annual flood impacts. According to the DEIS, higher water levels mean less flooding. That leads us to believe its manual calculations (the hydrology model doesnt run on todays computer) need to be checked for errors and the process employed to review the logic, accuracy and credibility of the DEIS needs a major overhaul. It is not logical, accurate or credible.

Comment Text: Section 3.12.3.7- Alternative 5 - Fall ESH Creating Release All economic conclusions and modeling on Alternative 5 are inaccurate and incomplete due to the failure to provide robust and accurate modeling and impact data on interior drainage. This alternative is unacceptable because no one knows what the impacts to NED, RED and OSE will be since the DEIS stipulates that economic analysis of the floodplain could not be completed. In addition, translation of the impacts to the four sample sites to the rest of the floodplain was not even attempted and extrapolation from the four sites to other levee areas was not feasible since the hydraulics, hydrology and drainage varies between sites. The fall pulse has the same high flow rates that significantly increase flood risks and cause interior drainage impedance. The difference between Alternative 4 and Alternative 5 is that under Alternative 4, many crops wont get planted or will be planted late. Under Alternative 5, they may get planted on time, but they run a higher risk of not

being harvested. It provides some variety on how to go bankrupt. Delayed harvest brings on extra costs, heavier wear and tear on equipment and harvest losses due to lodging and shattering, wildlife and wind and water damage. Harvest may be delayed until the ground freezes since ground drying conditions are almost always worse (humidity, temperature, less sunshine) in the fall than in the summer. Economic impact conclusions on interior drainage are incomplete and inaccurate. Flows are 77 percent higher at Kansas City (126,000 cfs for Alternative 5 versus 71,000 CFS for the no action alternative). Impacts to ground water, flap gates and pumping systems would be 77 percent more severe than with the no action alternative. The abbreviated analysis for interior drainage, such that it is, needs drastic recalibration.

Comment Text: Section 3.12.3.5 - Alternative 3 - Mechanical Construction Only We agree that the basic impacts of Alternative 3 are reduced, relative to the No Action alternative at the outset of the management actions. In general, Alternative 3 results in the least negative impacts. However, because it still contains a provision for adjusting flow regimen, and because of the broad negative impacts of higher flows, and the possibility that annual pulses can still be adopted under the adaptive management process, Alternative 3 can still be very damaging to stakeholders. But it strikes a better balance between promising species recovery actions and negative consequences. If it eliminated the potential for spring pulses it would be the only acceptable alternative. All economic conclusions and modeling on Alternative 3 are inaccurate and incomplete due to the failure to provide robust and accurate modeling and impact data on interior drainage. This alternative is unacceptable because no one knows what the impacts to NED, RED and OSE will be since the DEIS stipulates that economic analysis of the floodplain could not be completed. Translation of the impacts to the four sample sites to the rest of the floodplain was not even attempted and extrapolation from the four sites to other levee areas was not feasible since the hydraulics, hydrology and drainage varies between sites. However, given that no alternatives exist outside the six offered, we believe this alternative is the least unacceptable of the six alternatives.

Comment Text: Convoluted logic appears again. If all the acquired lands were previously in agricultural production, this means the amount of agricultural land that could be affected by flooding and the estimated agricultural losses in the lower river could be up to 3.0 percent less than the agricultural losses shown in Table 3-68. If it's not ag land any longer, the river can't flood ag land. That's just more evidence the culture that created the DEIS is anti-agriculture. They're not concerned about taking land out of production, damaging the economy, disrupting or dislocating families, eliminating jobs or threatening the food supply. The model apparently is believed to reduce some flood risk because of low summer flows. We agree that lower flows benefit flood risk, but caution that flood risk gains do not necessarily offset increased risks to navigation, public water supply, power generation or dredging.

Comment Text: Regional Economic Development This section blames all flooding on natural hydrologic cycles and fails to even acknowledge that the law that created the reservoirs came about because of the incredible damages caused by natural hydrologic cycles. There's a reason it's called the Flood Control Act of 1944. This section totally avoids mention that correct management of the reservoirs under the law limits the negative impacts of high water years. In fact, there is current litigation that charges mismanagement of the flood control capabilities of the reservoir system causes the flood damage. We believe natural events can occur that can overwhelm the reservoirs and levee systems. But to explicitly claim that flood damages are unrelated to management of the reservoir system is intellectually dishonest. This section then calls out 10 counties from South Dakota to Illinois that would have damage in excess of \$1 million. This follows the pattern of styling the DEIS in such a way as to trivialize the impacts of flooding. By calling out only 10 counties with damages in excess of \$1 million, the DEIS leaves the reader with the impression that these counties suffer the largest impacts from flooding but then only categorize the losses as over \$1 million. That's misleading. The damages could be in the tens or hundreds of millions but the DEIS does not call this out. Individual farms or businesses could easily have \$1 million in damages but the DEIS deftly, and we think deliberately, obfuscates that point. All economic conclusions and modeling on this alternative are inaccurate and incomplete due to the failure to provide robust and accurate modeling and impact data on interior drainage. Alternative 1 is unacceptable because no one knows what the impacts to NED, RED and OSE will be since the DEIS stipulates that economic analysis of the floodplain could not be completed. Translation of the impacts to the four sample sites to the rest of the floodplain was not even attempted and extrapolation from the four sites to other levee areas was not feasible since the hydraulics, hydrology and drainage varies between sites.

Comment Text: Section 3.12.3.3 - Alternative 1 - No Action Here, the DEIS states under NED: In addition, these impacts result from runoff events that occur downstream of the reservoir system, large upstream runoff events that result in evacuation of flood water from the reservoirs, or the combination of the two and not from the management actions under No Action. Once again, the impacts of the bimodal spring rise are not accounted for. Interior drainage impacts and flood risk impacts are not mentioned. This cannot be accurate. Table 3-63 - Summary of Damages for No Action The table shows average annual losses on the river below Gavins Point to be \$15,226,753. Using 2016 dollars, the average value of the production of corn and soybeans was roughly \$570/acre. The loss figure shown, divided by \$570, means crop loss on roughly 27,000 acres of farmland which is an annual average of losses on only 1.9 percent of the farmland in the floodplain below Gavins Point. We believe the assumptions for the modeling that developed this number need further calibration.

Comment Text: Table 3-61 - Environmental Consequences Relative to Flood Risk Management Changes to flow regimens are a part of each of the 6 alternatives and create the most significant impacts in 5 of the 6 alternatives, yet it is never mentioned in tables with Management Actions Common to All Alternatives. The table shows no NED, RED or OSE impacts. By never mentioning flow pulses we don't tabulate the damaging impacts to production and land values. Impacts from flow changes are neatly swept away. The table claims Alternative 2 has lower flood risk than the No Action alternative. We cannot find an Alternative 2 management action that reduces flood risk other than the low flow that occurs in summer months when significant rain events are not the norm. On the other hand, spring maximum flows during the proposed yearly spring rise in Kansas City are 16,000 CFS higher than the yearly artificial flow increases of the No Action alternative. How higher artificial flows during the rainy spring season create lower flood risk is counterintuitive and illogical. The table claims Alternative 3 has less flood risk. We would agree that since there are no spring rises for the first nine years, the flood risk is reduced. But we refer again to the lower flood risk in Alternative 2, even though it has spring pulses. If the model is delivering opposite results for the same actions, it might be wise to recalibrate the model. The table claims Alternative 4 modeling resulted in a -\$21 million to a \$48 million impact to NED. That's almost a \$70 million-dollar swing in impacts to the NED. We suggest either the model needs to be calibrated or Alternative 4 needs to be broken into two alternatives to reflect impacts more accurately. It could be that the model interprets the swing in years with no spring rise to a year with a massive spring rise to create massive flooding. That could explain some of the monumental differences, especially since the peak flow of 126,000 CFS at Kansas City puts the river over flood stage downstream from Kansas City. Any management action that deliberately floods any portion of the basin should be deemed unacceptable and be eliminated from the list of alternative actions. Alternative 5 shows the same maximum flows at Kansas City as Alternative 4, and the same four-year timetable as Alternative 4, yet Table 3-61 shows it as having a beneficial flood risk compared to the no action alternative. Alternative 5 constrains flow at 126,000 cfs, at Kansas City, 77 percent higher than the 71,000 cfs constraint in the no action alternative. The DEIS doesn't state how this is possible—one must infer it has something to do with a fall rise versus a spring rise. But, with flow constraints so much higher, the claim of flood risk reduction would seem to require further explanation, or a recalibration of the model. We would also note that the flow constraints are identical to Alternative 4 and Alternative 4 is characterized as having more flood risk than the No Action alternative. Timing and normal rainfall can impact flood risk, but a model that excludes out of the ordinary weather events from impacting the model seems risky in and of itself. Alternative 6 shows maximum flows at Kansas City in the 101,000-104,500 cfs range, running downstream flows to the action level, which at a minimum greatly impedes interior drainage. It is shown to have adverse flood risk compared to the no action alternative, which seems logical since the no action alternative has a 71,000 cfs restraint at Kansas City.

Comment Text: Section 3.12.2.1 - Population and Property at Risk In evaluating regional economic impacts, agriculture losses only included the change in market value of crop production In keeping with the agencies misstating negative impacts to agriculture, they were very careful to make sure they deducted any harvest costs that were not incurred because lost crops arent harvested. However, there was no inclusion of costs for rehabilitation of land, pumping costs, drainage infrastructure, repair to private levees or future yield losses due to damages to the land (sand and driftwood deposits, additional weed pressure, extra tillage requirements, etc.). Sometimes flooding causes land damage so severe the costs of rehabilitation are greater than the value of the land. Somehow those impacts are left out of the DEIS. The ongoing pattern of misstating impacts to agriculture could be construed to indicate an inherent bias in the DEIS.

Comment Text: 4. The lack of comprehensive interior drainage modeling and impact analysis means the economic impacts of the 6 alternatives are both understated and unknown. It is unacceptable that interior drainage impacts modeling and analysis was only conducted on four small areas of the floodplain. Given the pervasive reach of drainage, it is inconceivable that the modeling software was not updated. This methodology is entirely unacceptable and proves meaningful analysis of proposed management action on land use has not been performed. The title of this section is Flood Risk Management and Interior Drainage (emphasis added). Other elements are analyzed for the entire floodplain but interior drainage gets four small plots - one in Iowa and three in Missouri. The DEIS disregards interior drainage concerns by its failure to even conduct NED analysis in either the land use section of the DEIS or the abbreviated interior drainage portion of this section. The agencies failure to recognize the importance of, and the degree of debilitating impacts of artificially high river flows, is further evidence of the lack of depth and accuracy of the studies. Again, this omission is entirely unacceptable and it makes the DEIS incomplete and renders any appearance of actual NED, RED and OSE impacts improper and inaccurate. The failure to conduct thorough analysis of interior drainage is unfathomable and profoundly unacceptable.

Comment Text: The DEIS disregard of interior drainage concerns is further evidenced by the failure to conduct NED analysis in either the land use section of the DEIS or the abbreviated interior drainage portion of this section. The failure to acknowledge the importance and the degree of debilitating impacts of artificially high river flows is more evidence of the lack of depth and accuracy of the studies. The critical nature of interior drainage was brought forward frequently during MRRIC discussions. The DEIS appears to ignore the interior drainage information and the extensive concerns expressed by stakeholders during numerous MRRIC discussions. The most widespread and enduring economic impact of management actions on agriculture comes from the impedance of interior drainage. At the least, the exclusion of comprehensive modeling and analysis raises questions of whether those who managed the DEIS compilation process are qualified or competent. The Missouri River would not even exist if not for the need to drain excess water, yet the DEIS treats interior drainage as an annoying afterthought, unworthy of analysis or critical thought. The lack of comprehensive modeling and analysis of management impacts to interior drainage is egregious.

Comment Text: Flooding occurs sporadically. Interior drainage is an everyday requirement. While the risk of flooding increases with flow management actions, interior drainage is immediately impeded by each flow management action that affects river stage. High river stages cause high water groundwater levels and increase the time required for drainage to occur. The impacts range from ground water percolating upward through the soil profile to the closing of flap gates, holding back water from entering the river. Groundwater levels that do not percolate to the surface still reduce the ability of local rainfall to drain through the soil, keeping agricultural fields wet and delaying or even preventing crops from being planted. Landowners are damaged by the cumulative impacts of lower yields, total crop loss due to prevented planting and loss of land value because of the unpredictability of production. To the federal agencies, interior drainage is treated as an afterthought. To farmers in the floodplain, it is the most concerning and most economically damaging impact of all the management actions. During the MRRIC process several potential proxies for agriculture were discussed. After lengthy consideration, MRRIC and the agencies agreed that river stage was the best indicator of impacts to agriculture. This was not because of flooding, but rather because of impacts to interior drainage. River stage determines groundwater levels and whether gravity operated flap gates will function. The agriculture stakeholders agreed to this proxy because of the pervasive and wholly negative impacts of higher river stages on interior drainage. Given the magnitude of the impacts, the duration of the discussions and the attention given to reaching the proxy decision, the failure to conduct thorough analysis of interior drainage is unfathomable.

Comment Text: 1. Protecting human life and safety is paramount. We are concerned about the relaxing of flood control constraints in each of the DEIS alternatives, some by nearly as 80 percent to implement environmental flow experiments, with the potential to increase river stage by over nine feet in Omaha and five to six feet in St. Joseph. These potential stage increases do not take into account additional rainfall. Equally troublesome is the large degree of inaccuracy of predicted hydrologic conditions for more than six days in advance.

Comment Text: 3.10.2.5 - Alternative 2 - USFWS 2003 Biological Opinion Projected Actions Land acquisition in Alternative 2 is six times that of Alternative 1. As stated earlier, we believe the economic impacts of land acquisition listed in the DEIS are understated because of the effects of truncated economic modeling. Our concerns over modeling in general apply here as well. In addition, the lack of any mention of the impacts of the management actions that occur after the land is acquired is of serious concern and needs to be incorporated. The DEIS is substantially incomplete in scope and analysis. The inclusion of specific outcomes in terms of sales jobs and labor income are so specific they are misleading and are so un-researched they are inaccurate and unreliable. Because Alternative 2 results in multiple flow management actions, the negative impacts to all land uses listed in our comments on section 3.10.2.1 apply here, but to a much greater degree. In simple terms, the more often flow rises are implemented, the more negative the results to land use.

Comment Text: Section 3.10.2.1 - Impacts Assessment Methodology Unfortunately, the methodology employed in the DEIS is strictly limited to impacts of land acquisition. Weve already commented in detail on the truncated modeling used to assess these impacts and reiterate the impacts are substantially understated. The extraordinarily narrow focus of the DEIS on impacts to land use is unacceptable. Land acquisition is the only causal factor assessed in terms of Regional Economic Development (RED), National Economic Development (NED) and Other Social Effects (OSE). Even without one acre of land acquisition, management actions can severely impact land use. Management actions that change flow regimens can block interior drainage and cause late planting of crops and substantial yield reductions. In some years, it can prevent planting or harvest. Management actions that impede navigation increase transportation costs of critical and difficult to transport agricultural inputs. It can lead to increased traffic on public highways and wear and tear on that infrastructure, which in turn affects the suitability of various land uses. It can also increase loads on rail infrastructure and impact public safety. Management actions can drastically reduce the predictability of land use. Flow actions that impede interior drainage or increase flood risk can drastically impact land values, which in turn has a negative effect on the tax base of local governments. Management actions that impede dredging negatively impact both private and public construction costs. Management actions that impact local water supply and quality and cost substantially impact land use everywhere from major metropolitan to rural communities. Management actions that lead to lower levels of power generation or more expensive power generation significantly impact land use as well. Yet, none of these factors appear in the land use assessment methodology section of the DEIS -only land acquisition. The failure of the DEIS to account for, or even consider, such obvious impacts as these raise serious questions. Do the agencies charged with developing management actions simply lack understanding of the impacts of proposed actions? Do the agencies have the expertise and resources to conduct thorough studies? The concerns called out above have been mentioned repeatedly in the MRRIC environment. Is the culture within certain agencies such that impacts to land uses are always subrogated in deference to the perceived needs of listed species under the Endangered Species Act? Table 3-42 - Environmental Consequences Relative to Land Acquisition, 2016 Dollars Weve already commented on the accuracy of the economic impact predictions. However, we note again that the summary table impacts only lists land acquisition as the causal factor. A change in flows is common to all six alternatives. Yet in the portion of the table devoted to Management Actions Common to All Alternatives, Table 3-42 says there are no RED impacts, no OSE impacts and no other impacts. Increased flows increase the risk of and the severity of flooding and impact interior drainage. Explicitly claiming no impact of any kind in this table brings the credibility of the entire DEIS into question.

Comment Text: Section 3.10.1.1 - Land Use Patterns Agricultural land often surrounds developed lands and impacts from management actions often do not discriminate between the two. Impeded interior drainage problems, for example, can lead to structural issues with expensive grain handling facilities, storage structures and important community infrastructure. The river would not even exist if not for the drainage of water from the basin. We understand that land use classifications can help in the analysis of impacts, but caution that management actions can negatively impact all classifications.

Comment Text: It is telling that interior drainage impacts are not even modeled in Section 3.12, Flood Risk Management and Interior Drainage. We are told the software to evaluate impacts is not compatible with current computer operating systems, so modeling was not done. Apparently interior drainage has been given so little thought there was not even an attempt to update the software. Instead of modeling, four sites were selected as representative of the floodplain and a cursory impact study was performed. This methodology is entirely unacceptable and proves meaningful analysis of proposed management action on land use has not been performed. Further, the DEIS states: Extrapolation from the four sites to other levee areas was not feasible since the hydraulics, hydrology and drainage

varies between sites, Translation of damage-duration relationships between sites was not attempted and would require additional evaluation to provide a reasonable methodology and verify results.

Comment Text: There should be no change in regards to the length or intensity of flow events or pulses by the Corps. If changes are made that could very well result in the reduction and/or elimination of thousands of acres of agriculture lands. In addition, some levee districts do not have the ability to pump water, increasing the flood constraints will increase the susceptibility to flooding that those areas will face. The river changes greatly with rainstorm events in very short periods of time as it is, if the length or intensity of flow events increases, and then a rainstorm event happens there will not be any where for the water to go but to flood communities and farm grounds in its path.

Comment Text: Page xxviii, Executive Summary: "[U]nder Alternative 3, USACE would create ESH through mechanical means at an average rate of 391 acres per year in the Garrison, Fort Randall, and Gavins Point river reaches in years where construction is needed. This amount represents the acreage necessary to meet the bird habitat targets after accounting for available ESH resulting from System operations. Alternative 3 would also include the provision for a one-time spawning cue test release from Gavins Point Dam if the results of Level 1 studies during the first 9-10 years do not provide a clear answer on whether a spawning cue is important." **Comment:** The public, i.e. USACE, must assume liability for damages to private land and crops due to any alteration to

flood control structures. A revetment has the potential to do the most damage to private property. A revetment is a blanket of stone in the river bank ostensibly to protect the river bank from eroding and sloughing. Sloughing takes place because the footing of the river bank is washed away and the bank falls into the river for lack of support. Continued sloughing can destroy adjacent levees. If a revetment is breached, a chute will develop downstream as a result of the floodplain segment eroding all levee and drainage works until it discharges back into the river. Such a breach of revetment occurred during the 1993 flood on the property of the late Bill Lay in Howard County, Missouri. The entry of flood waters onto his property created a natural chute for the entire length of his property before discharging back into the river. Unfortunately, Bill Lay was unable to show a positive Benefit: Cost Ratio for USACE Title 84-99 flood damage repairs and was forced to sell his property. It is now the Lisbon Bottom Unit of 2014 acres at river mile L 214 to 218. Bank notching is the second most damaging type of project. Bank notching has been done on public property like the Big Muddy National Wildlife Refuge. Great lengths of the bank downstream (1,000 feet or more) can be washed away in the river's attempt to reconnect with the flood plain.

Comment Text: The NOAA Weather Prediction Center routinely verifies QPF performance. A score of 1 in the threat analysis indicates that the forecasted precipitation is accurate for the period analyzed. It is noteworthy that the months in which Alternatives 2, 4, 5, and 6 would be conducted do not have more than 50% accuracy for even a 0.5-inch rainfall event. Therefore, the Corps cannot rely on forecasts as the deciding factor in determining whether a flow event should be conducted. [Figure 1. National Weather Service, Weather Prediction Center, Quantitative Precipitation Forecast Verification.

<http://origin.wpc.ncep.noaa.gov/html/scorcomp.shtml>] Furthermore, flow events of the magnitude the Corps is contemplating frequently occur on the lower Missouri River. Alternatives 4 and 5 have flow events with a peak magnitude of 60,000 cfs in April and October. That is approximately 30,000 - 40,000 cfs more than the Corps would typically release based on Annual Operating Plan statistics (see Table 2 above and 2016-2017 Final Annual Operating Plan, Plate 3). Not only would such flow events raise the flood risk in the lower basin, but they are also completely unnecessary. Since the Missouri River Reservoir System became fully operational in 1968, there have been 487 occurrences in which a rise of 30,000 cfs or more has occurred at St. Joseph, Missouri, and 1,857 occurrences at Boonville, Missouri.

Comment Text: Flood control was one of the two main reasons the Missouri River Mainstem Reservoir System (System) was created, the other being navigation. As such, the Corps established flood control constraints, or "target flows," with the 1979 Master Manual. Flood control constraints are one of the techniques the Corps utilizes to prevent, or not contribute to, downstream flooding. Nevertheless, several of the alternatives in the DRAFT EIS would relax the existing flood control constraints some by almost 80 percent in support of environmental flows (Table 1). [Table 1. Flood control constraints under each of the alternatives in the Draft EIS. Note: The flood control constraints in Alternatives 2 and 6 are adjusted up or down based on runoff forecasts. The numbers listed here are from the Draft EIS.] For example, at St Joseph, Missouri, the magnitude of the rises proposed in Alternatives 4 and 5 could cause the river to rise 4.5 to 6 feet as a result of reservoir releases alone (Table 2). These alternatives would increase flood risk on the lower Missouri River by both intentionally increasing releases as well as decreasing the Corps' ability to respond to downstream high water events. [Table 2. Stage changes at St. Joseph due to increased System releases given average monthly flows. Data Sources: US Geological Survey, US Army Corps of Engineers.] The Corps must be keenly aware that a vast amount of large, unregulated flow downstream of Gavins Point Dam contributes to downstream flooding. Flood risk on the Missouri River is amplified given the travel time from Gavins Point to the Missouri state line. It takes approximately five days for water to travel from Gavins Point Dam to St Joseph, Missouri, and seven days for it to reach Boonville, Missouri. There are many instances in which rain events in the lower basin have developed over a five- to seven-day period that have caused the river to rise significantly without additional water from Gavins Point Dam. The Corps maintains it will be cognizant of forecasted rainfall prior to initiating a flow operation. But in the 2006 Master Manual (p. VII-30), the Corps states, "Experience has shown that predicted hydrologic conditions that could produce large rainfalls are only mildly accurate for periods 3 to 6 days in advance and are not accurate for periods more than 6 days in advance." It would be careless to implement these flow events in the face of the known risks associated with doing so.

Comment Text: In the DRAFT EIS, the current 2006 Master Manual is reflected as Alternative 1, or the No Action Alternative. While the 2006 Master Manual includes a bi-modal spring pulse, it left the flood control constraints undisturbed. The State of

Missouri has consistently opposed the bimodal spring rises in the current Master Manual given that it increases flood risk (see "Spring Rise Letter Pauley to McMahon 1-27-12" and "Governor Letter to Gen. McMahon RE Spring Rise 3-9-10" enclosed). Given the high frequency of flood events in Missouri, we have always expressed opposition to any proposed spring rise releases from Gavins Point Dam.

Comment Text: Flood control constraints at Omaha, Nebraska City, and Kansas City are critical to insuring that actions do not cause, or contribute to, downstream flooding. Alternatives 2, 4, 5, and 6 would relax flood control constraints by almost 80 percent. This is unacceptable to the State of Missouri as it would result in flooding on the lower river. For instance, the current flood control constraint at Kansas City is 71,000 cubic feet per second (cfs) whereas under Alternative 4 it would be increased to 126,000 cfs. This increase in the flood control constraint would cause flood stage to be exceeded at downstream locations such as Napoleon and Waverly even without additional runoff into the river. Relaxing the flood control constraints is contrary to the Corps' Congressional authority and the State of Missouri strongly opposes such an action (see "Flood Control" enclosure for farther comments).

Comment Text: It is clear, from recent flood history, that nature does provide an astonishing rate of floodplain connectivity- - probably, exceeding the minimum 20% chance of inundation for the minimum acreage specified in the USFWS planning guidance paper and the 2003 Biological Opinion targets. Many acres within the floodway that were flooded in 2011 were also flooded in 2010 and 2007, probably exceeding a 20% chance ACE or 5-year frequency. However, these targets are only analyzed for Alternative 2, and seem to be disregarded for Alternatives 3-6. Moreover, the geographic footprint for analyzing floodplain connectivity probably should be the HUC 6 watersheds contiguous to the Missouri River. But, we leave it to various agency scientists to ascertain whether the footprints used in this DEIS are appropriate and sufficient for the risks entailed.

Comment Text: We are very concerned in regard to proposed alternatives 1 thru 6 containing releases of various amounts that we feel would jeopardize interior drainage, seepage issues, and cause a negative effect to farm lands that our levee protects. To our understanding alternatives 5, 6 would be large releases from Gavens Point Dam in amounts of up to 60,000 cfs either in the spring or fall for periods up to 35 days are both completely unacceptable as to the problems of crop damages as to the inability to be able to farm these lands due to the increase in Missouri River levels. These releases coupled with any rainfall events that enter into the Missouri River basin via tributary run off plus local rainfall in our area would cause great harm to our levee district farms; landowners, tenants, residents in general. St. Joseph, Missouri river gauge has a stage of 17 ft. flood stage. It is our understanding that the Gavens Point release of 60,000 cfs would add approximately 5 to 5.5 ft. to the river level which would cause all of our gravity discharge gates to be closed causing impoundment of waters on the protected side of the main levee system. Carrying this scenario even further the high chances of flooding would be quite likely especially with the spring months The fall releases would be detrimental to harvesting of farm crops along with potential flooding associated with releases and any rainfall plus run off. Not only are farmlands affected by interior drainage, seepage, impounded waters but so are infrastructure namely homes, building sites, roads, highways, interstate plus intra state travel, utilities, lives are put in danger as flooding could be highly possible.

Comment Text: I stand opposed to the alternatives that add any additional releases from the dam systems into the Missouri River. We currently have difficulties with internal drainage and seepage when river levels run above 12 feet at the St. Joseph, Mo River gauge. Impounded waters and seepage cause the inability to plant our crops with mid April through June 1, being the planting window for our area. Also if we are unable to plant at these times the yields are reduced or possibly lands go unplanted due to these high water

events. Also if crops are timely planted and high water events come after planting crops are drowned out and or yields suffer. These farms are how I make my living, pay my bills, pay taxes. The alternatives that are proposed would be detrimental as to the additional releases from the dam at Gavens Point amounting to as much as 5 to 5 ½ ft. at St. Joseph, MO; I have been told. Local rainfall plus tributary run off flooding. Surely there must be a way to protect the habitat without placing undo problems on the farmer/stakeholder. Possible I here of being able to mechanically provide habitat and not alter flows from the dams. I could possibly give consideration to this plan as long as no increase in flows. Flood control should be number one in any consideration made.

Comment Text: The Corps hasn't completed their homework in the DEIS. Because impact studies have only been completed for four representative levee sites, I can't be confident in the risks of any of the alternatives. While I believe Alternative 3 provides a better balance between my farming operation and species recovery, I cannot support any flow modification in Alternative 3 or any of the other alternatives from going forward until economic and hydrologic modeling is completed for the entire floodplain. I have too much capital at risk each and every year to simply not know what the impacts to my operation will be. I deserve better from the Corps.

Comment Text: Major floods like those that occurred in 1993 in the downstream reaches of the Missouri River can be caused again by heavy local precipitation in the spring and fall. Since releases from the Gavins Point Dam take several days or more to reach downstream reaches of the river near cities such as St. Joseph, Kansas City, and Hermann, spring and fall rises are likely to cause flooding. For example, from the USGS data charts referenced below, one can see that flood waters can take up to three days to travel from St. Joseph to Hermann, Missouri.

Comment Text: As a farmer I rely on the Missouri River for my farm's water drainage! It is the main component of all our interior drainage systems which consists of field ditches, road ditches and creeks. Any slowing down of flow or restriction on the Missouri River affects all of the rest of this system. Your proposed flushes will create a high river event which will cause a situation where nothing else will drain or flow for miles inland from the river. This creates a situation where it is impossible to farm and raise a crop.

Comment Text: If you adopt at least three or four of these six plans and you have an event remotely close to 2011 or 2010, I mean, just remotely close, and then we have rain associated with a flood like '84 and '93 - - see, those were bad floods, but what made them really bad was all the five rivers that were trying to cram into them south of Omaha and north of Saint Joe. If you want a perfect storm, you not only have a couple bridges shut down, but our new bridge in Rulo probably would be - - the pilings would be unstable. My house would be gone, and it's been there since 1863. It would be gone. So the risk, just as you would take it off and you'd weigh out this stuff with the risk, what is the risk of what can go bad, and I haven't seen any of that in any of the data. And I haven't read all 6, 7,000 pages, but there needs to be a risk factor. There needs to be a Paragraph 6, and I haven't seen that.

Comment Text: Well, now here we are six years later talking about having a surge possibly twice a year. We're seven to ten days below the dams on the Missouri River. There's no way they can forecast the weather that far out, knowing what the rainfall is going to be in that time. And I feel that it's just a very dangerous situation to put us in. In our district alone, we have state highways. A flood event would split our school districts. Our availability for a hospital would be almost nil because we couldn't get to it, the closest one. We'd have to drive a half-hour to get to one instead of ten minutes. I just - - I'm not - - I don't know if there's anything that can be

done to help the pallid sturgeon and the birds, but I think we need to take care of the people first, consider what's going to happen to them and how it's going to affect their lives. For the State of Missouri, we cannot handle any type of surge.

Comment Text: And what concerns us directly now is the water level of the Missouri being as high as it is at this current moment. The lowering of the water will help; more sandbars for the birds, more longer drainage area from the dams for that sturgeon. So the elevation of the silt in the basins of these dams has created less storage for flood control in the lower and upper basin, and also has created, you know, less room for the fish and other animals. The main thing that we're concerned about is the flood control and keeping that in check along with the helping of the animals.

Comment Text: 3. Water releases described for many of the management alternatives provided for comment involve flows that will exceed the capacity of hydroelectric operations at each dam in South Dakota, meaning spillway or outlet work releases must occur.

All flow releases involve the downstream transport, or loss, of fish. While effects of flows associated with standard operation of the Missouri River dams for hydropower generation have been experienced for decades, effects of spillway and outlet work flows are not as well understood due to the low frequency of their occurrence. We recommend coordinated sampling efforts with South Dakota Game, Fish and Parks fisheries staff when spillway or outlet works flows are scheduled, to increase knowledge of how these releases affect fisheries resources.

Comment Text: As summarized in the Hydropower Environmental Consequences Analysis Technical Report, Alternative 3 provides the best economic impact result for hydropower generators. Iowa's consumer-owned electric utilities include rural electric cooperatives (REC's) and municipal utilities. These Iowa based utilities, along with approximately 300 other consumer-owned utilities in the Missouri River Basin, also have a critical dependence on the Missouri River. The Western Area Power Administration (WAPA) supplies them with electric power generated by six hydroelectric facilities located on the river. Changes in Missouri River operations can affect Iowa consumer-owned utilities that purchase power from WAPA. When WAPA cannot generate enough hydroelectric power to fulfill its contractually obligated agreements due to low water, WAPA must go to the open market and purchase electricity, often at higher costs, which are passed on directly to the consumer-owned utilities that receive electricity from WAPA.

Comment Text: On page 3-22 the channel capacity change due to aggradation of the Garrison Reach is described as the following: "At the time Garrison Dam was constructed, the open water channel capacity at the City of Bismarck, North Dakota, was approximately 90,000 cfs for a stage of 13 feet; however, aggradation decreased the channel capacity to approximately 50,000 cfs for the same stage by 1997 after 42 years of reservoir operation (USACE 2006a). This trend was temporarily decreased in 2011 when high flows scoured out the channel." According to this, channel capacity at the downstream end of the Garrison Reach has decreased about 40 percent. Implementing additional actions that exacerbate the aggradation will affect hydropower production over time. As sediment accumulates in the delta, releases will have to decrease in order to avoid exceeding channel capacity, especially during the winter when river ice cover causes a 5- to 7-foot stage increase.

Comment Text: While the DEIS provides scant discussion on the impacts to reliability from either the reduced hydroelectric or thermal generation output, there seems to have been no consideration of the cumulative impacts to the reliability of the power grid from the loss of both hydroelectric and thermal generation under the various alternatives. As the DEIS analyses show, lower or altered Missouri River flows can significantly reduce the output or value of hydroelectric generation and at the same time reduce the amount of thermal generation available. What was apparently not considered was the cumulative impact of the loss of both types of generation and the consequent impact on system reliability. The loss of significant amounts of baseload generation at the same time can seriously impact system reliability. It is not clear that sufficient transmission capacity exists to be able to purchase and import power from the market to replace the lost generation or that the market is liquid enough to absorb the necessary replacement power

purchases without significant price increases. It is imperative that the cumulative impact of changes in hydroelectric and thermal generation output on power system reliability be addressed in the final environmental impact statement to assess to what degree grid stability may be at risk under the various alternatives.

Comment Text: Mid-West appreciates the open and transparent way in which the Corps explained the processes for modeling the impacts on hydropower from the various alternatives. While the methodology employed by the Corps to estimate hydropower impacts is not unreasonable, Mid-West is concerned that the estimates of the hydropower impacts are likely understated. There are several reasons for our concern. First, to calculate the value of lost energy future estimates of power prices were derived from the Southwest Power Pool (SPP) market, which the Western Area Power Administration (WAPA) Upper Great Plains Region only joined in October 2015. The long-term projection is then driven by an Energy Information Administration forecast applied to the historical SPP prices. Less than two years of SPP data is an extremely short period of time from which to derive long-term power price estimates. Second, if there were a real and sufficiently large reduction in the hydroelectric output of the Missouri River projects, WAPA could change its contracts with the purchasing utilities to reduce WAPA's delivery obligation by the size of the reduction. The purchasing utilities would ultimately construct new resources rather than continuing to rely on market purchases forever. While market purchases may serve as a good short-term proxy, utilities would have to build new resources rather than rely on market purchases to protect against severe market fluctuations. The Corps's analysis appears to assume resource construction to replace the capacity of the reduced hydroelectric generation, but not for reduced energy output. Therefore, the long-term response to a significant reduction in the hydroelectric output of the Missouri River generating projects should be the construction of a new resource. Finally, while the DEIS provides some discussion of the potential impacts of changes in hydroelectric output on the production of ancillary services, quantitative analysis is necessary to determine the true impact. Ancillary services have become more important aspects of generation as huge amounts of intermittent renewable resources have been added to the system and as a consequence of a growing concern about the reliability of the power grid. While Mid-West believes that the Corps's approach to estimating the economic impact of the management alternatives on hydroelectric output and cost is generally reasonable, that analysis also likely underestimates the actual impact for the reasons stated above.

Comment Text: Section & Page Number: 3.14.2.5-10., p. 3-368 - 3-380 Comment: The distribution of overall effects on irrigation needs to be discussed in relation to "equity." The tables in current form are sufficient to outline the issue, but the discussion is uneven, mentioning the equity problems in some conclusions, and not in others. A major issue with North Dakota is that in options other than Alternative 3, North Dakota, and particularly Williams County, absorbs most of the relative losses. Alternatives 4 and 6 are particularly concerning, with losses ranging from 5% to 54%, and 7% to 25% in Emmons and Williams Counties, respectively. Where large negative changes are predicted, and particularly where there is a large imbalance of impact, the issue of equity, subsequent loss coverage and distribution, and compensation mechanisms or distribution of financial impact should be discussed in the document and considered in both the choice and the management of the choice of alternatives.

Comment Text: Section & Page Number: 3.14.2.4, p. 3-365, Table 3-137 Comment: The baseline (Alternative 1) case for Williams County (-\$8,8140,000) is strange. The footnote refers to losses under irrigated wheat production, which seems to indicate that the EIS is basing its economic baseline on irrigated wheat. An assumption that producers would consistently use a losing practice doesn't make sense. Is the assumption based on irrigated wheat, and if so, how was the wheat criterion chosen; and was it based on county crop averages? Irrigated acreage and crops grown are reported annually to the Office of the State Engineer on annual use forms (AUFs). The 2012 Irrigation AUFs for Williams County reported 446 Irrigated Acres of Wheat (1.93% of 2012 Irrigated Acres). The 2015 AUFs reported 921 Irrigated Acres of Wheat (4.19% of 2015 Irrigated Acres). There is very little wheat acreage irrigated in Williams County. Of greater concern would be irrigated corn (13,453 acres) or sugar beets (11,800 acres) in 2012. If the \$8.8 million loss was based on irrigated wheat, it is likely that the baseline (Alternative 1) farm income loss is unrealistically low, and if the same assumption is made in assessing projected losses, they may cause a low bias on loss estimates. Please re-examine the assumptions leading to the Alternative 1 figure and evaluate what the impact of those assumptions would have on the impact assessment values.

Comment Text: Section & Page Number: 3.14.2.1, p. 3-361 "No county in the research area relies exclusively on the Missouri River for irrigation. Counties were included in the impact analysis if a significant percentage of irrigated acres in the county used water from the Missouri River and if the alternatives showed noticeable changes in access to water." Comment: This statement implies that irrigators have other reliable sources of water. The Missouri River comprises over 90% of the surface water supply in North Dakota. Groundwater is sparse in western North Dakota and tributaries can be intermittent, especially during drought periods. And what constitutes a "significant percentage?" If half or even a quarter of the irrigators in Williams, Mercer, and Emmons Counties are negatively impacted - is that acceptable to the USACE? It is not acceptable to North Dakota.

Comment Text: Alternative 2 would also implement a bi-modal spring release from Gavins Point. In Alternative 2, the first pulse would begin on March 15 and would be as high as 31,000 cfs and the second pulse would start on May 1 and would be as high as

60,000 cfs. Both spring pulses would negatively impact navigation for roughly four weeks. Alternative 5 takes a different approach by mandating a flow release of up to 60,000 cfs out of Gavins Point in the fall [in the middle of harvest season] as often as every four years. If the river is already at high levels, which is often the case in the spring months, any increase in flows could cause negative impacts to navigation, agricultural, land owners, industries, and communities along the river. Releases in the 60,000 cfs range would most likely halt navigation due to high velocities. Towing companies operating on the Missouri River are concerned about releases from Gavins Point in May that exceed 50,000 cfs because they believe this amount of extra water has the potential to stop navigation on the Missouri River and cause elevated navigational risks on the mid-Mississippi River. The month of May is typically a time of high water on both the Missouri and Mississippi rivers without the addition of a spring pulse. If the May release is implemented without taking into consideration the natural flows, it would be a significant problem for navigation and other stakeholders in the entire region, including the farming community. Since the Missouri River often floods in the spring months, why would the Corps release more water and make the flooding worse?

Comment Text: Section 3.15.2.5 Alternative 2 - USFWS 2003 Biological Opinion Projected Actions Under Alternative 2, it is highly likely that the decreasing releases from the Gavins Point Dam in Alternative 2 during the summer months would drop flows below the Construction Reference Plane (CRP) levels and halt navigation. Navigation would once again become unreliable and the navigation community and the users of the commercial navigation system would suffer severe negative economic consequences. In this section, the DEIS states: Although split navigation seasons would adversely affect navigation NED, RED, and OSE under Alternative 2, the impacts would not be significant because the NED decreases in magnitude and percentage change is small; RED impacts would be negligible in the regional context; and air quality impacts for nitrogen oxide would not occur in non-attainment areas. This contradictory and flawed conclusion demonstrates a fundamental misunderstanding of Missouri River navigation by the study team. The navigation industry needs regulatory certainty in the form of consistent reliable flows.

Comment Text: Missouri River navigation relies on a reliable navigation channel measuring nine feet deep and 300 feet wide. The channel is provided by a combination of water from major tributaries and the release of water from the mainstem reservoirs. Industry uses the channel all year, but the March to April period is key for fertilizer shipments and the fall and early winter is important for grain export. Industry requires predictability and adequate flow support. Sudden changes in flow support can be economically impactful and even dangerous. Although shipments can be made at lower river levels, industry economics require that river levels be at intermediate service or greater to be profitable. These characteristics are not factored into the Missouri River navigation economic assessments conducted in the DRAFT EIS. In addition, the Corps did not present a summary table of navigation performance (service level and season length) among the alternatives for the 82-year dataset. These oversights need to be corrected in the Final EIS.

Comment Text: Stakeholders repeatedly asked the Corps to include water compelled rates in the DRAFT EIS analysis. Despite these requests, no such analysis was performed because it was deemed that "...Missouri River tonnage migrated to Arkansas River" and "...water-compelled railroad rates attributable to Missouri River commercial navigation seemed improbable" (Navigation Environmental Consequences Analysis Technical Report, p. 17). Barge transportation not only provides the most fuel-efficient method of moving tonnage (A barge can move 576 ton-miles per gallon of fuel.), but also is the safest (fewer accidents and spills) and least polluting mode (GAO Report 11-134, 2011). In 1998, while water-compelled benefits were valued at \$55.7 million for commodities moved on Missouri River, the value of Missouri River transportation availability was approximately \$10.4 million per year or \$8.43 per ton of commercial commodities shipped on the river (FAPRI-UMC Report, 2004).

Organization: Missouri Department of Natural Resources

Commenter: Carol S Comer **Page:** **Paragraph:**

Correspondence Id: 197 **Comment Id:** 645260 **Coder Name:** jgutierrez

Comment Text: Even though the Corps mentioned the amount of material moved on the Missouri River (Figure 3-59), there is no estimation or accounting for the value. For instance, the Corps' analysis does not distinguish between high-dollar commercial equipment (e.g., power plant equipment) and a bushel of corn. Between 2004 and 2015, AmerenUE has shipped replacement turbines and manufacturing equipment on the Missouri River which were valued at \$750 million (see John LaRandeau's presentation at St. Louis River Industry Club, February 2015). This information was not reflected in the DRAFT EIS. The turbines were shipped from France, and traveled nearly 1,300 miles on the Mississippi River and Missouri River to reach their destination. The Inland Waterway System is the only mode of transportation that can handle this type of large equipment. The Corps needs to properly account for the value of goods shipped on the Missouri River in the Final EIS.

Organization: Missouri Department of Natural Resources

Commenter: Carol S Comer **Page:** **Paragraph:**

Correspondence Id: 197 **Comment Id:** 645250 **Coder Name:** jgutierrez

Comment Text: Another important benefit of Missouri River navigation is the rate savings in other transportation modes resulting from the existence of commercial navigation as a shipping option. Water compelled rates occur when rail and truck transportation modes lower their rates to compete with barge rates. In other words, water compelled rates translate to savings to both producer and consumer. The Corps elected to not evaluate the benefit of water compelled rates in the DRAFT EIS. The State of Missouri requests that the Corps correct this shortcoming by including such analysis in the Final EIS.

Organization: Missouri Department of Natural Resources

Commenter: Carol S Comer **Page:** **Paragraph:**

Kept Private: No

Correspondence Id: 197 **Comment Id:** 645249 **Coder Name:** jgutierrez

Comment Text: It is critically important that the Corps recognize the Missouri River is an integral component of the Inland Waterway System. Beginning a few miles above St. Louis, Missouri and continuing to the confluence of the Ohio River, the bottleneck reach of the Mississippi River is heavily reliant on water from the Missouri River. The Missouri River has historically supplied 40 percent of the flow on average to the bottleneck reach of the Mississippi River. The Port of St. Louis is the third busiest (per tonnage) inland port in the United States. It's important to note that shipments do not arrive, or depart, unless the bottleneck reach has sufficient flow. Additionally, shipments to or from the Illinois River or the Upper Mississippi River, which must also transit the

Middle Mississippi River, are affected by the flows coming out of the Missouri River. Shippers have no choice but to load barges lighter when river stages begin to fall. Even though the Corps produced estimates of how much tonnage would be impacted by each of the alternatives in the DRAFT EIS, the Corps failed to analyze the economic impact of such actions. The State of Missouri requests that the Corps correct this shortcoming in the Final EIS.

Comment Text: Under the Flood Control Act of 1944, Congress authorized the Corps to govern the U.S. waterways. Additionally, this act required the Corps to prioritize flood control and navigation as dominant functions of its authority. Though the responsibilities of the Corps have increased over time with additional directives from Congress, namely those to assist in protecting endangered species, the new obligations have not diminished the original priorities. While the courts have noted the difficulty in balancing these varied interests, case law is clear that endangered species do not get to take precedence to the detriment of flood control and navigation. Thus, while it is a painstaking task, it is nonetheless imperative the Corps find a fair balance for these complex issues. AWO understands the difficult nature of this endeavor and is confident the recovery of the pallid sturgeon, least tern and piping plover can be achieved without negatively impacting the efficient movement of commerce on the Missouri and Mississippi rivers.

Comment Text: Table 3-173 shows that for Alternative 5, years with full or partial releases do not have an impact on navigation benefits. The DEIS indicates that this makes sense since the releases would be in the fall when the navigation season is almost complete. This is a false assumption because it does not account for the harvest season and the increased export market on both the Missouri and Mississippi rivers during the fall. This flawed assumption results in inaccurate and understated impacts of Alternative 5 on navigation. The conclusion illustrated in Table 3-173 also falsely assumes that navigation on the Missouri River ceases when the navigation season (flow support) officially ends. This is not the case as navigation continues on the river after the end of the navigation season as long as there is a reliable channel and weather conditions permit. In fact, several barge companies were operating on the Missouri River in February of 2017 due to favorable weather and reliable flows. Once again, this false assumption

results in understated impacts of Alternative 5 on navigation as well as understated total economic benefits of Missouri River navigation.

Organization: The American Waterways Operators

Commenter: Justin L Lampert **Page:** **Paragraph:**

Kept Private: No

Correspondence Id: 168 **Comment Id:** 645176 **Coder Name:** jgutierrez

Comment Text: In several sections, the Corps models include faulty assumptions and omit critical data that cause the output results to be misleading and inaccurate. For example, the modeling does not account for the impacts of navigation on transportation costs and agricultural profitability. Low summer flows and flood events intensified by unreliable releases from Gavins Point can have serious negative impacts on transportation. Since these interconnected economic impacts are not addressed, the overall economic impacts of the management actions for all alternatives are substantially understated.

Organization: The American Waterways Operators

Correspondence Id: 168 **Comment Id:** 645175 **Coder Name:** jgutierrez

Comment Text: Another problem with the Corps economic modeling used in the DEIS is that it consistently relies on old, outdated and inaccurate information to calculate the impacts. For example, to estimate the impacts in the NED account for navigation, the variables to estimate changes in transportation saving and repair, replacement and rehabilitation costs (R, R, & R) were based on data from the Master Water Control Manual Missouri River Review and Update Study, Volume 6A-R: Economic Studies Navigation Economics (Revised) (1998). This study is almost twenty years old and does not reflect the recent increase in barge activity on the Missouri River. In addition to relying on this outdated study, the Corps did not consult with members of the towing industry or its customers to obtain feedback on how to calculate transportation savings and R, R, & R costs in its NED analysis. Furthermore, the RED evaluation also appears to be insufficient and lacking in data from the tugboat, towboat and barge industry.

Organization: The American Waterways Operators

Commenter: Justin L Lampert **Page:** **Paragraph:**

Correspondence Id: 168 **Comment Id:** 645174 **Coder Name:** jgutierrez

Comment Text: Finally, the use of the 82-year period-of-record is flawed because it includes years when the federal government mandated artificial regulatory actions that greatly diminished the presence of navigation on the Missouri River. This, in turn, results in a significant understatement of the navigation benefits on the Missouri River. As stated previously, the low summer flows on the Missouri River in the early 2000s caused navigation to virtually disappear. Several towing companies went out of business during this time due to the lack of consistent reliable flows on the Missouri River. A few years later, the Corps implemented a large spring rise to serve as a spawning cue for the pallid sturgeon. This second artificial federal action further discouraged navigation on the river due to reliability concerns. In fact, navigation on the Missouri River did not begin to recover until recent years when the Corps provided reliable flows. Yet, despite these artificial government actions that negatively impacted navigation during these years, the DEIS still includes these years in the period-of-record for the modeling. These years should be excluded from the modeling, otherwise the benefits of navigation are substantially understated in the DEIS.

Comment Text: Alternatives 4 and 5 create problems for navigation by doubling the releases from Gavins Point for a period of 35 days. Alternative 4 would implement a flow release of up to 60,000 cfs out of the Gavins Point Dam on April 1 as often as every four years. Alternative 6 would implement a bimodal pulse (release) in March and May. Based on the Corps modeling, the Gavins Point releases during the March release would be between 39-61,000 cfs. Gavins Point releases during the May release would range from 50-67,000 cfs. These excessive flows would increase safety risks for crews, forcing towing companies to decrease tow sizes, travel only during daylight hours or completely stop. These safety actions would vastly increase costs to the nations transportation system.

Comment Text: Perhaps the most interesting component of the DEIS conclusions on the impacts of Alternative 2 on Missouri River navigation is that these conclusions are contradictory. The passage above from section 3.15.2.5 states that the impacts of Alternative 2 would not be significant because the NED decreases in magnitude and percentage change is small; RED impacts would be negligible. However, Section 3.15.2.11-Cumulative Impacts-Missouri River Navigation concludes that navigation could experience adverse impacts from low-summer flows. This section of the DEIS states the following: Adverse impacts could result in the reduction of the navigation season length for years with the low summer flow, and the potential reduction in service level provided that could occur in the years with the spawning cue pulse. When combined with other past, present and reasonably foreseeable future actions, the cumulative impacts on navigation associated with Alternative 2 would result in a large reduction in navigation benefits. The majority of the relatively large, long-term adverse impacts would be caused by the low summer flow which would shorten the navigation season and prohibit navigation during the important months of the year. While shippers may be able to plan around the low summer flow period, the reliability of the of the Missouri River would be reduced and shippers would begin to transition to other modes of transportation. Over time as more shippers switch to other modes, the overall navigation benefits on the Missouri River would be largely reduced.: The conclusions in the DEIS on the cumulative impacts of Alternative 2 on Missouri River navigation are severe and not one bit negligible contrary to the earlier conclusions in Section 3.15.2.5 on the impacts of Alternative 2 on Missouri River navigation. Why does the DEIS include contradictory conclusions regarding the impacts of Alternative 2 on Missouri River navigation? Why are these contradictory conclusions not explained in the DEIS? The potential negative impacts of Alternatives 4, 5 and 6 on Missouri River navigation are grave.

Comment Text: It is highly likely that the decreasing releases from the Gavins Point Dam in Alternative 2 during the summer months would drop flows below the Construction Reference Plane levels and halt navigation. Navigation would once again become unreliable and the users of the commercial navigation system would suffer severe negative economic consequences. The DEIS Section 3.15-Navigation concludes the following regarding Alternative 2: Although split navigation seasons would adversely affect navigation NED [National Economic Development], RED [Regional Economic Development], and OSE [Other Social Effects] under Alternative 2, the impacts would not be significant because the NED decreases in magnitude and percentage change is small; RED impacts would be negligible in the regional context; and air quality impacts for nitrogen oxide would not occur in non-attainment areas. This contradictory and flawed conclusion demonstrates a fundamental ignorance of Missouri River navigation and the navigation industry. To thrive all businesses require regulatory certainty, for the towing industry that includes reliable flows.

Comment Text: The DEIS states the following regarding the one-time spawning cue test: The one-time spawning cue test (level 2) release that might be implemented under Alternatives 3,4, and 5 was not included in the hydrological modeling for these alternatives because of the uncertainty of the hydrological conditions that would be present if implemented. Hydrologic modeling for Alternative 6 simulates reoccurring implementation (level 3) of this spawning cue over a wide range of hydrological conditions in the period of record. Therefore, the impacts from the potential implementation of a one-time spawning cue test would be bound by the range of impacts described for individual releases under Alternative 6. If a one-time flow test is eventually implemented in the future, this federal action must undergo comprehensive economic and hydrological modeling to assess its impacts on Congressionally-authorized purposes of the system, especially the primary purposes, navigation and flood control. The modeling for this release over the range of hydrological conditions for Alternative 6 is not sufficient to address future hydrological conditions, weather patterns and the possible impacts of climate change.

Comment Text: As previously mentioned, the "navigable portion of the mainstem of the Missouri River stretches 735 miles, from Sioux City, IA at the northern reach to St. Louis, Missouri, in the south,"¹⁷² or about 31 % of the total length of the river. ¹⁷³ Due to the relatively large portion of the river that is used for navigation, it is reasonable to assume that mechanical habitat construction, such as early life stage pallid sturgeon habitat and ESH, may affect navigation in some form. However, the Corps simultaneously argues that there are no impacts from mechanical habitat construction in any of the 6 alternatives, but that if ESH were to impact navigation, the ESH would be deconstructed. The MRRMP-EIS describes the relationship between early life stage pallid sturgeon habitat and navigation, writing in each alternative's section as follows: Generally, these actions involve physical manipulation of the river bed, bank, and/or channel structures. Despite the potential to affect channel structures, these actions are assessed as not likely to impact navigation because each project will be designed to not impact other authorized purposes including navigation. Prior to any site-specific construction project, monitoring will be conducted to detect any issues such as shoaling in the navigation channel. If issues are detected then adjustments will be made to restore the authorized 9 foot deep by 300-foot wide navigation channel. ¹⁷⁴ As a result, navigation is given priority over ESH construction because the design of the habitat itself is supposed to prevent any impacts to navigation. But the Corps states that if effects to navigation do occur, then the habitat construction would be undone to return to the original use of the channel. This is significant because it means that potentially far less early life stage habitat could be created than each of the alternatives suggest, and that pallid sturgeon goals may not be met. The discussion of mechanical habitat construction in the navigation section also highlights the effects of ESH on the navigation industry. As it did with the early life stage habitat, the Corps claims that ESH will not have an impact on navigation. More specifically, the Corps claims that each alternative's ESH construction "would not occur in the navigable portion of the river so no impacts to navigation would occur."¹⁷⁵ It is unclear how this would be implemented because the USFWS has outlined a goal of 80 acres of ESH per river mile below Gavins Point Dam, all of which is within the navigable portion of the river. ¹⁷⁶ It is unlikely that there would be no ESH construction within that portion of the river given the species goals. But even if the constructed habitat would have some incidental impact on navigation, the Corps should not abandon this management action because it is essential to meet species goals.

Comment Text: Alternative 5: First: "Alternative 5 would have a relatively small adverse impact on navigation benefits compared to Alternative I because it could reduce the annual NED by \$0.006 million, approximately 1 percent of annual NED benefits." ¹⁶⁸ Last:

"Impacts to navigation under Alternative 5 are not anticipated to be significant because the overall impact is expected to be relatively small."169 Alternative 5 is also cast in a negative light by first introducing it as having adverse impacts to the navigation industry, then concluding that those same impacts would not be significant. It reinforces the positive impacts outlined in Alternative 3 even though they are still small. Alternative 6: First: "Modeling indicates a relatively large adverse impact would occur to navigation under Alternative 6 by reducing annual NED by \$0.042 million, approximately six percent of annual NED benefits."170 Last: "Although the spawning cue releases would shorten navigation seasons and adversely affect navigation NED, RED, and OSE under Alternative 6, the impacts would not be significant because the NED decrease in magnitude and percentage change is small; RED impacts would be negligible in the regional context; and air quality impacts for nitrogen oxide would not occur in non-attainment areas."171 Alternative 6 shows the largest impact on navigation, yet it is still ultimately considered to have no significant impact on navigation. The way that this is communicated effectively puts a negative bias on Alternative 6 because there is a large adverse impact in the first sentence. It is hard to believe that anything with a large impact would not be considered significant. Each of the alternatives begins their concluding paragraph with a sentence that says the alternative is negative for Alternatives 2, 4, 5, and 6 or positive for Alternative 3. Each Alternative's conclusion then ends with a sentence saying that those impacts are not significant. However, it is hard to believe that this conflicting information is accurate because each adverse impact is either slightly adverse, adverse, or largely adverse. In addition, the fact that Alternative 3 is the only alternative with positive impacts shows the bias towards that alternative, furthering demonstrating an unreasonable range of alternatives.

Comment Text: Alternative 3: First: "In comparison to Alternative 1, Alternative 3 would have a slightly beneficial impact on navigation compared to Alternative 1 because it could improve the annual NED by \$0.002 million and increase average annual jobs of 3 and \$33 K in labor income although there would be negligible impacts to regional economic conditions."164 Last: "Overall, Alternative 3 would not have significant impacts to navigation because the analysis indicates a slight relative benefit would occur in comparison to Alternative 1."165 Just as with Alternative 2, the two sentences above convey conflicting meanings. The first sentence gives the impression that Alternative 3 is beneficial for navigation, whereas the last sentence reveals that the impacts of Alternative 3 on navigation are not significant. These messages are conflicting and show a bias favoring Alternative 3. Alternative 4: First: "In comparison to Alternative 1, Alternative 4 would have an adverse impact on navigation benefits by decreasing the annual NED by \$0.045 million, approximately six percent of annual NED benefits."166 Last: "Although the spring releases would shorten navigation seasons and adversely affect navigation NED, RED, and OSE under Alternative 4, the impacts would not be significant because the NED decrease in magnitude and percentage change is small; RED impacts would be negligible in the regional context; and air quality

impacts for nitrogen oxide would not occur in non-attainment areas." 167 These sentences are almost the same as those written for Alternative 2. Thus, they exaggerate the adverse impacts of this alternative. This makes Alternative 3 look like the best choice among the alternatives for the navigation industry.

Comment Text: 3. The navigation analysis is improperly designed to favor the selection of Alternative 3. The MRRMP-EIS shows conflicting results among the alternatives as they pertain to navigation impacts. Each conclusion is summarized in Table 6 but explained in more detail here. The Corps first concludes that "impacts to navigation under Alternative 1 are not anticipated to be significant."161 Therefore, the conclusions within the other alternatives are basically the same as what they would be if they had not been compared to Alternative I. Each alternative after Alternative I has conflicting claims between the first and last sentences of their concluding paragraphs. The first and last sentences of each concluding paragraph are outlined below for each alternative: Alternative 2: First: "In comparison to Alternative 1, Alternative 2 would have an adverse impact to navigation by reducing NED by \$0.028 million annually, approximately four percent of annual NED benefits, due to the low summer flow navigation season."162 Last: "Although split navigation seasons would adversely affect navigation NED, RED, and OSE under Alternative 2, the impacts would not be significant because the NED decrease in magnitude and percentage change is small; RED impacts would be negligible in the regional context; and air quality impacts for nitrogen oxide would not occur in nonattainment areas." 163 These two sentences are confusing and conflicting because the first sentence states that there would be an adverse impact to navigation, but the last sentence states that those impacts are not significant. This inconsistent and confusing language puts a focus on the fact that the small impacts from Alternative 2 are adverse and creates a negative bias in how Alternative 2 is understood even if the impacts are not significant.

Comment Text: Like the discussion of Alternative 4, the discussion of Alternative 5 shows differing results in the navigation and sand and gravel sections. Table 6 shows a 0.5% difference in NED between Alternative 5 and Alternative 1, then considers it a negligible impact for sand and gravel dredging. However, as shown in Table 7, "Alternative 5 would have a relatively small adverse impact on navigation benefits compared to Alternative 1 because it could reduce the annual NED by \$0.006 million, approximately 1

percent of annual NED benefits."159 While these percentage differences are not as significant as some of the other alternatives, they show conflicting results (negligible impact versus a small adverse impact). For the last alternative, Alternative 6, there is also a discrepancy between the two NED values found in each section. The sand and gravel industry section shows a negligible 0.4% difference in the NED between Alternative 6 and Alternative 1, as indicated in Table 6. Table 7 below, summarizing the navigation section, shows that "a relatively large adverse impact would occur to navigation under Alternative 6 by reducing annual NED by \$0.042 million, approximately six percent of annual NED benefits."160 Once again, the two sections reach contradictory conclusions despite the similarity of the activities. Table 8 below compares the percentage difference in NED for each alternative relative to No Action for each industry. Comment Text: Regarding Alternative 3, Table 6 shows that the NED difference for the sand and gravel industry differs from Alternative 1 by 0.1 %. Table 7 below, which outlines the impacts of each alternative on navigation compared to Alternative 1, shows a difference of \$0.002 million in NED from Alternative 1, a difference of 0.28%. While the percentage values for Alternative 3 in Tables 6 and 7 are similar (0.1 % difference on Table 6 compared to 0.28%, on Table 7), the results are presented in conflicting manners. According to the section on sand and gravel dredging, "any NED impacts to the commercial sand and gravel dredging industry under Alternative 3 would be negligible due to the measurable but very small percentage change from Alternative 1."155 However, the navigation section states that "Alternative 3 would have a slightly beneficial impact on navigation compared to Alternative 1,"156 even though the values differ by less than two-tenths of a percent. How can there be a negligible impact on one industry (sand and gravel dredging) but a benefit impact to the other industry (navigation) where the two are extremely similar? [Table 7: Impacts to Navigation Relative to No Action] The same factors are at work in the comparison of Alternatives 4 through 6 in the navigation and sand and gravel sections. The discussion of Alternative 4 in the two sections is like that of Alternative 2. In Table 6, sand and gravel dredging shows a -0.2% "negligible" difference between Alternative 4 and Alternative 1, while in Table 7, navigation shows an "adverse" difference of approximately 6%, "decreasing the annual NED by \$0.045 million. 157 The navigation section further contradicts the sand and gravel section by stating that "relatively large adverse effects to commercial sand dredging from shortened navigation seasons would occur in some years." 158 Again, it is important to note that "commercial sand dredging" differs from commercial navigation, which does not include the sand and gravel industry's barge traffic.

Comment Text: Both the navigation and sand and gravel dredging sections of the MRRMP-EIS include a breakdown of how each alternative would impact the industries relative to the No Action Alternative. The conclusions reached for each of the alternatives in each of the industries are confusing and self-contradictory, rendering the analysis virtually useless. Below, Tables 6 and 7 show the impacts of each alternative on the navigation and sand and gravel dredging industries. Table 6 clearly shows that there are no significant impacts to the sand and gravel dredging industry from any of the alternatives. The only quantifiable difference between the analyses of each of the alternatives can be found in their National Economic Development (NED) values. Each alternative is less than 1 % different from the No Action Alternative, which itself allegedly has negligible impacts on sand and gravel dredging. [Table 6: Impacts to Sand and Gravel Dredging Relative to No Action] However, when the section on sand and gravel dredging impacts is compared to the section on navigation impacts, there are many contradictions. The types of commodities that travel along the Missouri River are broken "into four broad categories . . . commercial sand and gravel, waterway improvement materials, other commercial cargo, and oversized goods."150 Of these four categories, "since 2000, sand and gravel has represented greater than 85 percent of the commodities shipped on the Missouri River."151 However, there is a difference between "commercial sand and gravel" and "other commercial cargo" navigation on the river. The sand and gravel navigation was already considered in its own section, so it should be excluded from the analysis in the navigation section. Since the MRRMP-EIS treats the majority of navigation on the Missouri River as sand and gravel dredging, one would think that the navigation sections of the MRRMP-EIS would reach a conclusion similar to that reached in the sections on sand and gravel dredging - that the impact is negligible. Under the sand and gravel dredging section, a NED value was calculated "based on impacts related to transportation of material" where one of the values was "navigation transportation savings."152 Under the navigation portion, a NED value was also "calculated by subtracting the change in non-routine repair, replacement, and rehabilitation (R, R, & R) costs from the transportation savings."153 By using the same metrics to calculate each of the NED values, both industries should show a substantially similar impact among the alternatives. While the No Action Alternative seems to have similar results for both navigation sand and gravel dredging, the other alternatives have conflicting NED values. Table 6 above shows that the Corps has determined that the NED effects for Alternative 2 when compared to No Action are negligible with only a 0.5% difference. However, the analysis of NED effects found in the navigation section reaches a different conclusion about sand and gravel dredging: Alternative 2 would have an adverse impact to navigation by reducing NED by \$0.028 million annually, approximately four percent of annual NED benefits, due to the low summer flow reducing navigation season. There would be relatively large adverse effects to commercial sand dredging jobs and income in years with low summer flows, but negligible impacts to regional economic conditions. 154 The difference between the two NED analyses on the impacts of Alternative 2 to the two industries is unexplained because the same factors were used to calculate both and a clear majority of materials currently transported on the Missouri River is performed by the sand and gravel industry (typically transporting its products fewer than ten miles each trip).

Comment Text: 1. The importance of sand and gravel dredging is overstated because it is not an authorized use of the Missouri River. The primary use of dredged sand and gravel is for the "construction industry, including road and highway construction," and "the Missouri Department of Transportation is one of the largest customers of sand from the Missouri River."¹⁴¹ Dredging operations are centered around the sand and gravel companies' on-shore processing plants, typically taking place no more than 7- 10 miles upstream and no more than 3- 9 miles downstream from a plant. ¹⁴² The average production volume of sand and gravel dredged from the Missouri River between the years 2010 and 2015 was 3,763,577 tons. ¹⁴³ Figure 1 below shows that in recent years, sand and gravel barge traffic volume has fallen below the five million ton goal for navigation on the Missouri River, even when combined with commercial navigation. In addition, it shows a large difference between commercial navigation and sand and gravel dredging. This difference shows that actual commercial navigation on the river is negligible in comparison to sand and gravel dredging, and that the navigation statistics reported in the MRRMP-EIS rely mostly on sand and gravel barge traffic: ¹⁴⁴ [Traffic graphic] The sand and gravel dredging industry is regulated through permits, and "every five years the dredgers must reapply for Department of the Army permits."¹⁴⁵ In 2003 and 2004, the Corps "received 10 applications from commercial sand and gravel companies for permits to extract sand and gravel from the [Lower Missouri River]. In August 2007, the USACE Kansas City District authorized four applicants to continue existing dredging operations."¹⁴⁶ Thus the Missouri River dredging industry is relatively small. But despite its size, the industry manages to be quite environmentally destructive: "the reaches of the river most degraded- Kansas City, Jefferson City, and St. Charles- were found to coincide with areas where commercial sand and gravel dredging was the greatest."¹⁴⁷ The dredging industry may even have its own adverse impact on the species because "dredging and associated river bed degradation could be contributing to impacts on habitats of federally listed threatened or endangered species."¹⁴⁸ When discussing the impacts that the ESH construction of Alternative 2 would have on the sand and gravel dredging, the Corps erroneously states "each project will be designed to not impact other authorized purposes including sand and gravel dredging as described in Section 2.5.3.1."¹⁴⁹ But even if the impacts were stated consistently throughout the MRRMP-EIS, sand and gravel dredging is not a congressionally authorized use of the Missouri River and should afford no special protection in the development of alternatives. Therefore, the sand and gravel dredging industry should not be given undue consideration in the MRRMP-EIS. If anything, reducing dredging activity would seem to accrue benefits to species protection.

Comment Text: D. The MRRMP-EIS Overstates Impacts to Navigation and Sand and Gravel Dredging. The Corps "operates the System to serve eight congressionally authorized project purposes of flood control, navigation, irrigation, hydropower, water supply, water quality, recreation, and fish and wildlife." 138 The Missouri River is also used for sand and gravel dredging, which is not statutorily authorized. Since navigation is one of the System's eight authorized purposes, 139 an analysis of the Alternatives' impacts on navigation is a permissible consideration. However, the Corps overstates those impacts where it analyzes sand and gravel dredging under the topic of navigation as well as under its own category, particularly since the conclusions of the MRRMP-EIS in the section on sand and gravel dredging conflict with the conclusions in the navigation section. Navigation impacts are also overstated due to the low volume of actual commercial navigation on the Missouri River. Figure 1 below, which is provided in the MRRMP-EIS, shows that the commercial barge traffic volume on the Missouri River falls far below the navigation target of five million tons of commercial barge traffic. 140 In addition, the scale and weight of navigation and sand and gravel dredging are misleadingly inconsistent. Furthermore, the Corps overstates impacts to the sand and gravel dredging industry because it is not a congressionally authorized use of the river.

Comment Text: The MLDDA is opposed to the low summer flows and spring pulses in the default plan in the 2003 Amended Biological Opinion and the vestiges of this plan in Alternative 2-U.S. Fish and Wildlife Service 2003 Biological Opinion Projected Actions in the MRRMP DEIS. Another plan with low summer flows could serve to once again eliminate barge transportation on the Missouri River. A channel of appropriate depth must be maintained for reliable barge transportation, and such a channel can be permanently damaged by siltation and reduced scouring action due to a prolonged loss of adequate flow. As a result, alternative shipping costs would increase and the net price to farmers would decrease. Farmers would also pay higher prices for agricultural inputs as a result of the loss of water compelled rates (reduced competition) for long haul truck and rail transportation. The loss of barge transportation would serve to escalate transportation costs to a far greater extent than that represented by the increased demand placed on other modes of transportation by the tonnage that would have been carried by barge.

Comment Text: Conversely, summer low flow provisions in Alternative 2 would cause extreme harm to the Missouri River's navigation industry; one that's been on the rise due to increased water supply and reliability. The Missouri River can contribute over 70 percent to the flow of the middle Mississippi River during times of drought. The harmful effects of low summer flow to our nation's economy must be taken into consideration and the Corps should remove this proposed flow option. Navigation is critical to moving harvested crops to market and inputs up river. With increased supplies of corn we must have every transportation option available. Waterways continue to be the most efficient and environmentally friendly mode of moving grain to market. Missouri River management should support those goals.

Comment Text: The Missouri River has been a staple in the past and more important than ever in moving large quantities of corn, soybeans, agriculture fertilizer, rock and gravel, sand, cement, fabricated steel, and large industrial equipment and machinery. Military equipment from National Guard facilities throughout the State of Missouri could also be moved by barge. This mode of transportation is by far the most cost effective and efficient method of moving these products long distances. It is imperative the USACE reconsider the impact of the proposed plan and amend it so as to make real economic growth possible by having a minimum navigable draft level of nine feet for at least eight months, preferably nine months of each year. This is very important. Relationships have been developed with both foreign and domestic business alliances. The newly widened Panama Canal offers us business opportunities we have never been able to pursue until now. Customers are wanting to buy products from our region of the country. We must be able to ship these large quantities cost effectively and in a timely manner. Barge transportation is the only viable solution to this new demand.

Comment Text: Since the closure of Garrison Dam over 60 years ago, over 570,000 acre-feet of sediment have been deposited in the upper portions of Lake Sakakawea (USACE 2014). Simply dewatering this depositional zone would not undo decades of sedimentation and restore a naturally functioning river. Aside from the questionable benefits to larval pallid sturgeon, significant drawdown of Lake Sakakawea would have devastating consequences to the fishery, recreation and local economies. Sixty years of fisheries research by NDGFD has confirmed that maintaining an adequate water level (absolute minimum of 1825 msl) and having a rising pool during the spring spawning and egg incubation period are critical for maintaining the number one most used fishery in North Dakota - Lake Sakakawea.

Comment Text: 2. South Dakota and Nebraska jointly manage the paddlefish population below Gavins Point Dam. A paddlefish snagging season is conducted during the month of October each year. Restrictions on areas where boats can fish are in place if water is flowing over the dam spillway. Initiating increased flows on October 17th will affect the area of river below the dam open to

paddlefish snaggers, reducing opportunity and potentially paddlefish harvest. 3. High reservoir releases will likely have similar impacts as the spring release on the Lewis and Clark Lake walleye population. By late fall, abundance of young walleye is highest in the downstream section of the lake, and fall releases of 60,000 cfs would likely result in entrainment of a large percentage of these newly hatched walleye. The actual effect of such a release is hard to estimate because a fall pulse of that magnitude is rarely seen in natural systems, and current reservoir management prescribes for much lower releases in the fall. Although the impact of a fall release would likely be lower than of the spring alternative due to increased size of young walleye, both alternatives would result in decreased walleye abundance in Lewis and Clark Lake.

Comment Text: The Corps has greatly underestimated recreation on the lower Missouri River. The data used in the DRAFT EIS is from 2005 whereas public participation has dramatically increased since that time. For example, the Hartsburg Pumpkin Festival, Katy Trail Bike Ride, Missouri River 340, and Race to the Dome are just a few of many recreation activities that occur in the lower Missouri River but are not quantified or considered in the analysis. Furthermore, the Corps used the antiquated Unit Day Value approach to evaluate recreation. Unit day value method is an old method used to evaluate recreation. The significant shortcomings of this method are widely understood and well documented in several studies (Ready and Navrud, 2005, Lindsey et al, 2004). Using an approach with such limitations only results in biased data. A contemporary model like hedonic pricing would serve better in estimating recreational impacts. For the Final EIS, the Corps needs to more adequately assess lower basin recreation with a more contemporary economic model.

Comment Text: Improvement of the recreational potential of the mainstem river. Recreation is an Authorized Use but the Corps limits recreation almost entirely to recreation on the reservoirs. The Corps does little, to nothing, to facilitate recreation on the river downstream of Gavins Point - using the not their responsibility/authorization as justification. This seems to be an absconding of due diligence of their responsibilities as caretakers of the management of the system. Opportunities for fishing, boating, nature seekers, and just about any recreational pursuit are impacted by 1) lack of accessibility to the river from the banks because of the conversion of the river into an unused navigation channel in the NE-IA reach; 2) a significantly dangerous velocity - as a past Director of IA DNR described the river a dangerous ditch! So while many other rivers in this country have recreational opportunities, the Missouri River has not nearly what it could have. The high speed of the current is not conducive to canoeing, kayaking, small motor fishing boats, rafting or swimming. With steep banks and no shallow water, there can be little fishing from the shore, no camping along the shore, nor picnics or shoreline lunches. Even hiking or equestrian trails dont exist. However there are numerous recreational vehicle established camp grounds all along the river. They are situated there because people are drawn to rivers, and this will increase as population increases. Sadly, the Corps did not consider these settlements in their Human Considerations for Recreation.

Comment Text: Recreation Technical Report Comments The unit day value (UDV) method was used to evaluate National Economic Development (NED) impacts of the alternatives on recreation in the Missouri River basin. This method relied on the opinions of the project managers for assigning points that ultimately determine the unit day value for each reservoir/reach. Additionally, under this method, boating is included in the general recreation category which has a lower range of unit day values than the general fishing category. This is not appropriate for the upper 5 reservoirs, since the majority of boaters are engaging in fishing activity. This highly subjective valuation method may be fine for simply comparing impacts of the different alternatives, but not for weighing impacts

between interest groups. We ask that the USAGE utilize the Regional Economic Development (RED) RECON valuation method that is based on expense/revenue data for estimation of economic impact when comparing benefit/loss across multiple interest categories.

Comment Text: Spring Flows to Create Emergent Sandbar Habitat (Alternative 4) If System storage is at 42 million acre feet (MAF) or greater on April 1, natural flows creating 250 acres of ESH have not occurred in the previous four years, and downstream flow limits are not exceeded, ESH creating flows would be implemented on April 1 with a release of up to 60, 000 cfs out of Gavins Point Dam, and as often as every 4 years. 1. Sandbar habitat-creating flows have the potential to severely impact the sport fishery of Lewis and Clark Lake. While other Missouri River reservoir fisheries generally respond positively to above average water yield, the small relative size of Lewis and Clark Lake results in a low storage ratio and detrimental impacts caused by high flushing rates. Walleye population abundance in Lewis and Clark Lake is negatively correlated to total water yield through Gavins Point Dam. The most likely cause for this correlation is the flushing of newly-hatched walleye from the lake through Gavins Point Dam during average to above average water yield years. Increased flows in April and May would likely have detrimental impacts to the sportfish population through increased flushing of newly hatched walleye through the dam. 2. A correlation exists between the average annual elevation of Lake Oahe and the amount of angler use and was used in some of the modeling for the Recreation Technical Report. However, major flow events result in degraded fishery quality and angler use a few years after their occurrence, resulting in low angler use even at high reservoir elevations. Major flow events have the ability to flush the majority of pelagic prey (rainbow smelt and lake herring) and Chinook salmon through Oahe Dam. Even if reservoir elevations are sufficient to allow good access to the reservoir after major flow events, the lack of available food resources results in the loss of the larger walleye from the reservoir due to starvation. This occurred after large flow events in 1997 and 2011 and it took Lake Oahe over 5 years to recover each time. The Chinook salmon population in Lake Oahe was severely reduced by the 1997 and 2011 flow events, and as with the walleye fishery, has taken over 5 years to recover from each event. Timing of flow events, with regards to stratification of the water column in Lake Oahe and fish distribution within the water column, is a primary consideration when predicting impacts of high flows on the Lake Oahe recreational fishery. 3. Decreasing elevation of Lake Oahe and Francis Case during prey and game fish spawning periods (April - June) is a concern as stable-to-rising elevations are important to the success of prey fish and sportfish spawning events and egg incubation. With Lake Oahe being the lowest of the big-three storage reservoirs in the system, a spring release to create ESH will certainly remove the possibility of favorable conditions for spawning during the year of the flow implementation. Lake Francis Case is a much smaller reservoir than Oahe and the lowest source of available water for adjustments to releases from Gavins Point Dam. The need for an immediate source of water to support flow-related management actions could affect the elevation of Lake Francis Case during

walleye spawning, thereby reducing the stability and quality of the walleye fishery, which contributes significantly to the recreation industry in South Dakota.

Comment Text: Table 2-31 (Summary of the Alternatives Impacts), by National Elevation Dataset suggested recreation would experience a positive impact from Alternative 2 compared to the No Action Alternative, while Regional Economic Data analysis estimates that Alternative 2 will have a negative impact on recreation compared to the No Action Alternative (Alternative 1). Water depth alone may not be an accurate predictor of habitat availability, recreational use, and subsequent recreational economic impact. Aquatic wildlife pursued by recreational users will occupy habitats when water depth, velocity, and temperature - along with other factors - are aligned for the target species. Water velocity can be both a physical and behavioral barrier to habitat occupancy, while temperature will affect fish activity. More detail on the assumptions and analysis of recreation impacts for the proposed Alternatives would be helpful.

Comment Text: The Missouri River System Fisheries Management Plan identifies specific water management recommendations that are critical for maintaining a sustainable and productive fishery (Fryda et al. 2010). Select recommendations presented below would be at best vastly compromised or more likely never met under a significant Lake Sakakawea drawdown. The NDGFD, under no circumstance, could support such a Level 2 or above action in the MRRMP-AMP. Fishery Recommendations for Lake Sakakawea: 1. An absolute open-water minimum lake elevation of 1825 ft. msl for drought periods and 1832 ft. msl for all other years is recommended. Below these specified elevations, the following detrimental impacts occur to the fishery resource or affect its use: dramatic declines in reservoir productivity, a substantial loss of walleye and smelt spawning substrate (gravel/cobble) and coldwater habitat (for rainbow smelt and Chinook salmon); critically needed water becomes less available to the Garrison Dam National Fish Hatchery for production; and boat access/recreation use becomes limited. 2. Other than years in which severe drought or flood conditions prevail, a maximum lake elevation window of 1838 to 1846 ft. msl is requested in order to maintain flexibility in annual recommendations and to reduce impacts from wave erosion. 3. The spring water level rise must inundate good spawning substrate

(i.e. cobble and/or terrestrial vegetation) by April 20 and continue to rise during spawning-incubation (April-May). A target increase of two to three feet between April 20 and May 20 should occur during a filling cycle. Even during a drawdown cycle or during drought conditions, a rising lake elevation should be attempted during this critical time period. Fryda, D. and S. Gangl. 2016. Angler Use and Sportfishing Catch Survey on Lake Sakakawea, May 1 Through September 30, 2015. ND Game and Fish Dept. f-2R-61, Study 4, Number 1. Fryda, D., F. Ryckman, R. Kinzler and P. Bailey. 2014. Comment Text: Data collected by NDGFD over the decades have shown conclusively that a rising pool level and the lake elevation are the two strongest environmental variables that correlate with annual production of all young of year fish (Fryda et al. 2014; Fryda et al. 2010,). Lake elevation is also critical for the maintenance of cold water fish habitat in Lake Sakakawea. Low lake elevations in past drought periods have caused reduction/elimination of cold water habitat, caused hypoxia in the hypolimnion, and devastated the chinook salmon and rainbow smelt populations. Additionally, the headwaters region of Lake Sakakawea that would be dewatered is a critical rearing area for juvenile paddlefish. The Yellowstone/Sakakawea stock of paddlefish is one of the most scientifically understood paddlefish populations in North America. Extensive research has shown good inflows combined with high lake levels are crucial for recruitment to this nationally important self-sustaining paddlefish population (Scarnecchia et al. 2008). Lake Sakakawea is typically the most heavily utilized fishery in North Dakota and annually accounts for over 30 percent of all fishing effort in the state. In 2015 alone, anglers expended over one million hours of angling effort on Lake Sakakawea (Fryda and Gangl 2016). Expenditures generated by these anglers are vitally important to the regional economy. Significant drawdown of Lake Sakakawea would have major impacts to these economies due to impacted fish populations and poor to non-existent access caused by low lake elevations.

Comment Text: North Dakota's Game and Fish Department (NDGFD) is fortunate to have long-term data for the various MRS fisheries within the state. Datasets for Sakakawea (60 years) and Oahe (49 years) have given fishery managers a very good understanding of what conditions are critical for sustaining healthy fish populations on these vitally important fisheries. Responsible water management has, and always will be, the most critical factor in maintaining these fisheries. The vast amounts of data collected over the last 60 years of sportfish management have pointed to two basic needs for our fisheries to flourish. First, reservoirs must maintain adequate water levels to provide quality habitat. Second, water levels must rise during the critical spring spawning and egg incubation period (Fryda et al. 2014, Fryda et al. 2010, Scarnecchia et al. 2008). Without these water conditions, the fisheries suffer greatly as they did during the drought of the early 2000s. Any alternatives in the MRRMP-EIS or actions identified in the AMP that increase the frequency of not meeting these basic water conditions are detrimental to the fishery, and are contrary to the management goals and responsibilities of NDGFD's Fisheries Management Division.

EC1700 Environmental Consequences: Thermal Power (Substantive)

Correspondence Id: 118 **Comment Id:** 633750 **Coder Name:** jgutierrez

Comment Text: Additionally, KCP&L wants to reinforce its concerns regarding Alternative 2 and other alternatives. Alternative 2 currently proposes low summer flows under certain conditions. In the Draft Science and Adaptive Management Plan it outlines a low summer flow of 21,000 cubic feet per second (CFS) from Gavin's Point. Efficiency of power plant operations at KCP&L is threatened at that level of flow due to the shallow depth of water at the cooling water intakes. The plants would not be able to run at peak efficiency and would have to derate. This flow could also impact power production due to river temperature restrictions in plant operating permits. Low summer flow would mean the temperature of the lower Missouri River would more easily reach 90 degrees, limiting KCP&L's ability to produce power during high electrical usage times. Both of these scenarios impacts KCP&L's ability to interact in the Southwest Power Pool market and could mean higher costs of energy for our customers as well as increased maintenance costs.

Comment Text: General Analysis: 1. Significant reductions in energy as a result of shutdowns of baseload thermal power plants caused by lower summer flow in Alternative 2 could lead to problems with system reliability. 2. The DEIS analyzes impacts from only a cost perspective, assuming offset energy is available. The Corps has not conducted the analysis needed to determine if this energy would be available from the market or if the transmission facilities could deliver the needed replacement energy. 3. The NED and RED analysis indicate significant financial impacts to thermal power generating facilities below Gavins Point from an energy and capacity perspective and are likely underestimated. 4. The DEIS analysis of impacts to thermal power does not seem to be representative of actions within the various management plan alternatives. This could be because of a small number of years analyzed from a temperature and operational perspective, inappropriate modeling assumptions or both.

Comment Text: The CPR is also very apprehensive of the impact that low summer flows would have on energy generation, water supply intakes and sewer treatment plants. We believe operational costs under a low summer flow regime are severely underestimated and should be reexamined. Further, we request the Corps to identify all potential regulatory burdens in advance of the implementation of any management plan action. In any instance in which the regulatory cost of compliance increases (i.e. modification of intakes), thorough input needs to be gathered from affected industry sectors to ensure that the impact to both utility companies and ratepayers alike remains minimal.

Comment Text: In Iowa, there are four coal fired power plants with a total capacity of approximately 2,800 megawatts located near the Missouri River. Some of these thermal generation units depend on the river for cooling water and ash handling. Without the needed stages and flows, these units do not have sufficient cooling capacity to operate, forcing the owners to generate power from more expensive units or purchase power at wholesale market rates. These plants provide year-round base load energy for Iowa industries, commercial businesses, and residential customers, and are critical to the economic well-being of the state of Iowa.

Comment Text: Although many of the comments above have a reliability component, Montana-Dakota provides some additional thought on concerns with reliability and the USACE's proposed alternatives. If Heskett Station was not able to run due to low water at our intake, this could impact Montana-Dakota's ability to accredit all the Heskett units' output capacity in MISO and possibly impact system reliability in the area. The loss of capacity accreditation at Heskett could require Montana-Dakota to construct a replacement unit (which may need water from the river also) or enter into a contract for replacement capacity or purchased power to make up the generation. Heskett Station generation is also positioned strategically to support Montana-Dakota's customer load in the Bismarck/Mandan area and a loss of Heskett generation could directly impact local system reliability and the need for additional transmission upgrades. Montana-Dakota would incur significant costs to replace the loss of generation and there may not even be an available replacement, or it may take multiple years to construct a new resource. Permitting new generation would take a significant amount of time, and but for the USACE low flows, that generation may not have been warranted. As described earlier, if Heskett was receiving flows that were low enough to create shutdown conditions, then other electric generation facilities upstream (and downstream of Garrison Dam) may also be at risk of a shutdown, resulting in no generation from multiple facilities at the same time. If this type of event would coincide with a period of high demand, the impact to the grid system could result in significant regional transmission impacts. Further study of the likelihood of this occurrence in consideration of the USACE's implementation of an alternative should be completed to ensure this scenario does not occur. These generating units along the Missouri River are modeled

to be available to run by the regional transmission organizations. Detailed studies are required to determine the impacts to the transmission system if these generating units along the Missouri River are not available to run during a portion of the year and the impacts on system reliability.

Comment Text: Montana-Dakota understands that daily average flows can be the culmination of large discharge swings (1.5 to 3 feet as noted in the report) within a 24 hour period caused by the hydroelectric generation fluctuating to follow electric loads. Due to the swings within a 24 hour period, Montana-Dakota believes it appropriate for the USACE to consider the hourly minimum flows and not an average across a day when evaluating impacts to downstream water users. These swings within a 24 hour period can be observed by river gauges. Montana-Dakota suggests the USACE review the hourly flows, or possibly watch how the river recedes after a load change is made, to determine how conservative they should be. As noted below, it appears this swing is taken into account when the USACE is considering bird nesting, but the agency should also consider the swing when determining impacts on other water uses and users to more accurately reflect increased facility shutdown occurrences.

Comment Text: Further support for keeping the minimum flows at least above 10,000 cfs (to avoid shutdown at Heskett Station) is in Section 2.3.1.5.3 Minimum Releases of the Mainstem Missouri River reservoir Simulation report that states: ". . . Minimum daily releases at Fort Peck, Garrison, Fort Randall, and Gavins Point are established as those necessary to supply water quality control and downstream water intake requirements, which generally also furnish more than an adequate quantity of water for irrigation withdrawals below the reservoirs. At Garrison a minimum average daily release of 9,000 cfs has been established as a guide to provide for downstream intakes. Access problems have been experienced at municipal, industrial, powerplant, and irrigation intakes along the length of the river due to channel degradation, inadequate intake screens, sandbar formation, winter ice formation, or relatively high elevation of the intakes. Temporary increases above the open- water minimum release rates may be made to the extent reasonably possible to allow intake owners to take remedial action." These USACE statements show the history of established flow levels considered for operation impacts and support that the EIS model predicted impacts have a relatively high degree of uncertainty.

Montana-Dakota recommends the USACE apply a more conservative approach when incorporating minimum daily releases and impacts at intakes. Additional discussion is provided in the following comment.

Comment Text: Disagreement with Use of 2012 Geometry and Model Predictive Accuracy Based on Heskett Observations

Montana-Dakota would like to emphasize that we do not agree with the use of the Management Plan and EIS using the 2012 channel geometry model to evaluate the impacts of the alternatives if the model has not been proven to be accurate at low flows (those under 15,000 cfs) at Heskett's intake since it appears the only model comparison was done with 2012 observations. The concern extends to USACE's assumptions of the impacts projected from low releases using this modeling. It appears that the USACE model associated with this project uses historical flows and the 2012 river geometry survey to predict the impact to the Heskett intake and whether the station would be able to withdraw from the river (based on the intake elevations and modeled results). It appears that the model does not take into account channel changes since the survey was conducted, as well as Oahe Lake effects within the river reach near Heskett and channel siltation. In our experience, the channel changes yearly as winter ice freezes over the river and re-directs flows differently each year underneath the ice until ice breakup occurs. We are also concerned that actual elevations at Heskett's intake were not confirmed at the time of the 2012 survey. Due to the changes that occur yearly in the stretch between Bismarck and Garrison Dam, we feel the 2012 survey is not accurately representing the flow impacts near Heskett. Montana-Dakota requests that the USACE confirm whether the model corresponds to flow and elevations outside of the 2012 survey timeframe and make model adjustments accordingly to demonstrate accurate predictions. Additionally, we recommend the USACE consider evaluating this for all affected water users. Montana-Dakota recommends the USACE also review the model accuracy to consider the consequences of multiple stations along the Missouri River being affected by low releases. The effect of the loss of generation from multiple facilities in a single period is much more significant than the loss of generation from one facility. Loss of generation from multiple regional or local generation resources may have the potential for a larger impact to transmission grid reliability. This subject requires more than the limited amount of discussion found on page 3-475 of the MRRMP-EIS. Further, Montana-Dakota believes that a reliability impact from implementing the alternatives is beyond what is considered as a loss of revenue if multiple generation resources would be offline, and we recommend USACE include reliability consideration in the impact analysis of the alternatives.

Comment Text: Montana-Dakota does not agree with the USACE's assumption that renewable electric generation resources would be able to replace the lost capacity of thermal fossil-fired electric generation resource if an Alternative results in curtailment or shutdown of the resource. Under each of the alternatives, the USACE uses a similar argument that renewable generation offsets the generation from shutdown or curtailment of fossil-fired electric generation. This is not quite accurate. The electric load balancing services from dispatchable fossil-fired electric generating units provide a reliable, low-cost and stable transmission grid that intermittent renewable electric generation resources are not able to provide. Renewable electric generation resources such as hydropower and wind-powered generation resources should not be represented as equals when considering offsets and costs since these resources must be backed up by dispatchable electric generation resources. The USACE's support must also consider transmission grid upgrades when representing the "Other Social Effects" associated with the alternatives. More value should be applied to dispatchable electric generation resources where the USACE considers benefits from emissions reductions and uses the social cost of carbon when crafting financial statements in the draft. Also, please consider that the president has required Review of Estimates of the Social Cost of Carbon in Executive Order "Promoting Energy Independence and Economic Growth" released on March 28, 2017 and is expected to change.

Comment Text: Montana-Dakota's main concerns are that Heskett would encounter significant operational impacts, including limitations in providing fire protection safety for the facility, and shutdowns if there was not sufficient river flow provided by the Alternatives and could not obtain water for station needs at the station's river intake. There is a possibility for more severe impacts resulting from implementation of USACE proposed Alternatives 2, 4 and 5 due to lower river flows anticipated near Heskett with these alternatives. Although there is also a potential that Alternative 3 could result in some operational impacts, it is projected to be less than the other proposals. Montana-Dakota views Alternative 3 as the least disruptive alternative considering lower projected impacts for Heskett. Montana-Dakota has concerns with the USACE assumptions under all alternatives and recommends the USACE conduct further evaluation according to our comment details.

Comment Text: NPPD is concerned with the analysis of impacts to thermal power contained in the DEIS. The NED and RED analysis indicate significant financial impacts to thermal power generating facilities below Gavins Point Dam from an energy and capacity perspective. We also believe they are likely underestimated. Additionally, the results presented in the DEIS do not seem to be representative of the operational variations of the management actions described for the alternatives. This may be due to the limited years analyzed from a temperature and operational perspective, inappropriate modelling assumptions or both. We would recommend that in the Final Environmental Impact Statement the USACOE provide the impacts based on the type of impacts for the specific thermal power facilities.

Organization: Nebraska Public Power District

Comment Text: While the DEIS provides scant discussion on the impacts to reliability from either the reduced hydroelectric or thermal generation output, there seems to have been no consideration of the cumulative impacts to the reliability of the power grid from the loss of both hydroelectric and thermal generation under the various alternatives. As the DEIS analyses show, lower or altered Missouri River flows can significantly reduce the output or value of hydroelectric generation and at the same time reduce the amount of thermal generation available. What was apparently not considered was the cumulative impact of the loss of both types of generation and the consequent impact on system reliability. The loss of significant amounts of baseload generation at the same time can seriously impact system reliability. It is not clear that sufficient transmission capacity exists to be able to purchase and import power from the market to replace the lost generation or that the market is liquid enough to absorb the necessary replacement power purchases without significant price increases. It is imperative that the cumulative impact of changes in hydroelectric and thermal generation output on power system reliability be addressed in the final environmental impact statement to assess to what degree grid stability may be at risk under the various alternatives.

Comment Text: In addition to the costs of decreased generation capacity due to low summer flows, the report also assumed there would be a small increase in maintenance costs for cleaning debris and sediment from Missouri River intakes due to increased

aggradation from proposed seasonal flow pulses in Alternatives 1, 2, 4, 5, and 6. This assumption does not recognize the limitations of maintenance activities set forth in the Special Conditions of the Department of the Army Nationwide Permit No. 3b found in the February 21, 2012 Federal Register (77 FR 10184). These Special Conditions for MidAmerican facilities include the restriction that no work shall occur below the ordinary high watermark from March 1 to June 30 to avoid impacts to Pallid Sturgeon (USACE Permit No: 2013-00165-WEH). MidAmerican schedules intake structure maintenance outside this protective period to ensure that sediment aggradation during the protective period does not require a derate or complete shutdown of the intake structure and operating unit. The assumptions concerning increased aggradation from proposed seasonal flow pulses should be revised to account for potential derate or shutdown impacts should significant aggradation occur during the pallid sturgeon protective period identified in the special conditions to nationwide permit 3.

Comment Text: Section & Page Number: 3.19.2.1, p. 3-528 "The scope of analysis included facilities in Iowa, Nebraska, Kansas, and Missouri. Facilities in North Dakota and South Dakota were eliminated from further analysis because state water quality regulators indicated that low-flow conditions in the Missouri River do not drive effluent limits for facilities in these states." **Comment:** Current low-flow conditions in the Missouri River will not impede the ability for permitted facilities to discharge to the river. However, reductions to the flow regime due to adaptive management or the building of new facilities may affect the ability to discharge wastewater to the Missouri River in the future.

Comment Text: Section 3.19 Wastewater Facilities General Analysis: 1. We are concerned with the DEIS findings that five wastewater treatment plants (two in Iowa, three in Missouri) could be affected by low flow conditions specified in Alternative 2. Section 3.19.2.5 states: Impacts of the habitat construction management actions on wastewater facility outfalls could range from negligible to large, long-term and adverse on wastewater facilities compared to Alternative 1, depending on the proximity of the constructed habitat site to wastewater facilities 2. The DEIS wrongly assumes that wastewater authorities will be able to make improvements as needed to account for management changes such as low flow. This assumption cannot be reliably made because it depends on too many variables, such as funding, changing requirements, local logistics and permitting.

Comment Text: The CPR is also very apprehensive of the impact that low summer flows would have on energy generation, water supply intakes and sewer treatment plants. We believe operational costs under a low summer flow regime are severely underestimated and should be reexamined. Further, we request the Corps to identify all potential regulatory burdens in advance of the implementation of any management plan action. In any instance in which the regulatory cost of compliance increases (i.e. modification of intakes), thorough input needs to be gathered from affected industry sectors to ensure that the impact to both utility companies and ratepayers alike remains minimal.

Comment Text: KCMO operates six (6) wastewater treatment plants under National Pollution Discharge Elimination System NPDES permits, three (3) of which discharge to the Missouri River under NPDES permits. These permits are based in part on flows denoted 7Q10 and 3DQ10. Each one has different limits based on the flows and other factors. In the DEIS the COE surveyed the

states, EPA and the affected plants as to their permit basis and method of calculation (i.e. Q, low flow, carcinogenic, and acute v chronic). They concluded impacts were low to none under all alternatives with the caveat that under alternative 2, three (3) plants in Missouri could be affected by low flow. They concluded through dialog with plant personnel, that planned upgrades would negate negative impacts on the treatment plant. But if those improvements were not made, treatment plant NPDES discharge standards would most likely be impacted under Alternative 2. Although not directly identified in the DEIS, staff does believe that the Blue River WWTP would be negatively impacted by the above alternative. The DEIS states that Alternative 3 would have negligible impacts.

Comment Text: The Corps alludes to the impacts on the Tribes on page 3-545 of the Draft EIS, as part of "other social impacts" of the no action alternative. The Corps states "Alternative 1 is not anticipated to have significant impacts on subsistence hunting, fishing and gathering, or traditional Tribal practices and educational opportunities." This alternative reflects the status quo, in which the Corps of Engineers operates the dams pursuant to the current Master Manual, with limited mechanical habitat restoration projects and periodic spring rise. As stated above, the operation of the dams have a significant adverse effect on the Tribes. Consequently, Alternative 1, which is no action, adversely affects the Tribes. The findings on page 3-545 of the Draft EIS are invalid.

Comment Text: The Draft EIS includes an "Other social effects" analysis, and the Corps argues that this includes an evaluation of impacts on Tribal subsistence activities. (Draft EIS, chapter 3 .20). However, the document contains no baseline data on important Tribal species. The Corps merely theorizes about the extent of woody habitat under various alternatives, and makes unsubstantiated generalizations about the abundance of important Tribal species. "While a variety of physical conditions are required for recruitment and establishment of cottonwoods, the presence of habitat could be beneficial to the abundance of species important for traditional cultural practices, including cottonwoods." (Draft EIS, p. 3-545). That does not support a finding of no impacts. It certainly does not constitute an "analysis of identifiable impacts" as required by CEQ.

Comment Text: Alternative 5 - The League has concerns with Alternative 5. This alternative is contrary to the natural historic hydrograph of the river. Alternative 5 would have large flow releases in the fall instead of the spring, as in the natural hydrograph. We believe any habitat created through fall releases would suffer serious losses to wind and ice erosion over the winter. This would create short lived habitat that would be largely unused while least terns and piping plovers are on their wintering grounds far south of the Missouri River. We also have concerns with this alternative's potential impacts on pallid sturgeon and other native fish species, with such a large release at an unnatural time of year for the Missouri River.

Correspondence Id: 239 **Comment Id:** 645400 **Coder Name:** jgutierrez

Comment Text: Section & Page Number: 3.4.2.8, p. 3-102 "Tern and plover population dynamics following high flows in 1997 and 2011 indicate that sufficiently high flows produce population increases in subsequent years. The spring emergent sandbar habitat-creating reservoir release modeled as part of Alternative 4 would have longterm, relatively large beneficial impacts from the creation of new sandbars that could occur following flows." Comment: First, this statement contradicts the conclusion of Section 3.2.2.4, which said that Alternative 4 would not have significant impacts on geomorphology. The statement says that the release would have long-term, relatively large beneficial impacts from the creation of new sandbars. Second, the long-term benefit of the ESH-creating release would only last until the sediment supply was exhausted, or for the inter-dam reaches, until all of the sediment was flushed into the reservoir deltas. Third, the ESH-creating release would have an adverse effect by increasing the flood risk of birds nesting on sandbars. When discussing the effect of the spawning cue releases for Alternative 2 (Section 3.4.2.6, page 3-101) and Alternative 6 (Section 3.4.10, page 3-104), this risk of flooding nesting birds is recognized. It should also be recognized for Alternative 4. These comments also apply to the fall ESH-creating release (Alternative 5), which is discussed in Section 3.4.2.9 (page 3-103), with the exception of the comment on flooding nesting birds. The fall release as described would occur after nesting season.

Comment Text: Section 3.4.2.5, Page 3-100 - No significant, adverse impacts are anticipated under Alternative 1; however, it appears Alternative 1 would not meet the 95% chance of persistence over 50 years. Since the last dam on the Missouri system reached full capacity in 1967 (see page 3-14), which happens to be 57 years, and the plovers have maintained a population for the entire period should cause a re-evaluation of the modelling done for the DEIS to that determined that Alternative 1 (i.e. current management plus 107 acres of ESH created habitat) does not have a 95% chance of population persistence for the next 50 years. Again the plain facts do not support the modelling results. Since the first constructed island was completed in 2004 and the flood of 2011 washed out all constructed islands it is difficult for a reader to follow just how the construction of ESH would have changed the number of birds today or why it is necessary into the future.

Comment Text: Section 1.5.2, Page 1-24, Sub-Objective 2 - Concerning a 95% modeled probability that at least 50 birds will persist for 50 years (Northern and Southern Regions). Piping plover populations continue to exist on the river with fairly stable or increasing numbers (see 2015 Annual Report) despite the construction of dams on the Missouri River in the 1950s and little or no nesting in on the Missouri River or associated reservoirs in years like 1997 and 2011. Therefore modeling the Missouri as two separate populations that have little or no interaction and holding emigration and immigration as steady and equal in the models obviously does not take into account the reality of the bigger metapopulation influence and has some limitations. How those limitations affect the persistence

probability needs to be explained. Likewise if acres of ESH are to be used as a surrogate there should be a simple graph or table that demonstrates the historical relationship of plover populations to acres of ESH in the past to justify the proposed methodology.

Comment Text: In the case of the Piping Plover, since channelization, instances of breeding on the Missouri River itself, other than in the Gavins Point reach, have been rare to non-existent. Following major flood events such as 1997 and 2011, plovers have utilized naturally-formed ESH, but only for relatively short periods until such habitats became unsuitable, usually because of natural inundation from varying river levels, reduction in fledging success due to overcrowding, natural re-vegetation, and/or increasing access to predators (Anteau 2017). Attempts to create artificial ESH have had mixed success and have not contributed in any significant way even to the limited population of Piping Plovers using the Gavins Point site; there was no change in number of fledged Piping Plovers there from summer 2000 through summer 2009 (Figure 3, Duberstein 2011).

Correspondence Id: 179 **Comment Id:** 645232 **Coder Name:** jgutierrez

Comment Text: Throughout this entire DEIS process, through the many MRRIC meetings and discussions, Ecosystem Services were barely touched upon. It should have received a much greater analysis and prominence. Such things as in agriculture - when farmers complain if a willing seller sells the neighboring piece of ground to the Corps; county assessors and the farmers complain that acres were taken out of production and the county loses property taxes - these things are always pointed out. However, nothing is said about the reduction in flood risk by the new acres devoted to Recovery, or the savings in flood insurance or FEMA costs. Personally, I can add other factors which contribute to Ecosystem Services by these new acres out of production: infiltration of rain, greater diversity of plant species, increase in invertebrate diversity, prairie bird nesting, hunting opportunities, buffer crop or buildings from river rises, water quality enhancement, etc. The Corps needs to elaborate on quality of life in ecosystem services. Habitat producing land near metropolitan areas contributes to relaxation, stress reduction, and thus contributes to the health of a population. It provides interaction with nature which has deep roots in the human psyche. Such lands provide fellowship with others while hiking, boating, camping, fishing, and hunting clubs. Some individuals may feel a religious interaction with nature and their Creator. And not to mention the cultural and religious connections to the river by the Tribes, again, something not especially emphasized throughout these proceedings. It is asked that the Corps rewrite this section and do it in an acceptable manner. And although it states in the Executive Summary, pg.xxiii, that ecosystem services are discussed in other sections, I question the validity of that statement.

Comment Text: Of greater importance is: 1) Ecosystem services is rated the same for all alternatives! 2) there are different units used in the chart - again confusing for the public. It is suggested that perhaps the chart can be broken down into smaller sections; darker hash marks vs. lighter dots/lines be used rather than colors; and lastly, how in heavens name can ecosystem services be virtually unaffected???

Organization: Nebraska Wildlife Federation

Commenter: Marian Maas **Page:** **Paragraph:**

Kept Private: No

Correspondence Id: 240 **Comment Id:** 644960 **Coder Name:** jgutierrez

Comment Text: The MRRMP-EIS also does not make clear what is or is not included within the category of ecosystem services. The Executive Summary states that "notable ecosystem services" include: "natural resource goods ... water supply, water quality, waste assimilation and nutrient regulation ... , flood attenuation, recreation, and other cultural services." 134 However, most of those services also constitute their own categories which themselves are quantified. Impacts to cultural resources and recreation, for example, have significant quantitative variation among the alternatives, and that variation is also reflected in the color scheme in the chart of the Executive Summary.135 Since the full range of ecosystem benefits are not summarized within their own impact category, this separation obfuscates the MRRMP-EIS's analysis of ecosystem services. The Corps attempts to correct this confusion by limiting the category of ecosystem services to "climate regulation and carbon sequestration, other cultural resources, and non-use values,"136 yet nowhere quantifies those impacts for comparison of the alternatives. The closest the MRRMPEIS comes to giving meaning to

ecosystem services is Table 3-261 which lists "Environmental Consequences for Ecosystem Services," but even there, the alternatives are vaguely and qualitatively compared. 137 The Corps should correct these inconsistencies by giving values to ecosystem services as its own category and presenting them to the public in a quantified and comparative form. From this, the MRRMP-EIS can draw meaningful comparisons among the alternatives as to how they promote self-sustaining environmental services for the benefit of the public.

Comment Text: 9. Regarding navigation, the Corps needs to better study the linkage between the Missouri and Mississippi Rivers in terms of flow support and flooding impacts. The Missouri River can greatly affect the middle Mississippi and its contributions, positive or negative, should be clearly delineated in the DEIS.

Organization: Coalition to Protect the Missouri River

Commenter: Dan Engemann **Page:** **Paragraph:**

Kept Private: No

Correspondence Id: 228 **Comment Id:** 645623 **Coder Name:** jgutierrez

Comment Text: While the DEIS claims that these impacts on the middle Mississippi River will be small to negligible, the Corps own data concludes that the lower summer flows in Alternative 2 would result in a lower stage of approximately two feet in July and August . Such reduction in stage on the middle Mississippi in the busy summer months is not a small to negligible impact, especially during times of drought. A two-foot reduction would have severe consequences for shippers and consumers. The DEIS further concludes that the massive spring and fall releases in Alternatives 2, 4, 5, and 6 would increase the stage and flow on the middle Mississippi by one to three feet. Once again, these increases are not small or negligible, especially when they occur during peak flood season. Even the minimum low flow of 25,000 cfs for several weeks would have significant effects on navigation on the Mississippi River below St. Louis. These impacts would come in the form of reduced draft and tow sizes. Should the navigation industry have to reduce draft out of St. Louis to the Gulf because of insufficient flows, the cost to the nation would be, at a minimum, in the millions. In periods of high water on the Mississippi River, increasing the amount of water flowing in from the Missouri River and raising the stage by two to three feet would have serious impacts to the shippers, farmers, consumers, and communities along the river.

Organization: Coalition to Protect the Missouri River

Commenter: Dan Engemann **Page:** **Paragraph:**

Comment Text: The DEIS subsection Impact from Management Actions Common to All Alternatives states: It is anticipated that there will be no impacts to biological resources in the middle Mississippi River from the management actions common to all alternatives. The listed activities would occur on the Missouri river and would not impact the stage or flow on the middle Mississippi River. We cannot understand how the DEIS can draw this conclusion when it states in two different subsections of Section 3.24 - Mississippi River Impacts that the Missouri River contributes almost half of the flow to the middle Mississippi river. These conclusions in the DEIS are illogical. Section 3.24 further states that the impacts of Alternatives 2, 4, 5 and 6 on stage and flow in the middle Mississippi River would be small or negligible. This section also concludes that the impacts to flood risk management in the middle Mississippi River are not anticipated to be significant under Alternatives 3 through 6. Finally, this section claims that the impacts to navigation in the middle Mississippi River would not be significant under Alternatives 2 through 6. We strongly disagree with these conclusions in Section 3.24. We believe that the impacts to stage, flood control and navigation on the middle Mississippi River are significantly understated due to the flaws in the hydrological and economic models.

Organization: Coalition to Protect the Missouri River

Commenter: Dan Engemann **Page:** **Paragraph:**

Comment Text: The methodology used for the analysis of the impacts on the hydrology in the middle Mississippi River from the alternatives is similar to the methodology used for analyzing the impacts for the Missouri River. Regarding the methodology used for the analysis of Mississippi River impacts, the DEIS states the following: Specifically, the analysis of the flow alterations under the six alternatives was largely based on the HEC-ResSim and the HEC-RAS Modeling for the 82-year period of record. The DEIS concludes that, despite the massive spring and fall releases from the Gavins Point Dam in Alternatives 2, 4, 5, and 6, there would be no significant impacts to middle Mississippi river navigation from any of these alternatives. The DEIS also concludes that there would be no significant impact to middle Mississippi river navigation from the significantly lower summer flows contained in Alternative 2. These conclusions are hard to justify given the fact that the DEIS also states that the Missouri River contributes almost half the flow in the middle Mississippi River. The DEIS also claims that the spring and fall flow releases in Alternatives 2, 4, 5, and 6 would be partially to largely attenuated by the time they reach Hermann, Missouri, but does not provide any detailed analysis as to why this would be the case. Does the Corps just expect the large amount of extra water released from Gavins Point to stay in the Missouri River and not flow downstream into the Mississippi River?

Comment Text: In terms of the impacts of the alternatives on Mississippi River navigation, the DEIS evaluation does not use any of the four accounts: Environmental Quality Methodology (EC), NED, RED, or OSE. Instead, the Corps measures the impacts of the alternatives on Mississippi River navigation by analyzing commodity movement data from the Waterborne Commerce Statistics Center daily stage level data for the St. Louis gauge from the HEC-RAS Model for the entire period-of-record for each alternative. Therefore, the Corps has been using the four accounts (EC, NED, RED, OSE) throughout the DEIS, and then utilizes a completely different methodology to measure the alternatives impacts on Mississippi River navigation. Once again, the DEIS fails to explain the reason for this abrupt change in methods. The failure to perform a comprehensive RED analysis to measure the alternatives impacts on Mississippi River navigation is inexcusable and unacceptable. A comprehensive RED analysis for navigation would illustrate the negative impacts of the alternatives on the local and regional economic conditions (jobs, income, revenues). Finally, the failure to perform a comprehensive NED analysis on the impacts to the Mississippi River is also inexcusable and unacceptable given the Mississippi River's major contribution to the nation's economy. By failing to conduct a NED, RED, OSE, and EQ analysis in its modeling, the DEIS is significantly understating the economic, environmental, and social impacts of the alternatives on Mississippi River navigation.

Comment Text: 3.24 Mississippi River Impacts General Analysis: 1. Due to the critical impacts that Missouri River flows have on the Mississippi River, any future flow change could negatively impact commerce and the nations economy. 2. Pallid sturgeon are using the middle Mississippi and DEIS alternatives should consider the middle Mississippi and the Missouri Rivers as one and be evaluated as such. 3. We are concerned that the geographic scope of the DEIS does not include the middle Mississippi River from St. Louis, MO to Cairo, IL. The failure to include the middle Mississippi River in DEIS geographic scope raises questions about the Corps ability to accurately analyze the impacts of the alternatives on the Mississippi River. 4. The economic modeling and analysis of the DEIS alternatives on Mississippi River flood risk management and navigation is flawed and missing key data. 5. We believe the hydrological impacts of the proposed alternatives on Mississippi River navigation and stage levels are significantly understated.

Comment Text: In the DRAFT EIS, Mississippi River navigation impacts are completely ignored. Instead, the Corps rudimentarily examined "Riverine Infrastructure and Hydrologic Processes" and changes in river stage only during certain years. The Corps concluded impacts to stage would be small or negligible. We believe this an egregious oversight given the importance of inland waterways to the nation and we request the Corps correct it in the Final EIS. Please note the Upper Mississippi River corridor generates more than \$345 billion annually supporting over 1 million jobs (Economic Profile, Upper Mississippi River) and that increasing the number and level of navigation restrictions can have extremely significant economic consequences.

Comment Text: Many of the Corps' alternatives proposed in the DRAFT EIS would adversely impact and reduce flow support to the Mississippi River. These impacts largely result from the significant volumes of water expended early in the year causing Missouri River flow support reductions in the fall. Due to annual runoff patterns, fall and winter is also frequently a period of lower river stages on the middle Mississippi River. Our analysis indicates that Alternatives 2, 4, and 6 increase the number of days at low-water action levels during October, November, and December. Under these alternatives, the number of days of normal loading is reduced in these months and navigation restrictions shift to lower (i.e., more restrictive) action level categories with greater impacts. These impacts are substantial enough to not be muted even when evaluating annual impacts.

Comment Text: The proposed operational changes contained in the alternatives for the Missouri River also have impacts to flood risk management on the Mississippi River. The Missouri River contributes, on average, 40 percent of the flow to the Mississippi River at St. Louis. As recently as 2015, significant high water events have occurred on the Mississippi River when new records for both Cape Girardeau and Thebes gages were established. Increasing flow from Gavins Point Dam while the Mississippi River is experiencing flooding could present a significant threat to public safety. Once water is released from the Gavins Point Dam, it travels over 800 miles down the Missouri River before it reaches the Mississippi River. This process typically takes approximately ten days and the water cannot be recalled once released. This creates a serious potential for the environmental flow releases on the Missouri River to coincide with regional flooding on the middle Mississippi River and increase flood risk for communities along the middle Mississippi River.

Comment Text: Section 3.24 further states that the impacts of Alternatives 2, 4, 5 and 6 on stage and flow in the middle Mississippi River would be small or negligible. This section also concludes that the impacts to flood risk management in the middle Mississippi River are not anticipated to be significant under Alternatives 3 through 6. Finally, this section claims that the impacts to navigation in

the middle Mississippi River would not be significant under Alternatives 2 through 6. AWO strongly disagrees with these conclusions in Section 3.24. We believe that the impacts to stage, flood control and navigation on the middle Mississippi River are significantly understated due to the flaws in the hydrological and economic models. However, while the DEIS claims that these impacts on the middle Mississippi River will be small to negligible, the Corps data concludes that the lower summer flows in Alternative 2 would result in a lower stage of approximately two feet in July and August. This two-foot reduction in stage on the middle Mississippi in the busy summer months is not a small to negligible impact, especially during times of drought. This two-foot reduction would have severe impacts on shipping costs. The DEIS further concludes that the massive spring and fall releases in Alternatives 2, 4, 5, and 6 would increase the stage and flow on the middle Mississippi by one to three feet. Once again, these increases are not small or negligible, especially when they occur during peak flood season. Even the minimum low flow of 25,000 cfs for several weeks would have significant effects on navigation on the Mississippi River. These impacts would come in the form of reduced draft and tow sizes. Reduced draft or tow size out of St. Louis to the Gulf because of insufficient flows would cost to the nation, at a minimum, millions. In periods of high water on the Mississippi River, increasing the amount of water flowing in from the Missouri River and raising the stage by two to three feet would have grave impacts to the shippers, farmers, consumers, and communities along the river.

Comment Text: Does the Corps just expect the large amount of extra water released from Gavins Point to stay in the Missouri River and not flow downstream into the Mississippi River? This question seems to be answered later under the Subsection Impact from Management Actions Common to All Alternatives where it states the following: It is anticipated that there will be no impacts to biological resources in the middle Mississippi River from the management actions common to all alternatives. The listed activities would occur on the Missouri River and would not impact the stage or flow on the middle Mississippi River. Once again, it is hard to understand how the DEIS can draw this conclusion when it states in two different subsections of Section 3.24-Mississippi River Impacts that the Missouri River contributes almost half of the flow to the middle Mississippi River. The conclusions are illogical.

Comment Text: Dr. Bray and Dr. Burton concluded that there is not enough waterway traffic on the on the Missouri River to capture, and therefore, measurable water-compelled railroad rates attributable to the Missouri River commercial navigation seems improbable. This conclusion ignores the fundamental principle of water-compelled rates and does not account for the recent increase and continued growth of navigation on the Missouri River. The failure to include an independent comprehensive analysis of water compelled-rates in the DEIS is inappropriate and unacceptable. By not including this analysis, the Corps has drastically understated both the economic benefits of navigation and the impacts of these alternatives on both Missouri and Mississippi River navigation.

Comment Text: The DEIS indicates that the impacts to flood risk management in Section 3.24 were evaluated using two of the four economic account models: NED and OSE. By only using these two accounts to evaluate the impacts to flood risk management, the DEIS has omitted key data points resulting in a major understatement of the costs and impacts to Mississippi River flood control interests. The failure to perform a comprehensive RED analysis to measure the impacts to flood risk management on the Mississippi River is very concerning. In addition to this, the DEIS does not indicate the reason an RED impact analysis was not performed. A comprehensive RED analysis for the Mississippi River, if done properly, would illustrate the negative impacts of these alternatives on local and regional economic conditions, such as employment, income, sales, sales tax revenue, flood damages, and other potential costs.

Comment Text: The purpose of today's written testimony is to express opposition to the proposed changes/alternatives to the management of the Missouri River Basin. The implementation of the proposed changes/alternatives, based on the draft environmental impact statement, cause a significant impact to the Middle Mississippi River system located north of Cairo, IL for both flood control and navigation. The potential effect to the water surface elevation of the Mississippi River near Cape Girardeau Missouri, with the proposed changes/alternatives, produce a river stage increase in excess of 3 ft. Any change/alternative producing an induced increase to the water surface elevation on the middle and lower Mississippi River is unacceptable. Not only will the proposed alternatives potentially negatively impact the people and property protected by the MR&T system, but it will also affect those who farm in and along flood ways of the Mississippi River Watershed. In LRDD's District alone approximately 6,500 acres of farmland in the area known as the "East Basin" would be impacted by water surface elevation increases.

Comment Text: "One of the major deficiencies in the economic modeling in the DEIS is it relies too heavily on averages, despite the availability of more detailed information previously documented. The economic impacts of the proposed Alternatives on human considerations in the DEIS are measured over an 82-year period-of-record. This timeframe and hydrological period-of-record cannot properly represent the true impacts of the proposed Alternatives on various stakeholders, as it skews the effects of major high water and low water events, such as the great floods of 1993 and 2011, as well as the severe droughts of 1988, 1989 and 2012. Under this 82-year period-of-record, the negative impacts of these Alternatives are significantly understated in the DEIS. This is particularly the case regarding the severe negative impacts to the resiliency of the navigation industry from the drought of the late 1980s.

Comment Text: In the Draft EIS, the Corps mistakenly assumes that the environmental impacts of all alternatives will be equal in light of climate change. It states on page 3-227 - Extremes in climate will likely also magnify periods of wet or dry weather, resulting in longer, more severe droughts, and larger more extensive flooding. Likely impacts to cultural resources would follow from increases to variability of reservoir water surface elevations ... However, it is assumed that the conclusions described would be similar under each alternative. The degree of water elevation fluctuation determines the magnitude of impact to cultural resources at the main stem reservoirs. Each alternative will cause different levels of fluctuation. As acknowledged by the Corps, climate change will intensify both catastrophic rain events and droughts. Consequently, the water level fluctuations will increase exponentially, not arithmetically. The assumption that the impacts of climate change are equal under all alternatives is erroneous.

Comment Text: Finally, because climate damages are uncertain and likely will not be distributed equally across the country, the Corps should use an increased SCC. The SCC figure used in the USACE analysis here does not reflect current understandings of the degree to which climate damages are uncertain and uses base-case projections that mask the impact of a number of potentially catastrophic outcomes. Given people's general aversion to extreme losses, future Corps' management studies and environmental impact statements should increase the SCC to reflect the uncertainty of climate impacts and the potential for catastrophic damage scenarios. No matter what possible climate change damages ultimately come to pass, costs associated with climate change impacts will likely be unevenly distributed. Current calculations model the SCC by aggregating and averaging damages. In reality, however, it is likely that the damages of climate change will be experienced in different modes and to very different degrees by different populations in different regions; for example, damages will likely be far greater in coastal areas subject to sea level rise and flooding, like Miami, than inland areas with very cold winters like Minneapolis. Because there is declining marginal utility to consumption, when a few individuals suffer significant damages and others experience smaller costs, the overall cost to social welfare is greater than if all individuals suffered an averaged level of harm. As a result, in future analyses, the Corps should adopt a higher social cost of carbon to account for the concentrated harms of climate change.

Correspondence Id: 171 **Comment Id:** 645197 **Coder Name:** jgutierrez

Comment Text: The USACE should continue to monetize the social costs of carbon by accounting for the global harms caused by climate change. Including global effects of climate change in the SCC makes it more likely that other countries will accurately account for climate change risks in their own decision making and strengthens the United States ability to persuade other countries to reduce their own GHG emissions. Because climate change is fundamentally a global phenomenon, reductions of GHG emissions in other countries will benefit U.S. citizens. Specifically, the United States will benefit if China, India, the European Union, and other major emitters reduce their emissions. Using a global SCC will increase the probability that other countries will take decisive action to reduce their own GHG emissions. Therefore, using global damages in calculating the SCC will have the important benefit of increasing the likelihood of greater emissions reductions abroad. The Paris Climate Agreement, in which nearly 200 countries agreed to take action on carbon emissions, demonstrates this benefit. This effect is perhaps even more evident in the bilateral announcement of U.S. and Chinese commitments with respect to GHG emissions reductions, which was announced in advance of the Paris Climate Agreement and involved U.S. leadership producing the first Chinese commitment to halt and ultimately reverse growth in its GHG

emissions. We have already witnessed how U.S. commitments to account for and address climate impacts can produce international reductions in projected GHG emissions. Just like domestic GHG emissions reductions, those international reductions will produce real domestic benefits in terms of mitigating climate damages that will be experienced by U.S. citizens and residents on U.S. soil.

Comment Text: In future management plans and impact analyses, the USACE should also use higher underlying estimates for the damages from climate change. When the USACE estimated the SCC for this management plan, it relied on the best data available to it at the time. But the models the USACE relied on were based on studies that are approximately two decades old, and more accurate information is now available. In fact, since 2009, scientists have released roughly 150 reputable studies that indicate that climate change will cause even more significant damages than initially anticipated. Indeed, evidence of faster-than expected retreat of the West Antarctic ice sheet, newer findings related to human health, and concerns about heat, food prices, and violence all point toward increasing estimates of future climate change damages. The USACE did not incorporate this improved and available scientific, technical and economic information into its current calculation; moving forward, it should.

Correspondence Id: 171 **Comment Id:** 645195 **Coder Name:** jgutierrez

Comment Text: Because climate change poses substantial and substantially uncertain risks, agencies should use a lower discount rate to hedge against potentially significant future damages. A low discount rate is appropriate in light of the possibilities that continued carbon emissions will cause temperatures to increase rapidly, sea levels to rise quickly, physical “tipping points” to occur suddenly, or dramatic human responses to these changes that include mass migration and international conflict. The case for using a low discount rate to determine the SCC is, in many respects, similar to the case for investing in gold, or for purchasing life, fire, and other insurance policies that protect against major disruptive events. Furthermore, this rationale is endorsed in Circular A-4, in its explication, discussed above, of how a lower discount rate is appropriate in analyzing more uncertain or intergenerational potential costs and benefits of a regulatory action.

Comment Text: In future analyses, USACE would be justified in using lower discount rates and higher estimates of the SCC. Above, we explained that when the USACE completed this management plan, it complied with Circular A-4 because it chose a discount rate based on the best available data to it. To continue to incorporate the best available information in environmental impact reviews, USACE should use an even higher SCC, for four central reasons: * First, the discount rate should match the risk characteristics of climate change, meaning that it should be in the neighborhood of the risk less rate or possibly even lower; * Second, the monetized costs of carbon emissions should reflect the most up-to-date science, which suggests that the damages from climate change are worse than previously anticipated; * Third, the USACE should continue to include the global costs of climate change because implementing a global analysis leads other countries to reduce emissions, which benefits United States citizens and residents; and * Fourth, the uncertain and heterogeneous nature of future climate damages supports using a higher SCC value than that produced through current calculations.

Comment Text: Lastly, it is worth noting that Circular A-4 recommends that agencies use lower discount rates-between one and three percent-when an administrative action will have significant intergenerational effects. (Again, these suggested discount rates come from a higher interest rate environment so current values are likely lower than this one to three percent range.) According to OMB, uncertainty about the appropriate value of the discount rate for regulatory actions with intergenerational effects over a longer time horizon supports using rates different and lower than three or seven percent. Circular A-4 concludes that, to set a discount rate that treat[s] all generations equally and avoids devaluing the welfare of future generations relative to the current generation, an appropriate discount rate for actions with such uncertain, long-term costs and benefits is from 1 to 3 percent per annum. Because any agency decision related to climate change necessarily impacts future generations in uncertain, long-term ways, it was appropriate for the USACE to use a lower discount rate in this case, and it should use an even lower discount rates in future analyses.

Comment Text: Circular A-4 recommends conducting analysis with discount rates of seven percent and three percent. The higher discount rate was an approximation of the return to equities or private capital in 2003 and the lower discount rate was an approximation to the risk free interest rate then. As we explain below, the nature of the returns to carbon mitigation investments favor the use of the lower discount rate, possibly even one lower than the risk free rate. Further, the discount rate analyses set forth in Circular A-4 supports using a discount rate even lower than risk free rate to assess the present value of intergenerational costs such as those generated by climate change. It is important to note, however, that Circular A-4 is now dated with respect to its characterization of interest rates in that capital has become uniformly and significantly less expensive since 2003. Thus under the rationale of Circular A-4, the baseline discount rates should be lower. In fact, the government now estimates that long-term government bonds will generate a real rate of return of approximately 0.7 percent.⁴⁰ And, current OMB guidance documents reflect the fact that the risk-free discount rate has fallen toward zero. The result is that the Circular A-4 guidance would appear to recommend using a risk free discount rate of less than one percent. Future USACE management plans and environmental impact statements should too.

Comment Text: It should be noted that, in its SCC analysis, the USACE used a value of \$38 per metric ton of CO₂, denominated in 2007 dollars, and applied a discount rate of three percent. This likely understated the value of the SCC. As an initial matter, the USACE should value the cost of CO₂ in accordance with the current dollar value, i.e. 2016 or 2017 dollars, not 2007 dollars, as the rest of its calculations are based on current dollars. The USACE needs to be consistent in which dollars it uses, or it risk understating costs. Further, the central value [of \$38 per metric ton] is the average of SCC across models at the 3 percent discount rate. As elaborated below in Part III, using a proper discount rate is [o]ne of the most important factors influencing [the SCC] estimates, because [a] large portion of climate damages are expected to occur many decades into the future and the present value of those damages . . . is highly dependent on the discount rate.

Comment Text: Monetization provides much-needed context for otherwise abstract consequences of climate change. If the NEPA review for an agency action merely quantifies greenhouse gas emissions by metric ton, or only qualitatively discusses the general effects of global climate change, decision-makers and the public will tend to overly discount that individual action's potential contribution. Without context, it is difficult for many decision-makers and the public to assess the magnitude and climate consequences of, for example, an additional million tons of carbon dioxide. Monetization, on the other hand, allows decision-makers and the public to weigh all costs and benefits of an action and to compare alternatives using the common metric of money. Monetizing climate costs, therefore, better informs the public and helps "brings those effects to bear on [the agency's] decisions."

Comment Text: 9. The Corps Should Monetize Methane as well as Carbon and Adjust for Yearly Increases The Corps' use of an estimate of the social cost of carbon in its draft EIS is commendable. However, currently the Corps does not appear to be using the social cost of methane or the social cost of nitrous oxide. Additionally, the Corps seems to be using only a single estimate of the social cost of carbon, without considering how that estimate will grow over time or giving weight to higher estimates that better capture uncertainty, catastrophe, and risk aversion. For example, Alternative 2 identified in the EIS would increase carbon dioxide emissions by over 121 million pounds annually (about 55,000 metric tons), as well as several thousands of pounds more in methane and nitrous oxide emissions; by comparison, Alternative 3 (the option preferred by the Corps) would decrease carbon dioxide emissions by 8 million pounds annually (about 3600 metric tons). The Corps applied an estimate of the Social Cost of Carbon to partially monetize these effects, choosing the central estimate for present-year emissions at a 3% discount rate, or about \$38 per metric ton of carbon dioxide. Applying this metric to the Plan Alternatives' greenhouse gas effects, the Corps calculates that Alternative 2 would lead to climate costs totally over \$2 million annually, while its preferred Alternative 3 would save about \$138,000 in climate benefits annually.

Comment Text: Move Beyond a Single Estimate, to Account for Growing Damages over Time and Uncertainty The same calculations discussed above further suggest that these climate effects would occur on an annual basis. However, the Corps has

chosen only a single estimate of the social cost of greenhouse gases: based on the calculations, the Corps has chosen an estimate appropriate for roughly present-year emissions. The social cost of greenhouse gases in fact increases every year. Because carbon dioxide accumulates in the atmosphere over time and climate damages escalate as temperature rises, a ton of carbon dioxide emitted next year is marginally more damaging than one emitted today, and so the social cost estimates rise over time. Even if it not feasible for the Corps to calculate the entire future stream of greenhouse gas effects over the years, discounted back to net present value, the Corps should acknowledge that it is only monetizing greenhouse gases for a single year, and that increased emissions would be more costly and reductions would be more beneficial in future years. Finally, the Corps should acknowledge that there is a range of social cost of greenhouse gas estimates, including a 95th-percentile value that captures uncertainty, risk aversion, and the potential of catastrophic outcomes.

Comment Text: Second, the chart employs different metrics for different impacts, complicating how the impacts are weighed within and among the alternatives. Below the two lines addressing species objectives, the chart exhaustively lists monetized impacts to human considerations. However, impacts to environmental factors are treated on a different scale using numerical indicators ranging from - 2 to 2. For example, the chart shows that Alternative 2 is the only alternative which would increase program expenditures, but it is also the only alternative with a positive Regional Economic Development (RED) value. Additionally, no other alternative besides Alternative 2 would offer "+2" to both "Fish and Wildlife" and "Other Special Status Species." How these different factors are weighed against each other is a mystery which the MRRMP-EIS never explains. Third, there are no summations of monetary or non-monetary values that would allow the alternatives to be compared in the aggregate. For example, the only characteristic of the chart which clearly distinguishes the preferred Alternative 3 from the others is the chart's color scheme. Alternative 3 has more green boxes and fewer red boxes than the other alternatives, but this does little to harmonize the convoluted metrics of the chart. The Executive Summary is supposed to enable the public to understand the project without reading the entire MRRMP-EIS, but the inconsistencies between the Executive Summary's graph and the purpose and need statement show how it fails to do so.

Comment Text: Section 3.12.3.5 - Alternative 3 - Mechanical Construction Only We agree that the basic impacts of Alternative 3 are reduced, relative to the No Action alternative at the outset of the management actions. In general, Alternative 3 results in the least negative impacts. However, because it still contains a provision for adjusting flow regimen, and because of the broad negative impacts of higher flows, and the possibility that annual pulses can still be adopted under the adaptive management process, Alternative 3 can still be very damaging to stakeholders. But it strikes a better balance between promising species recovery actions and negative consequences. If it eliminated the potential for spring pulses it would be the only acceptable alternative. All economic conclusions and modeling on Alternative 3 are inaccurate and incomplete due to the failure to provide robust and accurate modeling

and impact data on interior drainage. This alternative is unacceptable because no one knows what the impacts to NED, RED and OSE will be since the DEIS stipulates that economic analysis of the floodplain could not be completed. Translation of the impacts to the four sample sites to the rest of the floodplain was not even attempted and extrapolation from the four sites to other levee areas was not feasible since the hydraulics, hydrology and drainage varies between sites. However, given that no alternatives exist outside the six offered, we believe this alternative is the least unacceptable of the six alternatives.

Comment Text: 4. Overall economic impacts are substantially understated and modeling limitations are not delineated. We believe much of the understatement of economic impacts is due to the truncated nature of the modeling. Inadequate and incomplete resources were allocated for the modeling process and time constraints further truncated the process. The synergistic effects mentioned in point three above clearly show the effects analysis to be understated. The modeling limits itself to the loss of production on lands predicted to be acquired and does not include transportation, infrastructure, energy, water supply and the effects of economic multipliers from those impacts. These omissions and the limitations of modeling should be clearly delineated in the DEIS. The same level of resources, measurement and analysis should be applied to economic impacts that are applied to species impacts.

Comment Text: The MRRMP-EIS provides "fundamental" and "sub objectives" for each species, but summarizing them as part of the purpose and need statement itself would properly narrow the project's goals and the means of accomplishing them. As a result, ESA goals would be clarified and prioritized over human consideration impacts. The Corps could then use a chart to compare the relative effectiveness of each alternative in accomplishing those goals. For example, the chart could display how Alternative 2 "exceeds" the goals for the piping plover and interior least tern, along with how each alternative is projected to affect pallid sturgeon recruitment. The chart could truncate human consideration impacts into a single intelligible value for each alternative, and allow the body of the alternatives analysis to explain in more detail how each alternative affects those economic interests.

Comment Text: The modification to the DEIS is premature. Because modeling has only been completed for four representative levee sites, I can't be confident in the risks of any of the alternatives. While I believe Alternative 3 provides a better balance between my farming operation and species recovery, I cannot support any flow modification in Alternative 3 or any of the other alternatives from going forward until economic and hydrologic modeling is completed for the entire floodplain. I have too much capital at risk each and every year to simply not know what the impacts to my operation will be. I and THE TAXPAYERS deserve better from the Corps!

Comment Text: It also does not account for what activities may be implemented in the future relative to bed degradation which may be influencing model results. This is a complete disconnect with reality because riverbed degradation already requires winter flows much higher than those theoretical Master Manual flows. Current, actual water releases should be used for this baseline analysis. For instance, it requires approximately 10,000 cfs of additional water releases at Gavins Point today to maintain the same stage/elevation

at Kansas City than the release that was required when the Master Manual was drafted. Those lower flows were targets mentioned in the Master Manual, but do not reflect current reality. This approach undermines the accuracy and credibility of the DEIS as it fails to recognize simple reality and skews the modeled result in a way that makes it completely inaccurate and unreliable.

Comment Text: Section 3.15.2.11-Cumulative Impacts This section concludes that navigation could experience adverse impacts from low-summer flows and states the following: Adverse impacts could result in the reduction of the navigation season length for years with the low summer flow, and the potential reduction in service level provided that could occur in the years with the spawning cue pulse. When combined with other past, present and reasonably foreseeable future actions, the cumulative impacts on navigation associated with Alternative 2 would result in a large reduction in navigation benefits. The majority of the relatively large, long-term adverse impacts would be caused by the low summer flow which would shorten the navigation season and prohibit navigation during the important months of the year. While shippers may be able to plan around the low summer flow period, the reliability of the of the Missouri River would be reduced and shippers would begin to transition to other modes of transportation. Over time as more shippers switch to other modes, the overall navigation benefits on the Missouri River would be largely reduced.

Comment Text: 3.10.2.9 - Cumulative Impacts This section is troubling from several perspectives. For the first time in the entire land use section, there is recognition that many factors beyond land acquisition impact economic and social effects. But that mention is done only in the context of attempting to downplay the potential impacts of the alternatives. The DEIS is attempting to imply that concerns around impacts from management actions are trivial because Impacts to agricultural production can result from USACE activities and programs as well as many other policies, programs and economic influences. Thats like saying the fish and the birds could become extinct due to natural causes just like the dinosaurs so dont worry about them. The obvious bias toward characterizing the impacts as barely worth mentioning is troubling. The only action that was studied is land acquisition, and at best, that was an abbreviated study. But after a cursory review of land acquisition, and without yet knowing what the eventual management actions will entail because of the Adaptive Management approach, the DEIS concludes impacts are negligible. Further, it adds the observation that bad things can happen as the result of causes other than management actions. The cavalier and arrogant disregard the DEIS displays toward valid concerns and objections has no place in decisions that will impact the livelihood and safety of many generations to come. It is wrong-minded and in profound conflict with what the Federal government purports to call a collaborative and fact based approach. The DEIS representation of land use impacts is inaccurate, incomplete and unworthy of the hard work and sincere effort that stakeholders have put forth to recover the species.

Comment Text: Section & Page Number: 3.7, p. 3-181 Comment: With the increasing presence of Zebra Mussels in the Missouri River, facilities with freshwater intakes may use chlorine as a form of control/treatment to prevent system damage. This could result in wastewater discharges with higher chlorine content, which could increase chlorine interaction with trihalomethanes from mobilized organic matter. Therefore, it is important to recognize there are emerging risks to recovering the pallid sturgeon associated with Zebra Mussels and other ANS. The risks include modification to substrate, changes in ecological trophic status, and additions of pollutants and poisons into the system to combat ANS.

Comment Text: While a focus on water quantity is important, understanding the impacts of water quality is critical as well. Significant oil and gas development has occurred along North Dakota's portion of the Lower Yellowstone River and Missouri River, from the Confluence to Lake Sakakawea (known as the Williston Reach). More than 20 oil wells and numerous pipelines line the active floodplain, and are occasionally submerged during periods of high river flow or high lake levels. In 2013, approximately one million gallons of oil and saltwater spilled onto the landscape from more than 450 uncontained leaks. Protection from spills is rather limited, with most attention focusing on the impacts to people rather than wildlife. If a domestic or agricultural water user within 0.5

mile of oil or gas activity or one mile of a well site has "disrupted or diminished" water quantity or quality, the owner is entitled to recover the loss from the oil and gas company.

Comment Text: The EIS does not adequately address potential cumulative impacts from groundwater use, oil and gas production and grazing (Table 3-1). In the EIS, the Corps makes the assumption that actions taken on the land and use of groundwater are not relevant to the recovery of the pallid sturgeon. The science does not support this assertion. Additionally, the cumulative impacts analysis finds that depletions, snag removal, floodplain grazing and pasturing, oil and gas and groundwater withdrawals do affect fish and wildlife habitat, other special status species and water quality. Given this conflict between the effects of land use and groundwater on fish and wildlife habitat, but exclusion from impacts to pallid sturgeon, the Corps should consider: -Assessing the potential impacts of spills from the oil and gas industry on pallid sturgeon survival. -Provide evidence that pallid sturgeon survival is not impacted by surface water-groundwater interactions and thus are not affected by groundwater use. -Provide evidence that pallid sturgeon and their primary prey are not impacted by snag removal. -Provide justification for why pallid sturgeon would be impacted by floodplain development but not animal grazing in the floodplain.

Comment Text: 7) The Corps should re-examine the cumulative impacts of watershed use on the pallid Sturgeon Navigation is given a disproportionately high weighting. The Corps maintains reservoir releases to support navigation south of Sioux City, Iowa to maintain a navigation channel measuring nine feet deep and 300 feet wide. At one time the Missouri River supported regional or national transportation of commercial products, but since 2000, sand and gravel has represented greater than 85 percent of the commodities shipped on the Missouri River, which only travels as much as 10 miles. For example, sand and gravel dredging supports primarily home construction and state transportation department and is the primary reason for these short navigation trips. As shown in Figure 3-58 of the EIS (below), navigation for commercial purposes declined drastically from the 1980s to today. The Corps should consider this change in their reservoir allocations and whether the change in use is reflected in the authorizing purposes. Navigation now only serves local interests, and the proportion of use for navigation could be better used for decision-making.

Comment Text: Fish Stocking and System Alteration South Dakota requests the following statement in Section 3.3.2.11 be removed from the MRRMP and EIS as it is unsubstantiated. Past fishery stocking and management has caused a reduction in the abundance of native fishes from competition and inadequate amounts of biological resources available to support both populations; changes to the food web; and the introduction of pathogens. Citations for scientific journal articles and USAGE documents in Section 3.3.2.11 of the MRRMP and EIS support statements regarding how past USAGE actions, including construction of the Missouri River mainstem reservoir system and the BSNP, resulted in significant adverse impacts to pallid sturgeon. These include creation of physical barriers to migration, interference with the larval drift process, preventing access to formerly used habitats, and changes in water quality. Additional references are cited to support statements that the decrease in sediment load has been associated with decreases in turbidity that might directly affect native fish fauna. They also indicate that channelization and bank stabilization on the Lower River have altered habitat complexity and diminished floodplain connectivity. Both of these factors are likely to have substantive effects on productivity and species distributions throughout the river. However, there is no support for the statement that fishery stocking and management has caused a reduction in native fishes. Prior to system alteration by the creation of the mainstem reservoir system and the BSNP, native predatory fish species existed and many of those species, like channel and flathead catfish, continue to exist and thrive in the highly modified Missouri River ecosystems resulting from USAGE actions. The majority of the predators currently in riverine sections of the Missouri River are native species. It is in these riverine sections that native species, which formerly composed the prey base for pallid sturgeon, would be most likely to occur. The reason that the native prey fish component of the river is lacking is the complete alteration of the natural river ecosystem, not stocking predatory fish species in reservoirs where native prey fish production is unlikely to occur.

Comment Text: Agriculture, for a time during the active Conservation Reserve Program, actually increased the size of wetland acreage, but replaced the active and dynamic primary production (from an ecosystems perspective) of short grass prairie lands with monotonic row crops. On some reaches of the river, this conversion of grassland to cropland represented about a five fold shift in acreage, with magnified declines in ecosystem values for endangered and other species. Changes to the CRP, or to Flood Insurance Rate Maps can yield large changes, over time, to land use classification. And these changes appear not to be calculated for effects on floodplain connectivity or fish and wildlife habitat classes. or we have misread and misunderstood the text. All of these land use changes are studiable as GIS rasters and shapefiles, available to the public for download and transparent. Within the DEIS, we find no graphic descriptions for any of these changes, nor for the fish and wildlife habitat categories. The EPA- ICLUS v2 raster files project land use changes in a time-series to 2100. On the other hand, HEC-Ras modeled output was not used to create similarly comparative graphic products.

Comment Text: Alternative 4 contains a fall release designed for ESH which is possibly the most effective flow option so targeted. Other concerns are low water levels which might be by design or as an after effect in drought years. The Corps mentions the adverse impact of low flows, or flow variations and their potential disruption to intake pipes. But a greater threat to water levels and intake pipes is the ongoing degradation of the river bottom due to the self-scouring channel, reservoirs and BSNP configuration. The significant impact of this process was clearly demonstrated at a MRRIC meeting. The Corps mentions this in passing in the DEIS but does not include it as a backdrop condition when considering alternative impacts. It is not included in comparison charts, so it may

seem to the public that the alternatives represent a significant impact, when in fact, the ongoing background degradation is the force that will actually impact any use. This does not help the public make a meaningful comparison.

Comment Text: Alternative 5 - The League has concerns with Alternative 5. This alternative is contrary to the natural historic hydrograph of the river. Alternative 5 would have large flow releases in the fall instead of the spring, as in the natural hydrograph. We

believe any habitat created through fall releases would suffer serious losses to wind and ice erosion over the winter. This would create short lived habitat that would be largely unused while least terns and piping plovers are on their wintering grounds far south of the Missouri River. We also have concerns with this alternative's potential impacts on pallid sturgeon and other native fish species, with such a large release at an unnatural time of year for the Missouri River.

Comment Text: Section & Page Number: 3.4.2.8, p. 3-102 "Tern and plover population dynamics following high flows in 1997 and 2011 indicate that sufficiently high flows produce population increases in subsequent years. The spring emergent sandbar habitat-creating reservoir release modeled as part of Alternative 4 would have longterm, relatively large beneficial impacts from the creation of new sandbars that could occur following flows." Comment: First, this statement contradicts the conclusion of Section 3.2.2.4, which said that Alternative 4 would not have significant impacts on geomorphology. The statement says that the release would have long-term, relatively large beneficial impacts from the creation of new sandbars. Second, the long-term benefit of the ESH-creating release would only last until the sediment supply was exhausted, or for the inter-dam reaches, until all of the sediment was flushed into the reservoir deltas. Third, the ESH-creating release would have an adverse effect by increasing the flood risk of birds nesting on sandbars. When discussing the effect of the spawning cue releases for Alternative 2 (Section 3.4.2.6, page 3-101) and Alternative 6 (Section 3.4.10, page 3-104), this risk of flooding nesting birds is recognized. It should also be recognized for Alternative 4. These comments also apply to the fall ESH-creating release (Alternative 5), which is discussed in Section 3.4.2.9 (page 3-103), with the exception of the comment on flooding nesting birds. The fall release as described would occur after nesting season.

Comment Text: Section 3.4.2.5, Page 3-100 - No significant, adverse impacts are anticipated under Alternative 1; however, it appears Alternative 1 would not meet the 95% chance of persistence over 50 years. Since the last dam on the Missouri system reached full capacity in 1967 (see page 3-14), which happens to be 57 years, and the plovers have maintained a population for the entire period should cause a re-evaluation of the modelling done for the DEIS to that determined that Alternative 1 (i.e. current management plus 107 acres of ESH created habitat) does not have a 95% chance of population persistence for the next 50 years. Again the plain

facts do not support the modelling results. Since the first constructed island was completed in 2004 and the flood of 2011 washed out all constructed islands it is difficult for a reader to follow just how the construction of ESH would have changed the number of birds today or why it is necessary into the future.

Comment Text: Section 1.5.2, Page 1-24, Sub-Objective 2 - Concerning a 95% modeled probability that at least 50 birds will persist for 50 years (Northern and Southern Regions). Piping plover populations continue to exist on the river with fairly stable or increasing numbers (see 2015 Annual Report) despite the construction of dams on the Missouri River in the 1950s and little or no nesting in on the Missouri River or associated reservoirs in years like 1997 and 2011. Therefore modeling the Missouri as two separate populations that have little or no interaction and holding emigration and immigration as steady and equal in the models obviously does not take into account the reality of the bigger metapopulation influence and has some limitations. How those limitations affect the persistence probability needs to be explained. Likewise if acres of ESH are to be used as a surrogate there should be a simple graph or table that demonstrates the historical relationship of plover populations to acres of ESH in the past to justify the proposed methodology.

Comment Text: Interior least terns lay eggs on unvegetated sandbars. Periodic flooding of the river creates the sandbar habitat needed by the terns. Restoring sandbars along the Iowa section of the Missouri River will help restore the populations of these birds. Like the interior least terns, piping plovers lay eggs on sparsely vegetated sandbars. Restoring sandbars will help restore the populations of these birds.

Comment Text: It should also be noted that only five economic models on human considerations were presented to the ISETR for review and evaluation. The ISETR is still waiting on eight other sets of economic models on human considerations. When pressed by MRRIC members for the impacts and outcomes of the human consideration navigation model, the ISETR panel admitted that they do not have the expertise to understand how this model affects transportation costs, rail loads, infrastructure impacts, and water-compelled rates. The expert panel admitted that the navigation model was too technical for them to understand. In response to a question as to whether the ISETR was comfortable with the analysis of water-compelled rates in the navigation model, the leader of the ISETR said, We dont know what these terms mean-water-compelled rates, transportation savings-these terms are very confusing to us. We are not transportation economists. The leader of the ISETR panel stated in November 2016, We are going to have to punt on the navigation model. This answer was in response to a question of whether the ISETR was confident in the Corps navigation model regarding the impacts of the alternatives on Mississippi River navigation. The ISETR stated that that the Technical Report on navigation accompanying the DEIS will be much easier to understand. Despite professional concerns, the ISETR recommended that the Corps proceed with these models for use in the DEIS.

Comment Text: This conjures up images of vast areas devoid of habitat and wildlife vulnerable to the pillaging of private owners. This is not a minor point of contention. It is indicative of a pervasive attitude that things constructed by man and beneficial to man are harmful to all things natural and good. The lands are unprotected! By promoting this mindset and inflaming attitudes, the DEIS actively damages the cooperation and collaboration between stakeholders. Privately owned lands are anything but unprotected. In addition to substantial private and unreported efforts by private landowners for which national statistics are unavailable, the NRCS offers small incentives for a wide range of conservation activities on private lands that are tracked. The Conservation Reserve Program (CRP), the Conservation Stewardship Program (CSP), the Agriculture Conservation Easement Program (ACEP), the Regional Conservation Partnership Program (RCPP) and the Watershed Rehabilitation Program (WRP) are just a few of the NRCS sponsored efforts to improve conservation, habitat, water quality and provide a host of other environmental benefits. The CSP program alone has enrolled over 70 million acres, much of it in the Missouri River Basin. Landowner stewardship interest has been so high, in fact, that Congress had to set a limit on the number of acres that could be enrolled in both CSP and CRP.

Comment Text: 3.10.2.4 - Alternative 1 - No Action The economic modeling does not account for the impacts of management actions on other critical factors like transportation, traffic congestion, energy costs, water supply costs, etc. Individual economic entities do not exist in a vacuum. Its entirely possible that a seemingly inconsequential impact could be the difference between profit and loss and therefore survival or failure. It can mean the difference of whether a farmer can purchase new equipment, a fertilizer dealer can offer competitive input prices or whether a power company must raise rates. While difficult to model accurately, the failure to even consider those impacts brings the whole of the economic analysis into question. As stated earlier, management actions like changing flow regimens can substantially impact balance sheets and production.

Comment Text: Several of the proposed alternatives could have major impacts on Lakes Sakakawea and Oahe. Under these alternatives, the level of the reservoirs could fall an additional 5-7 feet. The lakes may not refill for years depending on precipitation and runoff. We feel this could potentially cripple the recreation industry, as access to boat ramps could be restricted and forage and game fish spawning would suffer (V3-pages 197 & 202). The AMP (AMP 2-page 210-211-Table 19) refers to steady to declining reservoir levels during the bird nesting season. While this could be beneficial to some species, this action would have detrimental impacts to forage and game fish recruitment on the reservoirs and drastic impacts on the recreation industry. We urge the Corps to always carefully consider the impacts to recreation when implementing recovery actions.

Comment Text: Again, the DEIS only mentions land acquired and taken out of production instead of addressing the far more damaging impacts of management actions. But this time the DEIS adds an interesting twist. First it points out that every acre that is acquired to create fish habitat will be taken off the rolls of productive land that could be flooded, thus eliminating it from flood risk. Somehow it has become logical to think that putting land underwater permanently eliminates the risk of flooding on that land. We hope this convoluted thinking is not expanded to the idea of taking all lands out of production so that no agricultural damage can be attributed to flooding. The analysis does not mention the negative impacts to interior drainage from Alternative 1 and again

obfuscates the real damages to land use predictability, crop losses due to delayed or prevented planting or the negative impacts of spring and fall flow rises or summer low flows. The analysis is wholly incomplete and has little or no value because of the exclusion of interior drainage analysis.

Comment Text: To provide accurate predictions from a relative standpoint, the modeling must be complete. In fact, we asked early on in the MRRIC process that the proper resources be deployed so that comprehensive econometric modeling could be utilized. Those resources were not allocated and the truncated version that was used is almost worse than not doing any modeling at all because of the inaccurate perceptions and conclusions it creates. For example, when we pressed for modeling of navigation outcomes and impacts, the expert panel concluded they simply didnt have the expertise to even begin to model how navigation affects transportation costs, rail loads, infrastructure impacts, public safety, etc. Yet the DEIS infers the economic study is adequate and very specific predictions about sales, jobs and tax revenues are presented. The modeling is woefully inadequate and the economic analysis is so limited in scope its not possible to say if its even directionally accurate. In the process of creating a model with appropriate scope and expertise, we would have had the opportunity to investigate and better understand the degree to which certain management actions will impact the basin and land use in general. Additionally, there would be at least some level of accuracy to the relative impacts of the alternatives. But the modeling is so severely truncated we dont know what the relative impacts will be, nor has the process identified all of the issues that need to be considered. That said, it is equally illogical to consider the current review and comment period as definitive in its ability to identify economic and social impacts of management actions.

Comment Text: 5. Empirical results imply scientific analysis and the ability to predict specific outcomes. This is misleading. All models, even those that attempt to encompass the maximum points of cause and effect, are subject to data and assumption errors and they require continual recalibration. For example, in the DEIS Land Use and Ownership Technical Report, inclusion of modeling data is presented as empirical fact. The report cites: the change in employment relative to alternative 1 for all acquired lands in crop production is 18.3 additional jobs. This infers economic modeling creates precise science. Not 17 jobs, not 19 jobs, but 18.3 jobs. The

economic impacts of management actions in the basin are not nearly as predictable as the DEIS tries to convince us they are. It is concerning that the DEIS contains no mention of the confidence level the public should put in economic modeling, nor does it specify the hurried, truncated and resource limited efforts of modeling of the six alternatives. This omission of serious and detailed caveats indicates that the process is tainted by substantial ineptitude or is deliberately fashioned to obfuscate the magnitude of the economic impacts of the six alternatives. The DEIS does not specify a robust process for ongoing analysis of economic impacts of adaptive management actions. Moreover, a culture that assumes scientific validity of economic predictions can lead those managing the adaptive process to take actions that cause substantial negative results because the economic science indicates the economic hardships they create will be negligible. Or, they may fail to take actions crucial to the species recovery if the models incorrectly predict the economic consequences are too severe.

Comment Text: Section & Page Number: 3.4.2.12, p. 3-104 Comment: The first paragraph of this section describes how the dams have modified river flows to the detriment of the piping plover and least tern by limiting sediment supply and maintaining higher flows during the summer, which increases the potential to inundate nests. It is agreed that the dams shut off the sediment supply to the river and affect the sustainability of sandbar habitat. This conclusion, however, completely disregards the dams' influence on the historical hydrograph that is a benefit to the birds. The dams have greatly reduced the once-normal floods that occurred due to plains and mountain snowpack runoff. Piping plovers arrive on the Missouri River around mid-April every year, hatching occurs within late May to early July, and they begin to leave the breeding grounds as early as mid-July. The plains snowpack normally melts around March and April and mountain snowpack typically melts between May and July. Before the dams, runoff from these two snowmelt events caused an increase in flow on the Missouri River during the same critical breeding time period for the piping plover. The effects analysis by Buenau (2015) shows that the existence of the dams, with no operations, resulted in a lower extinction probability for the piping plover than no dams at all. Comment Text: Tributaries along the Missouri River are prone to loss of water with drought and groundwater withdrawals. These changes in hydrology could impact flows in the upper Missouri River. Streams surrounding Lake Sakakawea and in the Powder River Basin are draining, and may go dry as Groundwater declines. Additionally, the region south of Lake Sakakawea is an important groundwater recharge zone. Groundwater is similarly limited with the nearest aquifer, Fox Hill, currently losing 1-2 feet per year. Though much is known about the aquifer itself, the impacts of groundwater withdrawals on rivers, streams, and wetlands remain poorly understood.

Comment Text: To highlight the unreliability of the models used to forecast rainfall events, the National Oceanic and Atmospheric Administration (NOAA) Weather Prediction Center routinely verifies the accuracy of Quantitative Precipitation Forecasts (QPF) the agency produces and uses for National Weather Service river forecasting operations. Verifications comparing forecast precipitation to observed precipitation have shown accuracy to be as low as 10 % in predicting the amount of precipitation that will occur, as well as where it will occur. Forecasted precipitation may not be close to the observed total, and may not occur where it was forecasted. Therefore, the accuracy of forecasted runoff within the drainage area of any specific reach of the river is uncertain at best.

Comment Text: Altering the flow will have negative effects on drainage and infrastructure near and far from the river. This is clearly evident from the 2011 flood where the effects are still a problem from a fiscal and hardship issues. Several drainage and levy districts are concerned about the tax levy's that were added to property taxes on the repairs to levy's and drainage districts might happen again. Also, everyone is worried about structural integrity of levy's since the 2011 event. Many of the fish, birds, habitat and infrastructure that you were trying to save were devastated. We feel the management of the river for flood control and drainage should be upmost importance.

Comment Text: The USA CE, in concert with the State, must develop guidance on how mitigation in the connected Missouri River Yellowstone River ecosystem will avoid jeopardy to Pallid Sturgeon as well as mitigate for impacts to other native fish and wildlife species. This should be included in the alternative analysis of the MRRMP-EIS prior to its finalization. Mitigation efforts could easily be established as part of the SAMP and their inclusion could be justified as Level 3 and Level 4 studies in answering Big Question 2 (Flow Naturalization and Productivity), Big Question 3 (Temperature Manipulations at Fort Peck), and Big Question 5 (Passage, Drift and Recruitment). Doing so would provide consistency with the goal of the Missouri River Recovery Program to create a sustainable ecosystem supporting thriving populations of native species while addressing major impacts of current and past river uses.

Comment Text: 4. Due to channel degradation and hydroelectric peaking at Fort Randall Dam, the river downstream of the dam experiences large elevation fluctuations that can dewater aquatic habitats. This can result in impacts to primary and secondary production and ultimately the aquatic food web. If hydroelectric peaking is continued during flow pulse events, the dewatering effect could be exasperated. We recommend the Corp attempt to keep releases from Fort Randall Dam steady during any managed pulse to minimize the dewatering of aquatic habitats in the Fort Randall reach.

Comment Text: Since the closure of Garrison Dam over 60 years ago, over 570,000 acre-feet of sediment have been deposited in the upper portions of Lake Sakakawea (USACE 2014). Simply dewatering this depositional zone would not undo decades of sedimentation and restore a naturally functioning river. Aside from the questionable benefits to larval pallid sturgeon, significant drawdown of Lake Sakakawea would have devastating consequences to the fishery, recreation and local economies. Sixty years of fisheries research by NDGFD has confirmed that maintaining an adequate water level (absolute minimum of 1825 msl) and having a rising pool during the spring spawning and egg incubation period are critical for maintaining the number one most used fishery in North Dakota - Lake Sakakawea.

Comment Text: 2. South Dakota and Nebraska jointly manage the paddlefish population below Gavins Point Dam. A paddlefish snagging season is conducted during the month of October each year. Restrictions on areas where boats can fish are in place if water is flowing over the dam spillway. Initiating increased flows on October 17th will affect the area of river below the dam open to paddlefish snaggers, reducing opportunity and potentially paddlefish harvest. 3. High reservoir releases will likely have similar impacts as the spring release on the Lewis and Clark Lake walleye population. By late fall, abundance of young walleye is highest in the downstream section of the lake, and fall releases of 60,000 cfs would likely result in entrainment of a large percentage of these newly hatched walleye. The actual effect of such a release is hard to estimate because a fall pulse of that magnitude is rarely seen in natural systems, and current reservoir management prescribes for much lower releases in the fall. Although the impact of a fall release would likely be lower than of the spring alternative due to increased size of young walleye, both alternatives would result in decreased walleye abundance in Lewis and Clark Lake.

Comment Text: Another water quality concern is vegetation removal on ESH. The DEIS (V2-page 121) states that herbicides could enter the substrate when vegetation is removed during vegetation management operations. Even if approved herbicides are used, we fear potential impacts to birds, mammals, and invertebrates could occur. We are also concerned that the potential impacts from aerial spraying and herbicide drift to fish and wildlife (V2-p197). The League would like to see much more research on the possible impacts of agricultural pesticides to determine if any of these chemicals are influencing recruitment of pallids or their prey species in the lower river. The levels may not exceed water quality criteria, but may be too high for the pallid sturgeon or their forage species (V2-page 194).

Comment Text: Alternative 5 - The League has concerns with Alternative 5. This alternative is contrary to the natural historic hydrograph of the river. Alternative 5 would have large flow releases in the fall instead of the spring, as in the natural hydrograph. We believe any habitat created through fall releases would suffer serious losses to wind and ice erosion over the winter. This would create short lived habitat that would be largely unused while least terns and piping plovers are on their wintering grounds far south of the Missouri River. We also have concerns with this alternative's potential impacts on pallid sturgeon and other native fish species, with such a large release at an unnatural time of year for the Missouri River.

Comment Text: Data from NDGFD shows that reservoir fishery health is also dependent on water levels. Correlation analyses of the total catch rate of young-of-the-year (YOY) fish (all Sakakawea) and environmental variables show significant positive correlations

between catch rates of YOY fish and spring rise, total rise, and the change in maximum water levels from the previous year (Table 3). These data indicate the importance of water level management to the overall reproduction of fish in Lake Sakakawea. [Table 3. Results of correlation analysis for the catch rate of YOY fish in frame and hill nets combined and environmental variables, Lake Sakakawea, 1972-2013] The importance of timely water level manipulation for fish and wildlife resource management cannot be over-emphasized, nor can the destructive capacity of untimely manipulation be underestimated. Information gained from more than forty years of Missouri River surveys and investigations can now be used to outline the methods and highlight the importance of a system approach to water level management as a tool to enhance fishery resources. Every attempt should be made to develop workable water level scenarios which will promote those objectives on a more frequent basis.

Comment Text: Bimodal Spring Pulse for Pallid Sturgeon Recruitment (Alternatives 2 and 6) A March pulse would occur once navigation releases were met at downstream target locations. The peak Gavins Point release would be two times the navigation release on the pulse initiation day, with potential releases for the March spawning cue being between 39,000 and 61,000 cfs. A second pulse would occur during May when water temperatures reach 16- -18 °C. The peak Gavins Point release would be two times the base release on the pulse initiation day. Releases during the May spawning cue would range from 50, 000-67, 000 cfs 1. Effects on the Lewis and Clark walleye population by the bimodal spring pulse will be similar to the effects stated for alternative 4. While the March pulse will likely have little effect on the walleye population, the May pulse component will result in increased entrainment of newly

hatched walleye. As stated earlier, walleye abundance in Lewis and Clark Lake is negatively correlated to water yield, and releases of 50,000-67,000 cfs in May would likely flush most of the newly-hatched walleye through Gavins Point Dam.

Comment Text: Spring Flows to Create Emergent Sandbar Habitat (Alternative 4) If System storage is at 42 million acre feet (MAF) or greater on April 1, natural flows creating 250 acres of ESH have not occurred in the previous four years, and downstream flow limits are not exceeded, ESH creating flows would be implemented on April 1 with a release of up to 60,000 cfs out of Gavins Point Dam, and as often as every 4 years. 1. Sandbar habitat-creating flows have the potential to severely impact the sport fishery of Lewis and Clark Lake. While other Missouri River reservoir fisheries generally respond positively to above average water yield, the small relative size of Lewis and Clark Lake results in a low storage ratio and detrimental impacts caused by high flushing rates. Walleye population abundance in Lewis and Clark Lake is negatively correlated to total water yield through Gavins Point Dam. The most likely cause for this correlation is the flushing of newly-hatched walleye from the lake through Gavins Point Dam during average to above average water yield years. Increased flows in April and May would likely have detrimental impacts to the sportfish population through increased flushing of newly hatched walleye through the dam. 2. A correlation exists between the average annual elevation of Lake Oahe and the amount of angler use and was used in some of the modeling for the Recreation Technical Report. However, major flow events result in degraded fishery quality and angler use a few years after their occurrence, resulting in low angler use even at high reservoir elevations. Major flow events have the ability to flush the majority of pelagic prey (rainbow smelt and lake herring) and Chinook salmon through Oahe Dam. Even if reservoir elevations are sufficient to allow good access to the reservoir after major flow events, the lack of available food resources results in the loss of the larger walleye from the reservoir due to starvation. This occurred after large flow events in 1997 and 2011 and it took Lake Oahe over 5 years to recover each time. The Chinook salmon population in Lake Oahe was severely reduced by the 1997 and 2011 flow events, and as with the walleye fishery, has taken over 5 years to recover from each event. Timing of flow events, with regards to stratification of the water column in Lake Oahe and fish distribution within the water column, is a primary consideration when predicting impacts of high flows on the Lake Oahe recreational fishery. 3. Decreasing elevation of Lake Oahe and Francis Case during prey and game fish spawning periods (April - June) is a concern as stable-to-rising elevations are important to the success of prey fish and sportfish spawning events and egg incubation. With Lake Oahe being the lowest of the big-three storage reservoirs in the system, a spring release to create ESH will certainly remove the possibility of favorable conditions for spawning during the year of the flow implementation. Lake Francis Case is a much smaller reservoir than Oahe and the lowest source of available water for adjustments to releases from Gavins Point Dam. The need for an immediate source of water to support flow-related management actions could affect the elevation of Lake Francis Case during

walleye spawning, thereby reducing the stability and quality of the walleye fishery, which contributes significantly to the recreation industry in South Dakota.

Comment Text: The Missouri River System Fisheries Management Plan identifies specific water management recommendations that are critical for maintaining a sustainable and productive fishery (Fryda et al. 2010). Select recommendations presented below would be at best vastly compromised or more likely never met under a significant Lake Sakakawea drawdown. The NDGFD, under no circumstance, could support such a Level 2 or above action in the MRRMP-AMP. Fishery Recommendations for Lake Sakakawea: 1. An absolute open-water minimum lake elevation of 1825 ft. msl for drought periods and 1832 ft. msl for all other years is recommended. Below these specified elevations, the following detrimental impacts occur to the fishery resource or affect its use: dramatic declines in reservoir productivity, a substantial loss of walleye and smelt spawning substrate (gravel/cobble) and coldwater habitat (for rainbow smelt and Chinook salmon); critically needed water becomes less available to the Garrison Dam National Fish Hatchery for production; and boat access/recreation use becomes limited. 2. Other than years in which severe drought or flood conditions prevail, a maximum lake elevation window of 1838 to 1846 ft. msl is requested in order to maintain flexibility in annual recommendations and to reduce impacts from wave erosion. 3. The spring water level rise must inundate good spawning substrate (i.e. cobble and/or terrestrial vegetation) by April 20 and continue to rise during spawning-incubation (April-May). A target increase of two to three feet between April 20 and May 20 should occur during a filling cycle. Even during a drawdown cycle or during drought conditions, a rising lake elevation should be attempted during this critical time period. Fryda, D. and S. Gangl. 2016. Angler Use and Sportfishing Catch Survey on Lake Sakakawea, May 1 Through September 30, 2015. ND Game and Fish Dept. f-2R-61, Study 4, Number 1. Fryda, D., F. Ryckman, R. Kinzler and P. Bailey. 2014. Aquatic Investigations of the Missouri Mainstem in North Dakota. ND Game and Fish Dept., Div. Rpt. 90. 105 pp. Fryda, D., F. Ryckman, P. Bailey, R. Kinzler and S. Gangl. 2010. Comment Text: Data collected by NDGFD over the decades have shown conclusively that a rising pool level and the lake elevation are the two strongest environmental variables that correlate with annual production of all young of year fish (Fryda et al. 2014; Fryda et al. 2010,). Lake elevation is also critical for the maintenance of cold water fish habitat in Lake Sakakawea. Low lake elevations in past drought periods have caused reduction/elimination of cold water habitat, caused hypoxia in the hypolimnion, and devastated the chinook salmon and rainbow smelt populations. Additionally, the headwaters region of Lake Sakakawea that would be dewatered is a critical rearing area for juvenile paddlefish. The Yellowstone/Sakakawea stock of paddlefish is one of the most scientifically understood paddlefish populations in North America. Extensive research has shown good inflows combined with high lake levels are crucial for recruitment to this nationally important self-sustaining paddlefish population (Scarnecchia et al. 2008). Lake Sakakawea is typically the most heavily utilized fishery in North Dakota and annually accounts for over 30 percent of all fishing effort in the state. In 2015 alone, anglers expended over one million hours of angling effort on Lake Sakakawea (Fryda and Gangl 2016). Expenditures generated by these anglers are vitally important to the regional economy. Significant drawdown of Lake Sakakawea would have major impacts to these economies due to impacted fish populations and poor to non-existent access caused by low lake elevations.

Comment Text: An examination of the 2011 months-long flooding of the Missouri River along Iowa's border is instructive. The flooding scoured holes, created backwaters and areas with reduced stream flow. All of this improved fish habitat, increasing survival of eggs and young fish, providing habitat for the juveniles, and allowing the fish to reach maturity. The next year, fishing enthusiasts reported catching larger and more fish than in prior years. The Iowa Department of Natural Resources conducted fish surveys in 2012. They reported increased numbers of paddlefish, channel catfish, northern pike, and shovel-nose sturgeon.³

Comment Text: Operations outside of the Master Manual have high probably of impacting water quality, a parameter not currently accounted for in the Water Supply Technical Report. Of particular concern is any flow regime(s) with the potential to create conditions optimal for cyanobacterial (blue-green algal) growth. With historical Missouri River operations falling within the defined constraints of the current Master Manual, little to no river water quality data exists for intentional and consistent operations outside of those defined constraints. Referring to Water Quality Technical Report, limited observed temperature data was available causing inaccuracies in modeled temperature changes for the alternatives and a loss of confidence in the data generated. What is known (and experienced with other source waters in Kansas) is that periods of reduced low flows result in slower and warmer waters conducive to blue-green algal growth. Nutrient loading on the Missouri River is more concentrated in Missouri RAC Planning Area and nutrient loading should be given more consideration in the EIS. Blue-green algae is harmful to aquatic life, can be costly for communities, impacting not only recreation, but public health and safety and is difficult to treat. These low flow impacts and the associated costs must be included in the EIS.

Comment Text: 3.7 Water Quality General Analysis: 1. The DEIS fails to evaluate water quality problems associated with low summer flow as contained in Alternative 2. Impacts and costs to water operators must be included. Specific Comments: 3.7 Water Quality, Alternative 2 Low summer flows within Alternative 2 would be harmful to water quality, especially in regard to cyanobacterial or blue-green algal growth. Because Missouri River water suppliers historically operate within the current Master Manual constraints, there is little water quality data that exists for operations outside of those constraints. We know that periods of low flows equate to slower and warmer waters conducive to the potential for the formation of cyanotoxins, which can be difficult to treat. Although no firm maximum contaminant level has been established by EPA, they agency has issued health advisories on this matter. At a minimum, treatment costs would increase under low flow conditions because of additional chemicals needed to treat the water.

Comment Text: We must take issue with statements in 3.7.1.3 concerning other pollutants. This paragraph addresses substances as pesticides. It states at Rulo, the pesticides&atrazine were present but not at levels that exceeded water quality criteria. Some utilities routinely treat for atrazine removal to meet the potable water contaminate level of a maximum of 3 ppb. Of further consideration is the use of average temperatures for the lower River. Utilities routinely experience high water temperatures during low flow periods coinciding with warm summer season. These high temperatures along with low turbidity normally associated with low summer flows create the condition for the potential formation of cyanotoxins. Although no firm maximum contaminant level has been established by EPA, Health Advisories have been issued by EPA. In accordance with EPA, Health Advisories, Missouri is one of the states, reviewing or developing an approach to address cyanotoxins in water, with others in various stages of development. (JAWWA Vol. 109 p. 42.) Anecdotally, some utilities have experienced Algae like blooms characteristic of cyanotoxin formation during previous

low flow summer periods. At that time, no attempt was made to analyze for toxins as methods are just being developed and no EPA requirements were in place. This is no longer the situation. We are concerned that any Alternative with low summer flows may create river conditions requiring, at the least, extensive treatment.

Comment Text: In spite of concurrence that Alternative 3 represents the best presented option, the State is concerned that in the process of constructing many of the Shallow Water Habitat practices, sediment is routinely removed from parts of the river and adjacent banks only to be placed back in the main channel of the river where it is flushed downstream. This practice is counterproductive to the goals of both the Iowa Nutrient Reduction Strategy and the Mississippi River/Gulf of Mexico Hypoxia Task Force, which call for significant reductions in the transport of nitrogen and phosphorus to the Gulf from our state. We believe that state and federal agencies should be held to the same standards as our agricultural and urban constituents with respect to reducing nutrient transport by way of our rivers and streams, and that the practice of placing nutrient-laden sediment into the river channel will only add to the challenge of improving water quality in Iowa and downstream. To that end, we request that any mechanical habitat construction be undertaken in a manner that avoids, to the greatest extent possible, deposition of sediment back into the Missouri River.

Comment Text: In 2012, US Army Corps of Engineers utilized water from the Kansas Reservoirs to protect nesting Least Terns and Piping Plovers on the Missouri River by calling for supplemental navigation support releases. There is significant investment in storage in the Kansas Reservoirs, (Milford, Perry, and Tuttle Creek) to meet the public's needs and the eight authorized purposes especially during drought conditions. Water from these Kansas Reservoirs should not be used to support the alternatives presented in the Missouri River Draft EIS that would impact Public Water Supply. Water Supply and Water Quality should be considered the highest priorities of the authorized purposes with substantial impacts to human considerations in the EIS.

Comment Text: The Corps fails to give adequate consideration of ecosystem services and that failure impacts their evaluation of alternatives. One example occurs in the Land Use and Ownership Environmental Consequences Analysis, Technical report pages 5-8. The Corps evaluates the impact of agriculture acres for federal acquisition. The Corps notes the loss of agriculture output if some

acres are taken out of crop production and points to the loss of taxes to the county, or land in the local levee association. But no consideration is given to the likely reduction in flood risk to those same neighboring acres when, due to those acquired acres, levees are set back, wetlands created, a channel widened and or floodplain connection is formed. Also the Corps fails to give adequate clean water services to those acquired acres, or any impacts on groundwater recharge.

Comment Text: Failure to evaluate the water quality problems with any summer low flow - Although the Corps is not recommending Alternative 2, the low summer flows associated with this alternative would be very harmful to Water Supply. Of particular concern is any flow with the potential to create conditions optimal for cyanobacterial (blue-green algal) growth. With historical Missouri River operations falling within the defined constraints of the current Master Manual, there is little to no river water quality data for operations outside of those defined constraints. In the Water Quality Technical Report, limited observed temperature data was available, which caused inaccuracies in modeled temperature changes for all alternatives and a loss of confidence in the data generated. At the very least, treatment costs would increase because of additional chemicals needed to treat the water. It is known (and experienced with other source waters in Kansas) that periods of reduced low flows result in slower and warmer waters conducive to blue-green algal growth. Blue-green algae is difficult to treat. It can be costly for communities, affecting not only recreation, but also public health and safety. These low flow impacts and the associated costs must be included in the EIS. The Corps should include some consideration of this possibility in the Adaptive Management Plan. WaterOne has provided examples of sampling protocol on this issue during review of the AM plan.

EC700 Environmental Consequences: Water Supply (Substantive)

Correspondence Id: 38 **Comment Id:** 628360 **Coder Name:** jgutierrez

Comment Text: WaterOne spent \$2.4 million on permanent low water pumps for less than half of its intake capacity in 2003. The capital costs would be much greater than this today and the economic analysis should assume that those types of costs will have to be considered instead of renting pumps. The costs are severely understated. It is very likely that situations would occur that will leave some communities without water supply for days. The report makes no estimated cost to those communities when they have no water supply. The cost impact to Cleveland in 2003 when a regional power outage left 1.5 million people in the city without water for two days was in the hundreds of millions of dollars when you consider the factories and businesses that were shut down. An outage would mean a loss in fire protection, the inability to cook, bathe or even flush toilets. A shutdown of critical facilities like hospitals and an increase in the risk of disease outbreaks without a water supply, a water supply outage becomes a state and federal disaster.

Comment Text: Section 3.18.2.4 - Alternative 1- No Action Here, the DEIS states: The modeling results show that 33 of the 55 intakes would experience on average 57.1 days when water surface elevations would fall below operating thresholds. In addition, 21 of the 55 intakes would experience on average 14.7 days when water surface elevations are below shut-down elevations under Alternative 1. The DEIS constitutes the first public report documenting that Missouri River basin communities could be in danger of losing their water supply. The Corps must address this catastrophic scenario for those that rely on the Missouri River as their water source. Further, the DEIS states: the impacts modeled do not account for the ability of water management to adapt to changing conditions on the system to serve authorized purposes, such as water supply. It also does not account for what activities may be implemented in the future relative to bed degradation which may be influencing model results. Another very alarming statement found on the same page is: The project team did not attempt to evaluate the cost of intake modification that may occur due to bed degradation or prolonged drought conditions. The NED analysis states: focused on actions that water supply operators can adapt by using different-sized portable submersible pumps. Water supply operations are a mission-critical, non-stop business and it would be unacceptable and irresponsible to wait until water levels are at critical levels and then hurriedly go out and rent pumps. The DEIS wrongly assumes there would be an adequate supply of pumps in the size and quantity needed to operate the 55 intakes on the river. Further, the DEIS makes the incorrect assumption that temporary pumps can easily be connected to Missouri River intakes, which they cannot. This is a head in the sand approach which must be corrected. The NED analysis details another incorrect assumption in the DEIS, stating that 55 water suppliers could acquire portable pumps for a cost of \$376,000 per year, which is very low and based upon inaccurate facts. Bed degradation already requires winter flows much higher than Master Manual flows. For example, about 10,000 cfs in additional releases are now required from Gavins Point to maintain the stage elevation at Kansas City than when the Master Manual was drafted. The DEIS fails to recognize this reality which skews the modeling results, making them inaccurate.

Comment Text: Section 3.18 Water Supply General Analysis: 1. Interruption of water supply for even one day would be disastrous for people who live and work in the Missouri River Basin. The Corps should quantify the impact of communities being without a water supply for a day and include such risk assessment in each of the DEIS alternatives and it must continue to place the congressionally authorized purpose of water supply among its highest priorities. 2. Public water suppliers rely on fixed intake

structures to divert water from the Missouri River and its major tributaries. These intakes rely on the channel created and maintained by the Bank Stabilization and Navigation Project (BSNP). Most public water suppliers have limited or no access to alternative water sources. 3. Water supply intakes were designed and constructed with the Corps advice, consent and approval. It is either extremely expensive or impossible to adjust these intakes to accommodate major changes in river levels. As management plan alternatives are considered, the Corps must make sure these intakes are capable of continuous operation. 4. The DEIS fails to recognize and address Missouri River bed degradation, which is impacting water supply intakes. The Corps has the key responsibility to correct this problem, which has taken place over the last 25 years. Regulatory cost of compliance must be detailed in the DEIS. 5. The DEIS is inadequate in identifying the current, actual operating and shut-down elevations for Missouri River water supply intakes. Some of the data used in the models appears to be inaccurate or incomplete. The Corps should undertake a systematic process to collect and verify data. 6. The DEIS wrongly assumes that water access problems can be solved by rental of supplemental pumps on a temporary, reactive basis.

Comment Text: Impacts Common to all ESH Creating and Spring Bi-modal Pulse Flows Alternatives 2, 4, 5, and 6 include management actions that involve large releases of water from the system. Some impacts to South Dakota stakeholders are common to all these actions. 1. Under these alternatives the large releases associated with the bi-modal spring pulses would require a large draw on storage from the mainstem reservoirs. If the timing of these releases coincides with lower reservoir levels due to drought, the

intakes for public drinking water and irrigation systems can be adversely affected due to falling reservoir levels. This could drastically increase pumping costs and potentially expose water system intakes. 2. Public drinking water systems can also face increasing turbidity as well as taste and odor problems associated with degraded water quality resulting from low reservoir levels. This not only increases the cost of treatment and, ultimately, the cost to the consumer, but also threatens the ability to comply with the Safe Drinking Water Act.

Comment Text: In addition, there are concerns with the method the Corps used to model the impacts of the alternatives on Water Supply. Flow requirements, which are much higher than the minimums mentioned in Master Manual due to riverbed degradation, especially in the Kansas City, Leavenworth and St. Joseph areas, should be considered. This was identified several times in the DEIS, including page 3-504 of the DEIS, wherein it states, the No Action Alternative does not reflect actual past or future conditions. Worst case scenarios of the Period of Record were used and hypothetical Master Manual minimum flows to create a baseline. Because of bed degradation, the minimum flows mentioned in the Master Manual could not and would not support the Water Supply Intakes on this stretch of the River. As a result, the Corps has assumed that the 33 of the 55 water intakes would experience 57 days below operating thresholds and 21 intakes would experience 14 days below shutdown elevations. This assumption is not reasonable to correctly estimate the impacts and costs. The Corps should reevaluate its approach and model realistic flow requirements to keep water supply intakes in operations at all times. Additionally, the Corps analysis of rental pumping submersible pump costs and sizes are unrealistic for a major utility intake.

Comment Text: Additionally, staff is concerned with the methodology used by the Corp in modelling the impacts of alternatives on the City Water Supply. It is staff's view that minimum flow requirements mentioned in the Master Manual did not properly model the impact of alternatives on the water supply intake due to riverbed degradation. Flow requirements for Kansas City, Leavenworth, and the St. Joseph area are much higher than those discussed in the Master Manual and should be revisited. This flaw in the model was admitted several times in the DEIS, including page 3-504 of the DEIS, where it was noted " ... the No Action Alternative does not reflect actual past or future conditions ... " The Master Manual uses worse case scenarios of the Period of Record and then used hypothetical Master Manual minimum flows to create a baseline. Because of bed degradation, the minimum flows mentioned in the Master Manual could not and would not support the Water Supply Intakes on this stretch of the River. As a result, the Corps has assumed that 33 of the 55 water intakes would experience 57 days below operating thresholds and 21 intakes would experience 14 days below shutdown elevations. This assumption is totally unacceptable. The Corps should reevaluate its approach and model realistic flow requirements to keep Water Supply Intakes in operations at all times. Additionally: the COE analysis of rental pumping submersible pump costs and sizes are unrealistic for a major utility intake as KCMO operates with a capacity of 400 MGD and average production of 100 MGD increasing to over 200 MGD during high temperature dry periods.

Comment Text: From the Technical Report, the Association would like to know where the Corps obtained its data on location and low water shut-off elevation of our River Intake pumps. The information on the size of pumps and costs necessary to draw water from the river are under estimated. Locating pumps larger than 7,000 gpm to rent will be a difficult task, especially if half of the members in this Association are looking for these large pumps to rent. It is doubtful that a utility would be able to receive these auxiliary pumps in time to prevent a water outage. If a water outage would occur, the State regulatory agency will most certainly require a Boil Order to be issued. Has the Corps looked at the power requirements to operate these auxiliary pumps and if there will generators available to supply power? The information presented on the cost of renting pumps seems too grossly under estimate the impact if water supplies are not able to pull water from the River. Again, the water utilities in this Association serve over 5 million customers daily and support billions of dollars of industrial commerce and services which depend on our ability to pump water from the Missouri River.

Comment Text: In both Reports, The Corps states there will be times where some intakes will not be able draw water from the Missouri River. This would be a catastrophe to any water utility who must provide water to its customers. The inability to pump water from the River would mean no fire protection, Hospitals, nursing homes, and dialysis facilities would not be able to provide service. Water is essential for public health and without it we would be no better than a third world country without basic sanitary conditions. Loss of water supply from the River, would result in billions of dollars in lost revenue due to businesses shutting down for safety and public health reasons in large metropolitan areas. If water interruption is expected to average 14.7 days, as stated in both reports, both the public and businesses would lose confidence in a utility to provide basic service and may relocate. The community would stagnate or the population would decline due to unreliable basic services. The reported NED and RED impacts, are grossly under estimated if a water utility is unable to provide water for 14.7 days, let alone one day.

Comment Text: From the Technical Report, we have serious concerns that the information you have presented may not be the most accurate on location and low water shut-off elevation of our river intake. Also, the information on the size of pumps and costs necessary to draw water from the river are underestimated as we have previously discussed this subject with a contractor. Locating pumps larger than 7,000 gpm to rent will be a difficult task, especially if many electric and water utilities along the Missouri River are having similar issues and looking for these large pumps to rent. It is doubtful that a utility would be able to receive these auxiliary pumps in time to prevent a water outage. If a water outage would occur, the Missouri Department of Natural Resources (MDNR) will most certainly require a Boil Order Notice to be issued.

Comment Text: The USACE has the obligation to meet all the Eight (8) Authorized Purposes, Water Supply being one of these Authorized Purposes. The Draft MRRMP-EIS affects not only the Missouri River but also the Mississippi River as approximately 60% of the flow of the Mississippi River comes directly from the Missouri River. Since our Utility has water intakes on both rivers, any change to flows directly impacts our ability to produce drinking water to our customers. We have serious concerns regarding flows and water quality about each of the six (6) alternatives proposed in the Draft MRRMP-EIS, and the data present in the December 2016 Water Supply Environmental Consequences Analysis Technical Report. In both documents, the USACE states there will be times where some intakes will not be able draw water from the Missouri River. If this were to occur at our Missouri and Mississippi River intakes, there would be a catastrophic effect for our Utility and jeopardize public health and safety to our customers. If water interruption is expected to average 14.7 days, as stated in both reports, residential and commercial customers would lose confidence in our Utility's ability to provide reliable, basic services which would likely result in relocation to a city with more reliable

water services. The reported national and regional economic development impacts are grossly underestimated if a water utility is unable to provide water for one day, let alone 14.7 days.

Comment Text: Section & Page Number: 3.18.2.5, p. 3-509 "In addition, 22 of the 55 intakes would experience on average 14.4 days when water surface elevations are below shut-down elevations under Alternative 2. While on average, these impacts would be small in nature, there would be some years when access to water supply, especially in the lower river, would experience larger impacts." Comment: Having water surface elevations below shut-down elevations is never a small impact, regardless of how large or small the population is that relies on that intake. Characterizing that effect as small in nature makes it sound trivial. During real-time operations, the USACE releases water above and beyond what is required by the Master Manual to keep intakes on the riverine sections of the Missouri River operable. For example, during the 2012- 2013 winter, releases were scheduled to be 12,000 cfs from Gavins Point, as specified in the Master Manual. Due to bed degradation and low tributary flows, actual releases were held at 14,000 cfs. The volume of water released from the upstream reservoirs collectively due to the increased flow was approximately 400,000 to 500,000 acre-feet. The EIS should acknowledge the actual operations of the Missouri River System by the USACE and quantify the impacts of the alternatives based on that operation.

Comment Text: Section & Page Number: 3.18, p. 3-500 - 3-524 Comment: This comment is a general comment in regards to the lack of Regional Economic Development (RED) analysis for the water supply evaluation. Because there was no RED analysis to determine the local effect on water supply, the whole evaluation is skewed in favor of the lower basin. It is understood that the population is higher in the lower basin, making total costs higher. However, this means that the costs are also spread out over a larger population. For smaller populations, like many of the communities in the upper basin, the cost for modifying an intake is spread out over less people. A RED analysis, or some kind of local analysis, would potentially paint a different picture when it comes to water supply impacts.

Comment Text: In both reports, the Corps states there will be times where some intakes will not be able draw water from the Missouri River. This would be a catastrophe to any water utility who must provide water to it's customers. While Sioux City does not have a direct intake on the Missouri, we have long stressed to the Corp, that our water supply is dramatically impacted by changes in river elevation. Sioux City not only provides water to our community but also augments the water supply of South Sioux City, Nebraska and Dakota Dunes, South Dakota. Sioux City's water supply impacts over 125,000 people. This water is used for drinking water purposes, fire protection, Industry supply and irrigation .The inability to pump water from the Missouri River would mean no fire protection, hospitals, nursing homes, and dialysis facilities would not be able to provide service. If water interruption is expected to average 14. 7 days, as stated in both reports, both the general public and businesses would lose confidence in a utility to provide basic service and could potentially choose to relocate to an area of the country that can constantly provide water service. Our community could potentially become stagnate or the population would decline due to unreliable basic services. The reported NED and RED impacts are grossly under estimated if a water utility is unable to provide water for 14.7 days, let alone one day.

Comment Text: Even Alternative 3, which appears to be the best alternative available, states that it would result in 22 intakes experiencing an average of 14 days below shut-down elevations (Section 3.18.2.6). No water utility would have enough storage or alternative sources to sustain itself for 14 days without a water supply. The Corps should therefore quantify the impact of communities being without a water supply for even a single day and include the cost of that risk in each alternative. Consumers would not be able to drink, bathe, cook, clean, or flush toilets. Schools and day care centers would have to close. Hospitals, nursing homes and health care facilities would be highly impacted. Fire protection would be lost, so office building and businesses would have to close. State and Federal government operations - including the Corps of Engineers - would be impacted.

Comment Text: Failure to define the duration and frequency of the events - Referring to Human Considerations Technical Report - Water Supply, Section 3.1 Paragraph 2 which describes using the period of record along with the minimum flow per the master manual as the flow condition. This worst case model scenario does not include how often the scenario occurs. For example, does it

occur every year or once every 25 years? The shutdown frequency was not defined and therefore the costs associated with the shutdowns was not calculated or estimated. The EIS needs to quantify how many times the events will occur and during what period they occur. The frequency of the occurrences and associated costs should be included in the final report for each alternative.

Correspondence Id: 122 **Comment Id:** 638468 **Coder Name:** jgutierrez

Comment Text: Failure to estimate costs of the alternatives accurately - The Corps has assumed that 55 Water Suppliers could equip themselves with portable submersible pumps at a cost of \$376,000 per year, see page 3-508. This estimate is extremely low and does not seem to be based on reliable facts. The cost of complying with every alternative in the DEIS is much higher than estimated. For instance, WaterOne spent approximately \$2.4 million in 2004 to purchase and install auxiliary pumps to cover just 50% of the pumping capacity for its Missouri River Intake. Even if one assumes that pump rental is a viable option, daily pump rental would be impossible. For every year that a low flow event might occur, the utility would have to rent the pumps for the entire season or perhaps the entire year. In addition to the pumps, the water supplier would need to secure additional equipment such as barges to support the pumps. Alternative 2, with low summer flows, would have the worst impact requiring both summer and winter rental costs. Every alternative except Alternative 3, would consume storage, which would increase the likelihood that the pumps would need to be rented for multiple years. These costs are not accurately reflected in the EIS.

Organization: WATERONE

Commenter: MICHAEL J ARMSTRONG **Page:** **Paragraph:**

Correspondence Id: 122 **Comment Id:** 638457 **Coder Name:** jgutierrez

Comment Text: Failure to quantify impacts to water supply operations - The DEIS assumes that if there are problems with access to water on the Missouri River that Water Supply intake operators can rent supplemental pumps on a temporary and reactive basis. Section 3.18.2.4 states that the NED analysis, focused on actions that water supply operators can adapt by using different-sized portable submersible pumps. To be blunt, this assumption is simply absurd. Operation of a Water Supply is a 24/7 mission critical business. The public is relying on Water Suppliers to provide them with water on a continuous and reliable basis. The calculations of costs for these portable submersible pumps were based upon a daily rental rate, see page 3-508. It would simply be unacceptable, as the DEIS implies, for Water Suppliers to wait until water levels drop to critical levels and then run out to rent some pumps. First, it assumes that there would be an adequate supply of pumps in the size and quantity needed to operate the 55 intakes on the Missouri

River, which is not true. Next, it assumes that one could easily connect the pumps to Missouri River intakes, which is not accurate. Intake operations on the Missouri River are very challenging with varying flows, debris and ice, which make attaching anything to an intake difficult at best, more often dangerous. The DEIS also assumes that all problems could be solved with pumps, which they cannot. It is common for the river channel to migrate away from intakes at periods of low flow, which would make it impossible to reach the water with a pump attached to an intake. Likewise, intakes on the reservoir areas may have to extend pipelines for miles to reach the water.

Correspondence Id: 37 **Comment Id:** 628461 **Coder Name:** jgutierrez

Comment Text: One area of the DEIS that we do have significant concern about is the method the Corps has used to model the impacts of the alternatives on water supply. The economists have used very theoretical and unrealistic assumptions. They have not considered real-world requirements, which are much higher than the minimums mentioned in the Master Manual, due to riverbed degradation, especially in the Kansas City, Leavenworth and St. Joe areas. This flaw was admitted several times in the DEIS, including 3-504 of the DEIS. I'll quote here that "...No Action Alternative does not reflect actual past or future conditions..." The economists use worst case scenarios of the Period of Record and then use hypothetical Master Manual minimum flows to create a baseline. This does not reflect reality. Because of riverbed degradation, the minimum flows mentioned in the Master Manual could not and would not support the water supply intakes in this stretch of the river. As a result, the Corps has assumed that 33 of the 55 water intakes would experience 57 days below operating thresholds, and 21 intakes would experience 14 days below shutdown elevations. These assumptions are totally unacceptable. The Corps should evaluate this approach and model realistic flow requirements to keep water supply intakes in operation at all times.

EC900 Environmental Consequences: Cultural Resources (Substantive)

Correspondence Id: 239 **Comment Id:** 645407 **Coder Name:** jgutierrez

Comment Text: Section & Page Number: 3.9, p. 3-209 - 3-228 Comment: Alternatives that involve increasing flows have the potential to irrevocably harm significant cultural resources (i.e., archaeological sites) at the point of origin or in downstream settings. Increased flows that result in corresponding higher water surface elevations saturate cutbanks and promote conditions for long-term or permanent soil instability that often warrant extensive solutions to correct them. Double Ditch Village State Historic Site, a National Register of Historic Places listed property administered by the State Historical Society of North Dakota, is a current example of an archaeological site that experienced said effects as the result of cutbank saturation from increased flows in 2011. In Lake Sakakawea there is at least one case where ESA habitat corresponded with a significant archaeological site that became exposed during low-pool elevations. Proposed archaeological investigations of that site were rescheduled as a result of nesting concerns. Fluctuating pool elevations dropping to low levels may offer limited or rare windows of opportunity for investigations to cultural resources. If other suitable habitats occur in off-channel settings then the potential conflict between competing management goals (biological vs. cultural) almost certainly would be drastically lessened or negated. Vegetation maintenance and mechanical construction ESH has the least potential to impact cultural resources in the overall scenarios as proposed.

Comment Text: The fluctuations in reservoir elevations contemplated in chapter 3.18 of the Draft EIS will likely be more dramatic than the modeling suggests, resulting in greater impact to cultural resources. If the Corps' overall analysis has any merit, this will especially impact cultural resources at Oahe Reservoir. Nevertheless, the long-term forecast of diminished in-flows to the Missouri

main stem, and long-term drought in the central plains caused by climate change, will cause greater adverse impact to cultural sites than forecast by the Corps in the Draft EIS.

Organization: Great Plains Tribal Water Alliance

Commenter: Reno Red Cloud **Page:** **Paragraph:**

Kept Private: No

Correspondence Id: 232 **Comment Id:** 645442 **Coder Name:** jgutierrez

Comment Text: In the Draft EIS, the Corps mistakenly assumes that the environmental impacts of all alternatives will be equal in light of climate change. It states on page 3-227 - Extremes in climate will likely also magnify periods of wet or dry weather, resulting in longer, more severe droughts, and larger more extensive flooding. Likely impacts to cultural resources would follow from increases to variability of reservoir water surface elevations ... However, it is assumed that the conclusions described would be similar under each alternative. The degree of water elevation fluctuation determines the magnitude of impact to cultural resources at the main stem reservoirs. Each alternative will cause different levels of fluctuation. As acknowledged by the Corps, climate change will intensify both catastrophic rain events and droughts. Consequently, the water level fluctuations will increase exponentially, not arithmetically. The assumption that the impacts of climate change are equal under all alternatives is erroneous.

Organization: Great Plains Tribal Water Alliance

Commenter: Reno Red Cloud **Page:** **Paragraph:**

Correspondence Id: 232 **Comment Id:** 645441 **Coder Name:** jgutierrez

Comment Text: Moreover, the computer simulations used to calculate impacts to cultural resources are based on inaccurate assumptions. According to the Corps, "The analysis assumes that the HEC-RAS and RESSim models reasonably estimate river flows and reservoir levels over the 82-year period of record." (Cultural Resources Environmental Consequences Technical Report, p. 8). The use of the entire 82-year period of record to determine impacts on cultural resources ignores the effects of reservoir construction, and will result in underestimating the actual impacts of water level fluctuations at the reservoirs today. In addition, the assumption fails to consider evidence of diminished stream flows in the tributaries to the Missouri River, and predictive modeling for long-term drought in the central plains. According to Cook et al, "(u)ltimately, the consistency of our results suggests an exceptionally high risk of a multi-decadal megadrought occurring over the Central Plains and Southwest regions ... " (Cook et al, JOURNAL OF AMERICAN Assoc. OF ADVANCEMENT OF SCI. (2015)).

Comment Text: Section & Page Number: 2.9.2.4, p. 2-83 "After the higher release period is completed, the upper three reservoirs have less water than they otherwise would have, and they must recover. During this phase, releases are lower than they otherwise would have been, allowing more water to accumulate in the reservoirs." Comment: It is not clear if the phrase "releases are lower than they otherwise would have been" means that the reservoirs are refilling according to the current Master Manual. If the USACE is operating outside the Master Manual when refilling the reservoirs after the ESH-creating release then that change in operations needs to be described in the EIS. This comment also pertains to Alternative 5 (Section 2.9.2.5, p. 2-86) and Alternative 6 (Section 2.9.2.6, p. 2-88), where similar statements are made.

HEC100 HEC-ResSim Modeling Report: General Comments (Substantive)

Correspondence Id: 167 **Comment Id:** 643848 **Coder Name:** jgutierrez

Comment Text: The USACE includes the following statement at the end of paragraph four on page 3-464 of this section. "...power plant representatives have updated or confirmed the intake elevations during outreach with plants in 2015." Montana-Dakota provided updates to the USACE on intake elevations for Heskett. However, through discussions with the USACE as the EIS was being drafted, we do not believe the updated elevations were physically confirmed with the model inputs. Montana-Dakota recommends USACE confirm the low flow elevations the model is projecting are accurate when compared with the elevations provided by facility owners for low flow event impacts.

Comment Text: 2.3.1.5.4 of the Mainstem Missouri River Reservoir Simulation Report states: ". . . At all projects except Gavins Point, hourly release rates may vary widely as necessary to meet fluctuating power loads. Changes in release rates at Gavins Point are subject to limitations to restrict stage fluctuations downstream. Minimum hourly release restrictions are applicable at Fort Peck and Garrison due to downstream intakes. A uniform peaking release pattern has been established during the summer months at Garrison and Fort Randall for endangered birds nesting along the river below the projects, and may be reinstated at Fort Peck if nesting patterns deem it necessary." Montana-Dakota recommends the USACE provide further review of hourly flows, incorporate discussion on

these potentially impacting low flows and consider the impacts in the evaluations of the alternatives. This review should be considered in addition to the model's attempt at taking the swings into consideration.

Comment Text: Disagreement with Use of 2012 Geometry and Model Predictive Accuracy Based on Heskett Observations

Montana-Dakota would like to emphasize that we do not agree with the use of the Management Plan and EIS using the 2012 channel geometry model to evaluate the impacts of the alternatives if the model has not been proven to be accurate at low flows (those under 15,000 cfs) at Heskett's intake since it appears the only model comparison was done with 2012 observations. The concern extends to USACE's assumptions of the impacts projected from low releases using this modeling. It appears that the USACE model associated with this project uses historical flows and the 2012 river geometry survey to predict the impact to the Heskett intake and whether the station would be able to withdraw from the river (based on the intake elevations and modeled results). It appears that the model does not take into account channel changes since the survey was conducted, as well as Oahe Lake effects within the river reach near Heskett and channel siltation. In our experience, the channel changes yearly as winter ice freezes over the river and re-directs flows differently each year underneath the ice until ice breakup occurs. We are also concerned that actual elevations at Heskett's intake were not confirmed at the time of the 2012 survey. Due to the changes that occur yearly in the stretch between Bismarck and Garrison Dam, we feel the 2012 survey is not accurately representing the flow impacts near Heskett. Montana-Dakota requests that the USACE confirm whether the model corresponds to flow and elevations outside of the 2012 survey timeframe and make model adjustments accordingly to demonstrate accurate predictions. Additionally, we recommend the USACE consider evaluating this for all affected water users. Montana-Dakota recommends the USACE also review the model accuracy to consider the consequences of multiple stations along the Missouri River being affected by low releases. The effect of the loss of generation from multiple facilities in a single period is much more significant than the loss of generation from one facility. Loss of generation from multiple regional or local generation resources may have the potential for a larger impact to transmission grid reliability. This subject requires more than the limited amount of discussion found on page 3-475 of the MRRMP-EIS. Further, Montana-Dakota believes that a reliability impact from implementing the alternatives is beyond what is considered as a loss of revenue if multiple generation resources would be offline, and we recommend USACE include reliability consideration in the impact analysis of the alternatives.

HH1000 Hydrology and Hydraulics Modeling (Substantive)

Correspondence Id: 98 **Comment Id:** 633687 **Coder Name:** jgutierrez

Comment Text: In examining each of the DEIS alternatives, a concern common to each is the lack of hydrologic and economic modeling. We cannot even begin to understand the impacts to flood control and interior drainage because the DEIS only completed modeling for four levee sites in the entire floodplain. This is a severe flaw and we call on the Corps to complete hydrologic modeling and peer reviewed comprehensive economic impact studies for the entire floodplain before any flow management action is implemented. Based upon the possible pallid sturgeon spawning cue release implementation in years 9-10 under the Preferred Alternative, we believe the Corps has adequate time to fully develop this essential modeling so our members can have a much clearer picture of how management plan actions may affect them.

Correspondence Id: 228 **Comment Id:** 645523 **Coder Name:** jgutierrez

Comment Text: 2. The DEIS is incomplete without the hydrologic modeling for impacts to interior drainage. Interior drainage impacts are downplayed and not even mentioned through much of the economic analysis. It is such an afterthought, that the agencies have not updated the software to make it compatible with today's computer operating system. Therefore, analysis of the floodplain was not performed. Instead of updating the software so that credible analysis could be performed for the entire floodplain, four representative sites were selected and a cursory impact study was performed. Again, we point to the following statement made in the DEIS: Extrapolation from the four sites to other levee areas was not feasible since the hydraulics, hydrology, and drainage varies between sites. Translation of damage duration relationships between sites was not attempted and would require additional evaluation to provide a reasonable methodology and verify results. This methodology is entirely unacceptable. 3. The lack of modeling for interior drainage impacts is a severe flaw in the DEIS and is, frankly, inexplicable. The most pervasive impact-imposed interior drainage was not thought to be enough of a priority to create modeling and verify impacts. Interior drainage has a more frequent, and depending on the duration and severity of flooding, can have a greater economic impact than flooding. Therefore, the DEIS stated economic impacts are a fraction of total economic impacts because the flow management actions on interior drainage are missing from the analysis. This omission is entirely unacceptable and it makes the DEIS incomplete and renders any claim of accurately predicted impacts of all 6 alternatives invalid.

Organization: Coalition to Protect the Missouri River

Commenter: Dan Engemann **Page:** **Paragraph:**

Correspondence Id: 228 **Comment Id:** 645467 **Coder Name:** jgutierrez

Comment Text: Upon our review of the DEIS, a top-tier concern is the lack of hydrologic and economic modeling throughout the document that minimizes the potential for negative impacts that could be caused by implementation of any of the alternatives. For example, one of the most egregious errors in this document is the incomplete nature of the Corps analysis of impacts to interior drainage by only sampling four levee sites in the entire lower Missouri River basin. Through this limited approach, we cannot have any degree of confidence in the impacts of the DEIS alternatives. The CPR cannot fully comment on the impacts until such modeling is completed. We are troubled by the lack of hydrologic modeling of the impacts to stakeholders if a one-time spawning cue release were to be implemented. The DEIS states: The one-time spawning cue test (Level 2) release that may be implemented under Alternatives 3, 4, and 5 was not included in hydrologic modeling for these alternatives because of the uncertainty of the hydrologic conditions that would be present if implemented. The CPR wants to be abundantly clear in our position - hydrologic modeling and peer reviewed comprehensive economic impact studies must be completed before any flow management action is implemented. Under Alternative 3's possible implementation of a one-time spawning cue release 9-10 years in the future, we feel strongly that adequate time exists to complete a full analysis of the impacts to stakeholders. If complete hydrologic and economic modeling for the

entire floodplain is not finished before implementation, the CPR will take action to prevent adverse impacts from being forced upon stakeholders.

Organization: Coalition to Protect the Missouri River

Commenter: Dan Engemann **Page:** **Paragraph:**

Correspondence Id: 238 **Comment Id:** 645331 **Coder Name:** jgutierrez

Comment Text: 3) Flow modeling for the alternatives is incomplete and not accurate The No Action Alternative is not accurate and does not serve as an appropriate baseline: The basis for all of the Alternatives in the EIS rests on the comparison to the No Action Alternative, or the existing conditions in the Missouri River system. As utilized in the EIS, the No Action alternative is a simulation of how the system is currently operated, including current MRRP actions, "but does not and cannot take into account the numerous minor adjustments to basic rules that the Corps actually makes to reasonably address critical short-term situations (e.g., increase releases for water supply, reducing releases for ice jams, etc.)." Therefore, modeling results of the No Action alternative do not reflect actual past or future conditions but serve as a reasonable basis or "baseline" for comparing the impacts of the action alternatives on resources. This approach sets false expectations for future management scenarios and inflates the value of the baseline alternative to the pallid sturgeon. To serve as an accurate representation of the No Action alternative, the Corps should consider modeling the alternative based on actual historic conditions and operations of the reservoirs. Doing so will encompass the actual variability in flows and allow for a more realistic implementation, set of alternatives, and adaptive management plan. Modeling Spawning Cue Release for Pallid Sturgeon: For the purposes of modeling the No Action alternative, the Corps assumed implementation of the plenary spring pulse as described in the Master Manual would occur. This action would include a March and May spring pulse from Gavins Point Dam. However, the EIS states that a one-time spawning cue was not incorporated in hydrologic models. The Corps stated in the EIS that they are unable to model this discrete release. Because the Corps will need to understand the impacts of releases, even short ones, on the operations and downstream water availability, this calls to question the ability to implement this component of the alternative. If the Corps is unable to model this release based on their existing modeling software, they should either explore other resources for modeling or develop a set of decision-criteria so that the public can have confidence in the implementation of this flow release.

Comment Text: Another example of the problems with the over reliance on averages and the use of the 82-year period-of-record in the models are the years 2011 and 2012. In 2011, the Missouri River experienced one of the worst flood events in its history, and this event was followed by a severe drought in 2012. Both the flood of 2011 and the severe drought of 2012 caused massive damages to the navigation and agriculture communities, with impacts still seen. There was nothing average about 2011 and 2012, but the use of the 82-year period-of record minimizes the massive damages.

Comment Text: One of the major deficiencies in the economic modeling is it relies too heavily on averages when more detailed information is available and already documented. The ISETR panel stated that the documentation for these models is in need of improvement. The economic impacts of the proposed alternatives on human considerations are measured over an 82-year period-of-record. Likewise, measurements of impacts to resources were based on an 82-year hydrologic period-of-record. The 82-year period-of-record does not properly represent the true impacts of the proposed alternatives on the various stakeholders because it skews the effects of major high- and low-water events, such as the great floods of 1993 and 2011, as well as the severe droughts of 1988, 1989 and 2012. Under this 82-year period-of-record, the negative impacts of these alternatives are significantly understated. This is particularly the case regarding the navigation industry, which was almost decimated by the drought of the late 1980s.

Comment Text: "Utilizing the 82-year period-of-record is flawed because it includes years where the federal government mandated artificial regulatory actions that greatly diminished the presence of navigation on the Missouri River. This, in turn, results in the DEIS significantly understating the benefits of navigation on the Missouri River. As stated previously, the low summer flows on the Missouri River in the early 2000s caused navigation to virtually disappear. Several towing companies went out of business during this time due to the lack of consistent reliable flows on the Missouri River. A few years later, the Corps implemented a large spring rise under the auspices of a spawning cue for the pallid sturgeon. This second artificial federal government mandate further discouraged navigation on the river due to flow reliability concerns. In fact, navigation on the Missouri River did not begin to recover until recent years when the Corps stopped these flow mandates. Yet, despite these artificial government mandates that negatively impacted navigation during these years, the DEIS still includes these years in the period-of record for the modeling. These years should be excluded from the modeling, otherwise the benefits of navigation are substantially understated in the DEIS.

Comment Text: Heskett Minimum Flow Compared to Model Flow Prediction Montana-Dakota is unsure whether the USACE's model projection of cfs river flow at Heskett's intake represents the flow level at which the unit would expect to encounter a shutdown. Based on previous discussions with the USACE's consultant, Montana-Dakota was informed that the model indicated Heskett would not shut down until a river flow of 5,000 cfs. We told the USACE's consultant that the 5,000 cfs low flow was inaccurate. We are unaware if any adjustments were made to the model. Based on recent observations, it is Montana-Dakota's belief that flows as low as 10,000 cfs would create a shutdown condition. In the past, flows as low as 12,000 cfs have created a shutdown

condition. Montana-Dakota would appreciate the USACE taking a close evaluation of the model in Heskett's reach and review actual elevation measurements to ensure the model is accurately predicting low flows for facilities. If shutdown events occur with higher flows than currently described by the model, the impacts should be reflected in the alternatives.

Comment Text: In examining each of the alternatives, a concern common to each is the lack of hydrologic and economic modeling. We cannot even begin to understand the impacts to flood control and interior drainage because the DEIS only completed modeling for four levee sites in the entire floodplain. This is a flaw that cannot be overlooked and we urge the Corps to complete hydrologic modeling and peer reviewed comprehensive economic impact studies for the entire floodplain before any flow management action is implemented. Once this modeling is complete, it is then important that the models should only be considered one tool in the decision-making tool box. Though thorough modeling is an important part of the process, the outcome of a model should not exclusively determine a decision. It should only be used as part of the equation.

Comment Text: Failure to recognize the reality of current operations - The DEIS analysis of the baseline in Alternative 1 discussed in several sections, including section 3.18.2.4, is based upon a very theoretical operation of the river that does not recognize the real world flows required by the Water Management Center to keep intakes in operations. The Corps only modeled the 82-year period of record using very theoretical operations that the Master Manual might allow. Page 3-507 of the DEIS states, &the impacts modeled do not account for the ability of water management to adapt to changing conditions on the system to serve authorized purposes, such as water supply.

Comment Text: The Fort Peck reach supports 29 of Montana's 56 native species, including the pallid sturgeon and six Species of Special Concern, including the shortnose gar, sicklefin and sturgeon chub, sauger, blue sucker, and paddlefish. To support spawning, warm water flows of 20,000 to 30,000 cfs with water temperatures of 64° F were meant to be sent over the spillway between the middle of May and the end of June to stimulate spawning response. However, these releases have not occurred because the drought has so severely limited water levels in the Fort Peck Reservoir. From 2001-2009, the U.S. FWS and USGS monitored water temperature above and below the dam and in the Yellowstone to determine optimal conditions for the pallid sturgeon. These studies found that water temperature upstream of Fort Peck was nearly 12° warmer upstream than downstream (67° vs. 54° F) and maximum temperatures were 19° warmer above Fort Peck (79° vs. 60° F). Temperature impacts spread as much as 180 miles downstream, nearly the entire reach before the Yellowstone confluence. Without releases from the dam, temperatures reached target values twice in 2005 and 2007, driven by warm water from the Milk River and the Yellowstone River. When the Milk River contributed to warm water flows in the Missouri River, a significant shift in sturgeon populations occurred, increasing from less than 5% to 30% of the population above Lake Sakakawea. In addition to spawning and migration cues, higher temperatures contribute to faster growth rates.

Comment Text: The AMP (AMP 2-page 455) states that "some priorities for water use are mutually contradictory, the need to find a reasonable balance among HC interests has therefore always been central to the operation of the System." The League has concerns that the priorities are highly out of balance now. We feel navigation is heavily favored, even though there is little or no use of the river

for commercial traffic outside of a 10 mile segment near Kansas City. At times, the reservoirs appear to be managed only for benefit of a few in the lower basin. Continued drawdowns, coupled with extended drought conditions leave boat ramps unusable. For example, in 2006, full service flows were provided for navigation even with little or no commercial navigation traffic. The reservoirs then hit record low levels in 2007. This demonstrates that a more balance approach is needed.

Comment Text: The League believes recovery can and needs to happen on the lower river. The AMP (AMP 2-page 419) indicates that pallids spawned successfully in 2014 around Sioux City, above the Platte River. This is encouraging. We wonder how much more spawning we would see in that area if navigation was de-authorized in the upper end of what is now a rarely used navigation channel, so that recovery and restoration efforts could flourish. We ask for this to be considered in the final EIS.

Comment Text: Many Tribes remain impacted by Pick-Sloan authorized projects on tributaries to the Missouri River. The Committee on Indian Affairs reported Pick-Sloan's impacts on the Oglala Sioux Tribe, as follows - The Angostura Unit is located about twenty miles upstream from the Pine Ridge Reservation. Notwithstanding the economic benefits provided by the Angostura Unit to the people of southwestern South Dakota, the operation of the unit provides no economic benefit to the Oglala Sioux Tribe, which experiences extremely high rates of unemployment and poverty. Additionally, the operation of the Angostura Unit has had an adverse impact on water quality and fish and wildlife resources within the Oglala Sioux Tribe's reservation. (S. Rep. 110-506 (2009), p. 2). The Pick-Sloan program has resulted in diminished abundance of cottonwoods in the riparian environments of the Great Plains Water Alliance Tribes. Nearly one-half million acres of on-Reservation bottomlands were destroyed along the Missouri main stem. The capture of sediment at tributary projects such as Angostura, Whitney Dam and Belle Fouche has altered the depths of river channels and impacted groundwater levels needed for cottonwood regeneration. Riparian species such as cottonwood and willow have important ceremonial uses for the Lakota and Dakota, but are less abundant due to Pick-Sloan. These impacts matter, and should be fully disclosed in the Draft EIS. The construction and operation of the Missouri River main stem dams by the Corps of Engineers has

an extremely significant and on-going impact on the water supplies, economies, culturally-significant and medicinal plants, fish and wildlife and historic properties of the Tribes of the Great Plains Water Alliance.

Comment Text: Removal of commercial navigation north of St. Joseph, MO - The Corps refuses to recognize that the use of the river for barge traffic in the IA-NE reach is almost non-existent. There isnt a business model anywhere which would continue to expend materials and money in large quantities for an economic plan in which so little return is achieved. Adjustments to the Master Manual should be made. The huge cost to maintain the navigation channel for so little cargo in this reach is never mentioned in this DEIS. It is a myth that barges must be maintained for agriculture. While there is some grain hauled via barges in this reach of the river, trains haul a considerable amount and can take it faster to market terminals. There are unit trains in the western Great Plains which carry grain across the Rockies straight to west coast terminals. The old argument that barge traffic has a smaller environmental footprint than rail or truck sounds nice, but really doesnt excuse the resultant more heavy impact to the rivers habitat as a consequence of maintaining the navigation channel. The cost to the rivers environmental condition to maintain the navigation channel for so few barges is omitted from any of these discussions and is an unfair favoritism to a small fraction of society. It is the destructiveness of maintaining one use at the expense of another.

Comment Text: South Dakota supports the use of the ProACT structured decision-making process to identify major human considerations and effects of various management actions on specific stakeholder groups. The ProACT process, and its use of proxy metrics, was helpful in illustrating trends in management action impacts on stakeholder groups. However, the amount of information initially considered in the ProACT exercise and the need to synthesize that information to something manageable certainly resulted in some potential, specific impacts to stakeholder groups and authorized purposes being lost in the analysis. Therefore, we have included the following information that highlights how specific management actions included in the alternatives presented for consideration have impacts for the State of South Dakota and our stakeholders, which are not adequately identified in the draft EIS.

Comment Text: Outside of concerns for the listed species, the Missouri River reservoir system was created by the Corps of Engineers, and it should be their responsibility to maintain the system and mitigate any negative impacts of its creation. Flood control, navigation, and other benefits of the mainstem reservoir system come at the cost of increased sedimentation, flow constraints, and the likelihood of flooding in the riverine section from Ft. Randall Dam to Lewis and Clark. These issues need to be addressed. If the flow constraint from Ft. Randall Dam to Lewis and Clark is not remedied, it will effectively negate using flow as a management tool or result in flooding of South Dakota residents. Waiting 9-to-10 years to see if increased flows are needed for species recovery and to begin working on increasing the channel capacity from Ft. Randall Dam to Lewis and Clark Lake is not acceptable. This delays addressing the sediment issue that already exists and which needs to be remedied.

Comment Text: As stated in Section 1.1.5 of the MRRMP and EIS, congress authorized the Missouri River Bank Stabilization and Navigation Project (BSNP) Fish and Wildlife Mitigation Project in the 1986 Water Resources Development Act (WRDA), Section 610 (A). WRDA 1999 Section 334 expanded the total number of acres to be mitigated to 166,750. To date, only about 66,000 acres have been developed. While habitat development and land management on Missouri River Recovery Program lands is a management action listed under all alternatives, emphasis on acquisition and management of lands, to satisfy the mitigation responsibilities associated with the BSNP and to aid in species recovery, should be increased. Strategic acquisition of additional acres, from willing sellers, or establishment of easements to create habitat, should be pursued to reduce flow constraints and to serve as suitable locations for pallid sturgeon spawning habitat and IRCs.

Comment Text: At many times I've been critical of the 2000 and 2003 Missouri River Biological Opinions (BiOps), the MRRP and its past actions to reduce jeopardy to the listed species. In my opinion the DEIS and DSAMP represent a monumental step forward towards performance based management planning for the Missouri River and the U.S. Army Corps of Engineers (Corps) responsibility to comply with the Endangered Species Act while . Specifically the DEIS and SAMP thoroughly address each of the seven actions the ISAP and MRRIC recommended to the Corps and U.S. Fish and Wildlife Service (FWS) in August 2012. Most importantly, the SAMP provides a much improved road map to designing, implementing and evaluating consequences of future management actions and identifies mechanisms of accountability for implementing a science based program to reduce jeopardy to the three listed species while addressing relevant human considerations (HCs). Such a robust adaptive management process has heretofore been lacking in MRRP documents and actions. Whichever alternative the Corps selects, the challenge will be to effectively implement it under an anticipated restrictive future fiscal environment. The MRRMP's success at achieving objectives for the three listed species depends on effective implementation of the SAMP to reduce uncertainties through the Integrated Science Program (ISP) . Consequently, most of my concerns relate to the allocation of resources to implement management actions and the perceived ability of the ISP to conduct effective research, monitoring and evaluation so that adaptive management can be operationally implemented to

reduce jeopardy. Fundamentally, the authenticity of proposed management actions in the DEIS can transparently substantiated by the resources allocated to accomplish them.

Comment Text: Finally, the 8th Circuit Court of Appeals in their 2005 decision clearly stated, quote, if due to extreme conditions the Corps is faced in the future with the unhappy choice of abandoning flood control and navigation on the one hand, and recreation, Fish & Wildlife on the other, that priorities established in the Flood Control Act would forbid the abandonment of flood control or navigation. In the same document, the Court reiterated its earlier opinion that the Flood Control Act has been interpreted to hold flood control and navigation dominate and recreation and Fish & Wildlife secondary. The Northwestern Division would do well to follow the advice of the federal court. The Corps of Engineers has a moral obligation, a duty and a mission outlined by Congress to provide flood control for the citizens of our country. The Northwestern Division should not turn its back on Congress and should find a way to protect these species while following through with their flood control mission. This is a charge of Congress and it's the desire of the people. However, this is not what the Draft Environmental Impact Statement sets out to do. There must be a better way, and the Division should continue to work to find it without implementing the alternatives in the Draft Environment Impact Statement.

Comment Text: Third, in 2010, the Sierra Club, national Water Sentinels, Missouri Coalition for the Environment, Great Rivers Environmental Law petitioned Fish and Wildlife Service for pallid sturgeon critical habitat designation on the Missouri River. This request was deferred by FWS based on a lack of resources and insufficient conservation priority number. I believe at this time it is

time for the Fish and Wildlife Service and the Corps to reconsider and to designate a critical habitat and to incorporate it into the adaptive management plan.

Comment Text: It has come to our attention that the U.S. Army Corps of Engineers, in cooperation with the U.S. Fish and Wildlife Service have developed the Missouri River Recovery Management Plan and Environmental Impact Statement ("the Plan"). It is imperative the United States Corps of Engineers reconsider the impact of the proposed plan and amend it so as to make real economic growth possible by having a minimum navigable draft level of the Missouri River in the vicinity of Callaway and Cole Counties of nine feet for at least eight months, preferably nine months, of each year. This is very important. It is our understanding this plan would change the water levels and flows of the Missouri River. The Missouri River has been a staple in the past and more important than ever in moving large quantities of corn, soybeans, agriculture fertilizer, rock and gravel, sand, cement, fabricated steel, and large industrial equipment and machinery. Military equipment from National Guard facilities throughout the State of Missouri could also be moved by barge. This mode of transportation is by far the most cost effective and efficient method of moving these products long distances. Relationships have been developed with both foreign and domestic business alliances. The newly widened Panama Canal offers us business opportunities we have never been able to pursue until now. Customers are wanting to buy products from our region of the country. We must be able to ship these large quantities of products and materials cost effectively and in a timely manner. Barge transportation is the only viable solution to this new demand. Highly regarded captains, tugs, and barge providers are already in place to ensure these very sizeable business transactions are completed on time and with the highest degree of professionalism. The Corps indicated in a recent meeting in Kansas City, they were ready and willing to assist in any way to make this a reality. Your

commitment to making increased economic growth of barge transportation the Missouri River a priority is very encouraging. The below signed entities are in agreement in our request that the Corps of Engineers continue to consider the importance of the Missouri River as a transportation opportunity by ensuring the United States Corps of Engineers reconsider the impact of the proposed Plan and amend it by having a minimum navigable draft level of the Missouri River in the vicinity of Callaway and Cole Counties of nine feet for at least eight months, and preferably nine months, of each year.

Comment Text: I believe there are multiple beneficiaries from continued development of the river system. The resource of the river is obviously benefited, but also the economic impact on the surrounding communities. The urbanization of our country will cause smaller towns to get smaller and the natural resources around these communities are often their only hope.

Comment Text: In 2009, the corps bought 190 acres from the Papio Missouri River NRD that adjoins our farm ground to the south called Little Sioux Bend. In August of 2015 a double looped pallid sturgeon chute was constructed. We watched the process and all the sand was dredged out into the river. We now have a higher water table which is up and down the river where these chutes were constructed. Along with this process the rock dike was notched and there is a great deal of bank erosion going on. This notching has been done by the corps up and down the river. The aerial view tells the whole story. Our farm ground is very close to this area. The corps need to come back ASAP to fill in the dike with rock. We lost 30 acres to the north of this area to the 2011 flood. This 30 acres is covered with 15 feet of sand, covered with trees, and weeds. This piece of ground will never be farmed again. We are still having to pay taxes on this wasteland. The corps can purchase ground and it is tax exempt. This is so wrong!

Comment Text: WaterOne supports the responsible management of the Missouri River resources and the maintenance of the eight congressionally authorized purposes of the river. Congress mandated the Corps to protect the lives and safety of the residents of the Missouri River Basin, and primary in that mandate is the responsibility to safeguard the Water Supply for stakeholders like WaterOne. Interrupting water supply for even one day would have catastrophic impacts on people who live and work in the Missouri River basin. The 425,000 residents served by WaterOne rely on the Missouri River for their daily water needs for domestic and sanitary use as well as for fire protection. WaterOne serves 13,000 commercial accounts (businesses). While these commercial customers account for around 10 percent of our 145,000 customer accounts, they represent 30% of WaterOnes total demands. These commercial accounts also represent the economic engine of the State of Kansas. Interruptions of water supply can be troublesome to residential customers but can have catastrophic impacts to health care facilities and major economic impacts to education, businesses and industry. A 2017 report by the Value of Water Campaign entitled The Economic Benefits of Investing in Water Infrastructure documents that water service disruptions put \$43.5 billion in daily economic activity at risk. It is imperative that the Corp honor its mission to protect the Water Supply of the Missouri River as its foremost priority.

Comment Text: It is a travesty that millions of dollars have been spent on mechanically-constructed but ephemeral ESH, based on flawed BiOps from USFWS in 2000 and 2003. These BiOps were written essentially without any scientific data, but nevertheless USACE charged ahead with ESH and chute construction. Both have both turned out to be ineffective in contributing to the long-term populations of the three listed species, especially in the case of the Piping Plover and Least Ter (Figure 3-29, Missouri River Recovery Management Plan and Environmental Impact Statement (MRRMP-EIS), Volume 2; Figure 3, Duberstein 2011), and undetectably so in the case of the Pallid Sturgeon.

Comment Text: While the proposed AMP is a rational approach to this uncertainty, there is one area where it needs to be strengthened. Theories purporting to aid in species recovery inevitably gain a constituency. These constituents passionately argue for the veracity of their theory and the need for research funding to test the theory. When faced with evidence contradicting their theory, these advocates then argue for slight adjustments to the theory followed by a request for additional research to support the newly-revised theory. The result can be a never-ending cycle of adjustment and additional research for a theory that should have been discarded but for the constituency supporting it.

Comment Text: Further, mitigation efforts seem to be solely focused on listed species while the USACE's responsibility within the Mitigation Project was to be dedicated to all native species. Not only could mitigation efforts be used for habitat rehabilitation for fish and wildlife, but would provide benefits considering flood risk management and nutrient reductions entering the Missouri River (Sparks 1995). With multiple flood events occurring on the Missouri River in recent years, obtaining mitigation lands in the floodplain will provide benefits to landowners and tax payers by reducing the extensive damage and costs caused by these recurring flood events. Having mitigation acres within the floodplain will also increase the hydraulic capacity, thus reducing the magnitude of floods, and reducing the amount of nutrients that run off the landscape and into our river systems; all while benefiting fish and wildlife at the same time (Sparks 1995).

Comment Text: The ISAP, established by the Missouri River Recovery Implementation Committee (MRRIC) to develop scientifically sound adaptive management actions, issued a report in 2011 that recommended development of an overarching adaptive management plan that would implement a combination of flow management actions and mechanical habitat construction, which are the primary proposed actions in all alternatives. ISAPs recommended AM Plan recognizes the urgency of action for the pallid sturgeon, as the number of natural born mating specimens is dwindling, and allows for anticipated implementation actions, but these actions are based on the effects analysis, which incorporates new knowledge learned about the species since the BiOp was last amended in 2003. For example, as highlighted in ISAPs 2011 report, the spring pulse spawning cue management action as implemented in Alternative 1 by the 2000 BiOp was not effective in achieving pallid sturgeon objectives. The proposed AM Plan would take this result into account and tailor adaptive management responses for the pallid sturgeon.

Comment Text: The Adaptive Management Process (AMP) proposed in the DEIS is a reasonable component of the recovery plan, especially for the pallid sturgeon, largely because so little scientific data is currently available. For example, recent research (Anthony Civiello, USACE, The Influence of Shallow-Water Habitat on Age-0 Shovelnose Sturgeon Diet and Condition) calls into question the efficacy of constructing interception and rearing complexes (IRC's). However, IRC construction is a significant component of the recovery plan for the pallid sturgeon contained in the DEIS. The AMP will help to reconcile new or conflicting data about different theories for recovery of the pallid.

Comment Text: All interests will, can, and do fit together for the benefit of this project, because what has been asked of us to regenerate for habitat , once was, but destroyed by poor decisions and mismanagement. The reason I so firmly believe this, is God made it possible for myself, family, friends, and those who lived beside the Missouri River and were on it from 1970's-1990's, personally witnessed and enjoyed a "Missouri River Gone By". The "Missouri River Gone By" was the " Missouri River Dreamed of Now" . This river that I speak of, was a slower moving, with dikes that slowed the water and held sandbars for birds and places to pull a boat upon and picnic with family, families fished, swim, tubed and even water-skied, and floated on tubes, there was not near the flooding and the damage that came from such an event, navigation was routine and the dredging companies kept the main channel deeper on the river also. This river that I tell you about is truly what is being ask of the US Fish and Wildlife to recreate, but they can't without going back and putting back dikes that slowed the waters and help create the sandbars, and keep the sediment from being put into the channel, and doing practices that contribute to the river not being able to carry the amount of water it did then. (I believe that some chutes would contribute to the enhancement of the river and habitat, but the practice or experiment that was done at the start in

cutting dikes everywhere, notching banks and destabilizing banks, and making levees vulnerable and in floods since then left large damage to the levees and weaken to this day. Flooding comes at lessor flood stages now than they did and more damage. Instead of this mentally of "a kid in a sand pile with a crowbar" and if the bank notching and cutting of the dikes had been organized in portions of the river and not everywhere, until visible results could be accounted for and adjustments made for the betterment of restoration projects we would not have inadequate progress and rebuilding to be done.

Comment Text: According to Table A.3.1 (Summary of Features Comprising the MRRP-EIS Alternatives Carried Forward for Detailed Consideration), Alternatives 1 and 2 do not include Level 1 (research without changes to the system) or Level 2 (In-river testing, with local implementation) studies. Adaptive Management with monitoring was described as the fourth action to be taken in the 2000/2003 Biological Opinion. Thus, if implemented, Alternatives 1 and 2 appear to have some component of adaptive

management. The EIS describes adaptive management under Alternatives 1 and 2 would continue as implemented since 2009, and for aquatic species would include shallow water habitat creation (page ix).

Comment Text: Science-based planning can promote agriculture, ensure sustainable economic development, and enhance fish and wildlife benefits. The AM Plan and EIS together should continue to balance all the eight authorized purposes of the Missouri River to maximize benefits for Missourians and the nation. Currently these documents focus on USACE responsibility under the ESA, although the proposed federal actions would impact wildlife managed by state fish and wildlife agencies.

Comment Text: The world saw the impacts from Missouri River flows during the drought of 2012-2013. Once Missouri River navigation flows were decreased after December 1, 2012, the reliability of Mississippi River flows was severely threatened. Due to the critical impacts that Missouri River management flows have on the Mississippi River, any future flow changes would negatively impact the commerce on the nations marine superhighway and the nations economy.

Comment Text: WCI has been an alternate representative for agriculture stakeholders on the Missouri River Recovery Implementation Committee (MRRIC) since its inception in autumn 2008. Authorized by Congress in Section 5018 of the 2007 Water Resources Development Act, MRRIC is comprised of nearly 70 representatives of tribes, stakeholder groups, states, and federal agencies. The Committee is charged with providing guidance to federal agencies on the existing Missouri River recovery plan, including priorities for recovery work and implementing changes based on the results of adaptive management, and developing recommendations that recognize the social, economic and cultural interests of stakeholders, mitigate the impacts on those interests and advance the multiple uses of the river.

Comment Text: Toward this end, the Sierra Club Missouri River Grassroots Network calls upon the Fish & Wildlife Service, the Corps and the scientific community actively working these endangered species problems to consider- - within this DEIS, and within an Adaptive Management context- - that the pallid sturgeon's full extant range is critical habitat for it's continued survival and persistence. Such a designation would give pallid sturgeon additional protections prohibiting the destruction of its habitat, without consultation and permitting. This call is for renewed attention and resources in response to a petition submitted to the US Fish & Wildlife Service by the Missouri Coalition for the Environment, the Sierra Club National Water Sentinels Clean Water Campaign, and Great Rivers Environmental Law Center in 2010. In 2010, the Sierra Club (National Water Sentinels), the Missouri Coalition for the Environment and Great Rivers Environmental Law petitioned FWS for Pallid Sturgeon Critical Habitat designation on the Missouri River. The request was deferred by FWS based on a lack of resources and insufficient conservation priority. It is time for the Fish & Wildlife Service to reconsider and to designate Critical Habitat and the Corps should incorporate critical habitat into the Adaptive Management Plan. At present, critical habitat is described and considered only for the Terns and Plovers in Appendix section G.3

Comment Text: In general, examination of extreme drought management (over a period of multiple drought years) is not well discussed in the DEIS; neither are the implications of upstream diversions as an interagency result, upon the existing POR hydrograph or operations and management. If multiple, foreseeable and planned diversions (Garrison Diversion, and/or two of the eight BoR "Secure Water" plans for diverting Mo River water to the Colorado River, and/or some other diversion), were to eventuate in 10-30% reductions in Run of River flows, that eventuality is unstudied in this DEIS. The plans are there, why not study them?

Comment Text: TNC strongly supports the process and involvement that could be termed non-standard for USACE in EIS efforts. TNC believes the high stakeholder involvement through MRRIC and use of an Effects Analysis (EA) as the best available science and the basis of the Adaptive Management Plan (AMP) coupled with the Independent Science Advisory Panel's (ISAP) and Independent Social Economic Technical Review Panel's (ISETR) independent review of the science applied is a model of what a federal decision making process at this scale should include. TNC encourages USACE to apply this model to its other large scale water resource planning efforts nationwide. TNC is very supportive of the contents and structure of the AMP and agrees with the tiered approach to some management actions given some of the current uncertainty surrounding their effectiveness. This draft MRRMP-EIS marks a significant advancement in USACE Missouri River Recovery Program and U.S. Fish and Wildlife Service endangered species planning for the Missouri River. However, TNC does have an overarching concern and some more specific concerns with the draft MRRMP-EIS.

Comment Text: The USA CE, in concert with the State, must develop guidance on how mitigation in the connected Missouri River Yellowstone River ecosystem will avoid jeopardy to Pallid Sturgeon as well as mitigate for impacts to other native fish and wildlife species. This should be included in the alternative analysis of the MRRMP-EIS prior to its finalization. Mitigation efforts could easily be established as part of the SAMP and their inclusion could be justified as Level 3 and Level 4 studies in answering Big Question 2 (Flow Naturalization and Productivity), Big Question 3 (Temperature Manipulations at Fort Peck), and Big Question 5 (Passage, Drift and Recruitment). Doing so would provide consistency with the goal of the Missouri River Recovery Program to create a sustainable ecosystem supporting thriving populations of native species while addressing major impacts of current and past river uses.

Comment Text: The DEIS admits "a supplemental NEPA process may be necessary prior to the end of the 15-year period." Yet, it then fails to clarify the kind of action which would trigger this requirement, such as going beyond the dictates of the Master Manual. Instead, the DEIS permits the Corps to take actions that have not been fully vetted or even proposed, without a supplemental EIS and

input from stakeholders. Though scientific monitoring requires a flexible approach, the present AM plan goes well beyond reasonable flexibility and that it fails to adhere to legislative requirements clearly established under NEPA and reaffirmed by the courts. Under the guise of scientifically necessary, the DEIS is suggesting the Corps have unfettered ability to go beyond reasonable limitations of the ROD or Master Manual without the accountability of a supplemental EIS.

Comment Text: Section 4.0 Adaptive Management Plan General Analysis: 1. By definition and design, adaptive management (AM) means the management actions are not yet identified. We can only speculate on the direction of impacts because we only know the direction of management actions. It is impossible to provide the appropriate quality and scope of comments on management actions when not even the Corps or the FWS knows what actions they will take. AM plan decisions made outside of the ROD and Master Manual must go through full NEPA review and a separate EIS and must include independent peer review of the science and be coupled with full public review and comment before finalized. 2. The Corps should communicate what actions they believe to be implementable under AM. If stakeholders are to participate in a meaningful way, no decisions should be made in a vacuum or come as a surprise. 3. The Corps should commit to the use of two independent panels in AM plan independent review. We believe socio-economic impact review and analysis to be a key part of AM and it should continue to be utilized. As weve pointed out, the DEIS modeling and assessment of human impacts is woefully inadequate, highlighting the important need for review by both panels.

Comment Text: Section & Page Number: 2.4.3, p. 2-12 The third paragraph of the section briefly describes the model that was used to simulate erosion and deposition of ESH. The paragraph references a report written by Fischenich et al. (2014) that has additional information regarding how changes in ESH was modeled. The "References" section cites this report as the following: Fischenich, J.C., R. McComas, D. Meier, J. Tripe, D. Pridal, P. Boyd, S. Gibson, J. Hickey, T. Econopouly, and L. Strong. 2014. Habitat Analyses for the Missouri River Effects Analysis - Geomorphic Team Integrative Report. Comment: The Effects Analysis reports are the basis for the AMP and the alternatives evaluated in the EIS. The Fischenich et al. report is a crucial document underpinning the geomorphic analysis. This report was not made available to the public along with the other Effects Analysis reports that were released with the MRRMP-EIS. It was only disclosed (in an incomplete version) after February 16, which was halfway through the 120-day comment period. This compromised our ability to conduct a full and rigorous review of the material. Not releasing this report at the beginning of the comment period is the opposite of being open and transparent, and is at odds with the spirit and requirements of NEPA and the Administrative Procedures Act that the agency provide a meaningful opportunity for review and comment on the technical bases being relied upon by the agency. Additional comments are included in the section of this document dedicated to this report.

Comment Text: Upon closer examination of the case law, it is clear the courts have a history of reiterating the need to initiate the NEPA process for substantial changes. In *Operation of the Mo River Sys. Litig., Mo. v. U.S. Army Corps of Engrs*, the Eighth Circuit clarified substantial changes are those that are not qualitatively within the spectrum of alternatives that were discussed in a prior EIS. The DEIS is presently a perfect example of permitting substantial changes without fully satisfying NEPA requirements. A mere mention of an alternative is clearly insufficient to satisfy the requirements of NEPA as reaffirmed in the courts.

Comment Text: A. The Substantial Differences Between Alternative 2 and Alternatives 3 Through 6 Demonstrate the Unreasonableness of the Range of Alternatives. The MRRMP-EIS does not present an adequate range of viable alternatives, rendering the statement inadequate. While each of the six alternatives share management actions to benefit the three species, the substantial differences between Alternative 2 and Alternatives 3 through 6, particularly with respect to habitat construction and the use of AM, demonstrate that the range of alternatives is unreasonable. In addition, Alternatives 3 through 6 are so similar that the only meaningful differences between the alternatives appear in the differences between Alternative 2 and Alternative 3. The MRRMP-EIS therefore violates NEPA by failing to evaluate a reasonable range of alternatives and by leaving unexamined viable and reasonable alternatives that could more effectively utilize a combination of available management actions.

Comment Text: The Executive Summary of the MRRMP-EIS provides the following statement: The purpose of this MRRMP-EIS is to develop a suite of actions that meets ESA responsibilities for the piping plover, the interior least tern, and the pallid sturgeon. Authorities used to meet this purpose may include existing USACE authorities related to Missouri River System operations for listed species and acquisition and development of land needed for creation of habitat for listed species provided by Section 601(a) of WRDA 1986, as modified by Section 334(a) of WRDA 1999, and further modified by Section 3176 Of WRDA 2007 although alternatives formulation was not limited to these authorities. 15 It is unclear whether this statement is intended to be the requisite brief

framing of the Corp's goals because the Corps provides multiple formulations of the project's goals in different sections of the MRRMP-EIS.¹⁶ But even if this statement is the MRRMP-EIS's purpose and need statement, it violates NEPA by failing to provide any guiding criteria for the Corps to determine whether it has met its substantive obligations under the ESA. To correct this shortcoming, the Coalitions urge the Corps to incorporate into the purpose and need statement the primary goals for species restoration and a brief description of the various measures that can accomplish those goals.

Comment Text: The MRRMP-EIS contains a number of shortcomings that are of concern to the State of North Dakota. Among those are that it fails to consider a reasonable range of alternatives under the National Environmental Policy Act (NEPA): the only bird habitat management options evaluated in Alternatives 1 through 6 are really just "sub-alternative" variations in pursuing a singular approach of Emergent Sandbar Habitat (ESH) creation through mechanical and flow means, rather than being inclusive of other bona fide alternative habitat approaches for the birds.

Comment Text: Even more remarkable is the product developed as a result of a great deal of federal resources in terms of employee hours, travel, consultation fees, and overall funds fails to provide a reasonable range of alternatives to meet the agency's responsibility under NEPA and under the Endangered Species Act. The Corps five alternatives numbered two through six should have provided a reasonable range of actions, or collection of actions, designed to recover (not avoid jeopardy which simply means maintaining the status quo) the 3 species over a period of time. The public should be able to compare these alternatives with reference to likelihood of success of recovery (again not jeopardy) and with reference to any other relevant factors the Corp identifies. The DEIS fails to provide information from which the public can make an assessment. At times the information the Corp provides is misleading. The range among alternatives 2 through 6 are inadequate in that there are significant differences between alternative 2 and between the group of 3 through 6. But among alternatives 3 through 6 the differences are minimal. Alternatives 3 through 6 overlap considerably with only minor differences among 3 and 6 are in flow releases prescriptions. But even these differences are minor considering how infrequently the flow releases are likely to occur. For example, alternative 4 includes a spring ESH release, but that is anticipated to fully occur less than one in ten years. Thus, as written Alternatives 3 through 6 are too similar to contribute significantly to the Corps requirement to provide a reasonable range of alternatives.

Comment Text: The language in the Corps' DEIS states that this document is a Missouri River Recovery Management Plan and Environmental Impact Statement, however, the phrase "Missouri River Recovery Management" is quickly replaced by terms describing this EIS as a decision document designed to avoid jeopardy to the federally listed species due to actions by the Corps in carrying out its responsibilities of the Missouri River Bank Stabilization and Navigation Project (BSNP). Unfortunately this document fails miserably at addressing Missouri River Recovery, and in no way provides a blueprint for recovery of the three (3) listed species driving the EIS. Sadly, the never ending saga of Missouri River management in context with the widely recognized need to mitigate the immense damages the BSNP has caused to the Nation's longest river, as well as the statutory responsibilities under the Endangered Species Act (ESA) remains hollow these long number of years since the revision of the Master Manual after the great flood of 1993. Some 24 years later, the Corps refuses to demonstrate coherent understanding of ecosystem science that has been developed over the last quarter century and refuses to taking on the responsibility of incorporating ecosystems services economics and conservation science into the management of the Missouri River.

Comment Text: Our comments on the six alternatives are predicated on background gained from those who live and work along the Missouri River. We can attest to their ongoing frustration with the U.S. Fish and Wildlife Service (USFWS) and the U.S. Army Corps of Engineers (Corps) over the continued uncertainty of river management. Many believe Adaptive Management is a synonym for experimenting on private property. Ongoing disagreements over the construction of shallow water habitat (chutes) in Missouri have called into question the agencies desire to find commonsense ways to enhance habitat for the pallid sturgeon. To put it succinctly, it is difficult to point to progress despite spending \$825 million on the recovery program since 1992.

Comment Text: Indeed, the proposed MRRMP-EIS states Risk and uncertainty are inherent with any model that is developed and used for water resource planning. Unforeseen events such as climate change and weather patterns may cause river and reservoir conditions to change in the future. Although the EIS states The project team has attempted to address risk and uncertainty in the Management Plan by defining and evaluating a reasonable range of plan alternatives that include an array of management actions within an adaptive management framework for the Missouri River. All of the alternatives were modeled to estimate impacts to fish and wildlife, I believe the proposed plan alternatives cannot in any effective way counter the vagaries of variations in river flow that have been and will continue to be experienced in the Lower Missouri River Valley. These vagaries are reflected in the highly variable census data shown in Fig 3-29 of the MRRMP-EIS, Volume 2, and will mask any effects of the plan alternatives. Thus, in my opinion the less done on the river ostensibly in order to reduce jeopardy the better; the futures of Piping Plover and Least Tern are not dependent on conditions on the Lower Missouri River.

Correspondence Id: 166 **Comment Id:** 644875 **Coder Name:** jgutierrez

Comment Text: We were surprised not to find "Dam Safety" discussed as one of the primary risk categories. During the summer of 2012, the Corps completely shut off Missouri River flows at Gavins Point dam in order to study possible damages done to the dam by the 2011 flood flow rates. There was little notice, and no public comment. Risks became observed realities for cultural resources. Mussel populations downstream were left stranded out of water for a couple of days. It would have been a good time to look for these mussel populations, and study the effects; but no study was done that we can see reported in peer reviewed journals. More importantly, dam safety at Fort Peck and each of the down stream dams is seen as a Corps' primary critical mission. Yet, budget and time constraints did not allow sufficient resources to do the Monte Carlo simulations necessary for this critical mission in this DEIS.

Comment Text: Flow rises in other alternatives raise questions about implementations, as those actions require amending the Master Manual. We oppose such revision because the time involved, the risk to the species and the potential for litigation during which time the species could decline even further. Should the Corps choose something other than alternative 3, the process for creating flow changes needs to be clear to stakeholders and be aligned with the Master Manual. For the same reasons, any adaptive management actions could cause concern. Whenever new actions are proposed or existing actions are modified, including those outside the Record of Decision, they must be subject to thorough review, including public comment and EIS impact assessments and be in compliance with the Master Manual.

Comment Text: In light of some of the most dramatic differences in the management actions, especially between Alternative 2 and Alternative 3 through 6, the Corps should not wait until after the selection of an alternative to reinitiate consultation. Rather, consultation should serve to narrow the range of reasonable alternatives based on updated scientific data (while of course maintaining the flexibility associated with a robust AM plan). It is therefore reasonably assumed that the MRRMP-EIS would not only benefit from an updated BA and subsequent BiOp containing new RPA's before any decision on the EIS is rendered, but that the MRRMP-EIS violates both the ESA and NEPA by failing to initiate consultation until after the Corps decides which course of action to take.

Comment Text: The CPR has long been opposed to Master Manual revisions to accommodate environmental flow experiments that could have adverse effects on lower Missouri River stakeholders. To highlight congressional interest in this topic, we wish to remind the Corps of the December 17, 2015 letter to former Assistant Secretary Darcy, signed by 20 members of the U.S. Congress from across the basin, in which they stated: Due to our concerns regarding the current process, we strongly urge the Corps and FWS to only pursue a management plan that would not necessitate a revision of the Master Manual or incur damaging impacts to stakeholders and landowners.

Comment Text: Section & Page Number: 2.5.4, p. 2-31 - 2-32 Comment: This section is about habitat creation in accordance with WRDA 1986, 1999, and 2007, and only describes habitat development for pallid sturgeon in the lower basin of the Missouri River. Section 3176 of the Water Resources and Development Act (WRDA) of 2007 authorizes the Secretary of the Army to use recovery funds in the upper basin of the Missouri River, including the states of Montana, Nebraska, North Dakota, and South Dakota. It is our understanding that guidance has not been developed for this section of the WRDA of 2007, which may prove vital in expanding the geographic scope of the MRRMP-EIS. Guidance should be developed for Section 3176 of the WRDA of 2007 that allows the USACE to implement actions which, based on science, will avoid jeopardy and contribute to recovery of the listed species - regardless of whether or not the action is on the mainstem of the Missouri River.

Comment Text: Section & Page Numbers: 1.6.2, p. 1-27; 2.1, p. 2-1; 2.2, p. 2-2; 2.10.2, p. 2-93 Comment: In a number of places, the MRRMP-EIS omits references to the states and fails to recognize state governments as sovereign entities that have authority to manage natural resources within their boundaries. We request that the document include specific references to the states and their authorities in this regard. Instances where this is needed include: "AM and NEPA are similar in that each emphasizes collaboration principles and working with stakeholders and Tribes." (1.6.2, p. 1-27) "The goal was to formulate a set of reasonable alternatives to meet the species objectives described in Chapter 1.0 and clearly articulate the effects of those alternatives to provide necessary information to decision makers, stakeholders, Tribes, and the public." (2.1, p. 2-1) "CEMs are frequently cited as a necessary step in formal adaptive management (AM), in which stakeholders, Tribes, and scientists jointly develop a shared understanding of what

influences an ecosystem or population, and then apply the model to predictions of system behavior (i.e., hypotheses) under management scenarios." (2.2, p. 2-2) "This action would require extensive coordination with the Tribes in developing site-specific plans for construction in the Garrison Reach in order to avoid sensitive areas." (2.10.2, p. 2-93)

Comment Text: The second basis for our comments is the implementability of the proposed alternatives. The Corps has a history of implementing structural changes to the river, such as shallow water habitat (SWH), yet has failed to achieve mandated changes in flows from the reservoirs that could benefit pallid sturgeon recovery. The Corps has failed to fully implement any flow related Reasonable and Prudent Alternative (RP A) as legally required for the pallid sturgeon in the 2000 and 2003 Biological Opinions from their sister agency, the U.S. Fish and Wildlife Service.

Comment Text: Maintaining Existing Flood Control and Navigation is Paramount Throughout this process the State of Missouri's message has been clear and consistent: flood control and navigation are the primary purposes of the Missouri River Mainstem Reservoir System (System). These purposes were established by Congress in the 1944 Flood Control Act and must not be diminished or undermined. Northwest Deputy Division Commander Colonel Torrey DiCrio clearly articulated this very point during his presentation at the February 2017 Missouri River Navigators Meeting in Kansas City, Missouri. Even though NEPA requires the Corps to analyze a broad range of alternatives, most of the alternatives presented in the DRAFT EIS are inconsistent with the Corps' authority given the impacts they would have to flood control and navigation. As the Corps considers which actions it will ultimately implement, Missouri asserts the agency must insure that such actions are consistent with existing Congressional authority and established priorities.

Comment Text: Corps staff also has indicated the agency may pursue a deviation from the Master Manual for a one-time flow event, rather than changing the Master Manual altogether. The Corps cites Engineering Regulation 1110-2-240 as its authority to deviate from the water control plan. But ER 1110-2-240 only describes the process by which a deviation can be sought and does not grant the authority to do so. A deviation from the Master Manual for such experimental purposes is not consistent with the Corps' Congressional authority and it should not be pursued.

Comment Text: Missouri Objects to Changes to the Master Manual In order to implement Alternatives 2, 4, 5, or 6, the Corps would have to change the existing Missouri River Mainstem Reservoir System Master Manual. Corps staff has asserted that the DRAFT EIS analysis would provide the National Environmental Policy Act (NEPA) coverage to make such changes to the Master Manual. The State of Missouri., however, asserts these proposed significant and controversial changes to the Master Manual would require a separate and distinct NEPA process in order to fully characterize the implications. To highlight the significant public interest in the possibility of Master Manual changes, twenty members of Congress have communicated their concern to the Corps and urged the agency to pursue an alternative that does not require such a change to the Master Manual (see "Master Manual Congressional Letter 121815" enclosed).

Comment Text: There is a lack of mitigation in the Preferred Alternative, although the Corps recognizes that mitigation obligations still exist. In relation to how well the DEIS addresses all species in view of the Fish and Wildlife Coordination Act, a failing to include mitigation has been found. This DEIS is not to over-ride/modify the original EIS which contains the mitigation requirement, however the absence of even a reference to mitigation is troubling. Does the Corps hope to be able to gain momentum in deemphasizing and downsizing it. The Corps coverage of mitigation in the Executive Summary, which is all that most of the public reads, is minimal. It is as if the Corps would prefer to avoid the topic with the public, and not discuss the role mitigation has towards species recovery and restoration. This is not acceptable. The Corps must re-write the DEIS and include mitigations habitat planning.

Comment Text: The Water Resources Development Act (WRDA) of 2007 had asked for the recovery of listed and native species of the Missouri River and a study of the ecosystem. This was Congresss request. A stakeholder group, Missouri River Recovery Implementation Committee (MRRIC) was also established by the act to help provide guidance to the US Army Corps of Engineers (Corps), and the US Fish and Wildlife Service (USFWS). I (Marian Maas, Ph.D.) have served as a stakeholder on MRRIC for Water Quality since its inception. After several years the Corps developed MRAPS and MRERP to help carryout the requirements of WRDA. MRERPS was the study called-for to examine the habitat from bluff-to-bluff, and MRAPS was to examine the Authorized Uses. Unfortunately there were particular interests, many who sat on MRRIC, who did not want these studies to proceed, and their lobbying in Congress resulted in the defunding of the studies and their elimination despite the fact that the Corps had collected considerable data, especially for MRERP. A narrowing of recovery - avoidance of jeopardy - and the rise of Human Considerations in place of MRAPs The Corps changed direction after this and drastically reduced the extent of recovery. The Corps now only wants to avoid jeopardy of the three threatened and endangered species - a much more narrow effort and fails to carry-out the intent of WRDA 2007. No longer is the ecosystem nor any of the other native species part of the Recovery Program. This was an immense diminishment of the Corps Recovery efforts and of the intent of the 2007 WRDA. The Corps unilaterally made this change. It is a reasonable question to ask if this was a legally acceptable change?

Comment Text: Although the Corps references acquired acres for mitigation could play a role in any of the alternatives, it is only in Alternative 2 that the real value of that process is grudgingly given any sanctioned role in recovery. Moreover, this failure to include "mitigation" schedules and requirements expressed in Alt 2 harms the legal meaning of "mitigation" as a construct in ways that- - if left unchanged- - will require clarification in other forums. While the Corps makes clear that the BSNP Mitigation Plan stands on its own authority, it is difficult to see how the Corps will be able to ask the President or congress for budgetary appropriations for this purpose if Alt 2 is not, in some variation, a part of the selected alternative. The reduction of value and function of habitat diversity that necessitated the BSNP Mitigation language in 1986 and 1999 has partly contributed to the decline of pallid sturgeon, terns and plovers on the lower Missouri River, as the Corps indicates many times in this DEIS.

Comment Text: USACE is selecting what it believes to be possible and not what it has been directed to do previously by Congress and what needs to be done for the Missouri River. Section 5018 of Water Resources Development Act of 2007 states USACE shall conduct a study in consultation with MRRIC: "to mitigate the losses of aquatic and terrestrial habitat; to recover the federally list species under the Endangered Species Act; to restore the ecosystem to prevent further declines among other native species." To contrast, the draft MRRMP-EIS is a document to only provide: "a programmatic assessment of 1. major federal actions necessary to avoid a finding of jeopardy to the pallid sturgeon (*Scaphirhynchus a/bus*), interior least tern (*Sterno antillarum atha/assos*), and the Northern Great Plains piping plover (*Charadrius melodus*) caused by operation of the Missouri River Mainstem and Kansas River Reservoir System and operation and maintenance of the Missouri River Bank Stabilization and Navigation Project (BSNP) in accordance with the Endangered Species Act (ESA) of 1973, as amended; and 2. the Missouri River BSNP fish and wildlife mitigation plan described in the 2003 Record of Decision (ROD) and authorized by the Water Resources Development Act (WRDA) of 1986". A directive to assess how to mitigate losses of habitat, recover the listed species and restore the ecosystem was selectively narrowed to identify actions to only avoid jeopardy and evaluate an already established plan. The draft MRRMP-EIS cannot and should not be viewed as fulfilling the study directive detailed in Section 5018.

Comment Text: Under the Flood Control Act of 1944, Congress authorized the Corps to govern the U.S. waterways. Additionally, this act required the Corps to prioritize flood control and navigation as dominant functions of its authority. Though the responsibilities of the Corps have increased over time with additional directives from Congress, namely those to assist in protecting endangered species, the new obligations have not diminished the original priorities. While the courts have noted the difficulty in balancing these varied interests, case law is clear that endangered species do not get to take precedence to the detriment of flood control and navigation. Thus, while it is a painstaking task, it is nonetheless imperative the Corps find a fair balance for these complex issues.

Correspondence Id: 177 **Comment Id:** 644635 **Coder Name:** jgutierrez

Comment Text: The Introduction describes that the EIS is prepared as a programmatic assessment of evaluate major federal actions on: Endangered Species affected by the reservoir system; and the Bank Stabilization and Navigation Project (BSNP); as well as on the BSNP Fish and Wildlife Mitigation Project (Mitigation Project) authorized by Congress. U.S. Army Corps of Engineers (USACE) funded the Mitigation Project for the BSNP from federal Fiscal Year 1992-2005. With an amended Biological Opinion (2003), the USACE added a second program known as 2003 Biological Opinion Implementation, which retained separate allocation from federal Fiscal Year 2004-2005. In Fiscal Year 2006 and subsequently, these programs were combined as the Missouri River Recovery Program, funding was co-mingled, and the proportion of funds budgeted or spent for meeting the USACEs Mitigation Project responsibility was significantly reduced. While the Mitigation Project can be complimentary and beneficial to Endangered Species Act (ESA) compliance, it is designed to be a tool for Clean Water Act, Section 404 compliance. Elimination or significant modification of Mitigation Project activities from the MRRP would seem to constitute a major program change. Without a component of the Mitigation Project dedicated to sport and other native, non-endangered species, it is unclear how such program changes might continue to meet the USACEs responsibility for compensatory mitigation from the BSNP project to Missourians and the nation.

Comment Text: Since 1986, the Corps has been authorized by Congress to acquire up to 166,750 acres of land and construct habitat to mitigate for fish and wildlife losses resulting from construction of the Missouri River Bank Stabilization and Navigation Project. This authorization, if completed, would replace only 32% of the 474,600 estimated acres of habitat lost between 1912 and 1980. Approximately 66,000 acres of land has been acquired to-date. This acquisition constitutes only 39% of that authorized by Congress and 14% of the estimated habitat lost as a result of the construction and maintenance of the BSNP. We encourage the Corps to confirm its commitment to continued execution of the BSNP Mitigation Project separately from the Corps' overall efforts to comply with the ESA. Critical to the Mitigation Project is a resumption of property purchase from willing sellers and habitat development within the meander belt to benefit all native species. Perhaps the Record of Decision could confirm the Corps commitment to continued acquisition of quality restoration sites specifically under the BSNP Mitigation Project to benefit native fish and wildlife species. Continued execution of this project provides a template for future implementation of new actions to recover listed species called for under the AMP and will support a reduction in flood risk to private property.

Correspondence Id: 183 **Comment Id:** 643939 **Coder Name:** jgutierrez

Comment Text: As addressed on page 1-7 of the Draft MRRMP/EIS, the 2003 BSNFWMP was authorized by Congress to mitigate for the 522,000 acres of fish and wildlife habitat lost between 1912 and 1980 due to construction of the Bank Stabilization and Navigation Project (BNSP) (USACE 2003) with habitat restoration of 48,100 acres. Section 334 of WRDA 1999 increased the acreage of habitat to be mitigated for the BSNFWMP by 118,650 acres, bringing the total acres to be mitigated to 166,750 acres. It has taken 14 years to acquire land in fee title or easement to restore approximately 66,000 acres of habitat (approximately 40%) of the required 166,750 acres BSNP mitigation lands. Habitat types to be restored include wetlands, bottomland forest, native prairie, chutes and side channels, shallow water habitat (SWH), backwater areas, and slack water habitats. To date, the obligations of the BSNFWMP have not been completed, but are still relevant and remain unchanged (Page 1-14), over 100,750 acres still need to be acquired. The USFWS recommends the Final EIS address the continued commitment to acquiring these mitigation lands.

Comment Text: The Draft MRRMP/EIS (Page 1-1) states that this document is a programmatic assessment for two purposes, (1) major federal actions necessary to avoid jeopardy of the three listed species and (2) implement the BSNFWMP described in the 2003 Record of Decision (ROD) and authorized by the Water Resources Development Act (WRDA) of 1986, 1999, and 2007. The Draft MRRMP/EIS (Page 1-7, Section 1.1.5) further states that the MRRP is the umbrella program that coordinates the Corps efforts in three programs, one being "Acquiring and developing lands to mitigate for lost habitats as authorized in Section 601(a) of WRDA 1986, and modified by Section 334(a) of WRDA 1999 (collectively known as the BSNFWMP)." Although, the Corps has stated that everything they are proposing to do for the listed species is consistent with and contributes to the BSNFWMP, the USFWS is concerned that the Draft MRRMP/EIS does not fully described how the Corps proposes to do that, nor what actions they will engage

in to further the BNSFWMP. The USFWS recommends that the Final EIS fully disclose how the Corps will meet their FWCA mitigation responsibilities for all native fish and wildlife species habitat on the river during implementation of the MRRP, and consider the adverse impacts to non-federally listed species by focusing habitat mitigation to only listed species for the next 15 years.

Comment Text: One important tool for this aspect of Recovery is the Mitigation Program referenced in the DEIS. Estimates of public property lost to Missouri River modifications in Kansas top 55,000 acres of which only 6,100 has been replaced by 5 Missouri River Mitigation sites. There must be continued acquisition of additional property from willing sellers to mitigate for the thousands of acres of lost habitat. This also represents the land base necessary to provide habitats necessary for Recovery while preserving other existing uses of the river.

Comment Text: In addition, if Preferred Alternative 3 is approved, at the end of 15 years with just the minimal amounts of spawning and interception habitat added, the BSNP Congressional authorization of 166,750 acres would still need to be met. According to the 2015 Biennial report to Congress on the status of the Missouri River BSNP Project by the Assistant Secretary of the Army for Civil Works in Accordance with Section 4003 (e) of the Water Resources Reform and Development Act of 2014, 66,616 acres have already been acquired. That leaves a little over 100,000 acres left to meet Congressional authorization. Since a Final Supplemental EIS was already completed in March 2003 for this project, it is paramount that Congressional intent be followed to compensate the States for the loss of 522,000 acres of aquatic and terrestrial habitat. We believe creating habitat and avoiding jeopardy to the pallid sturgeon can occur concurrently. Concurrently pursuing habitat and avoiding jeopardy to pallid sturgeon as described above would seem to be a prudent path to follow. The Nebraska Game and Parks Commission fully believes that systematic top-width widening is the only practical means to create the amount of functional habitat necessary to support Pallid Sturgeon and the ecosystem on which they depend.

Comment Text: Section & Page Number: 6.5, p. 6-4 - 6-5 Comment: The "Water Rights" section does not mention state water rights. Each state has its own way of addressing water use and control. In the Enabling Act, Congress provided for the people of the Dakota Territory to form constitutions and state governments and be admitted into the union on an equal footing with the original states.¹ In North Dakota, the constitution provides that "[a]ll flowing streams and natural watercourses shall forever remain the property of the state for mining, irrigating and manufacturing purposes."² This constitutional language was adopted through the Enabling Act by proclamation of the President when North Dakota was declared a state in 1889.³ "A right to appropriate water can be acquired for beneficial use only as provided in [chapter 61- 04]. Beneficial use shall be the basis, the measure, and the limit of the right to the use of water."⁴ Throughout history, Congress and the Supreme Court have spoken with a clear and consistent voice regarding state deference with respect to water allocation. As the Court observed in the landmark California v. United States decision: The history of the relationship between the Federal Government and the States in the reclamation of the arid lands of Western States is both long and involved, but through it runs the consistent thread of purposeful continued deference to state water law by Congress.⁵ ¹ Enabling Act

of 1889, 25 Stat. 676, ch. 80. 2 N.D. Const. art. XI, Â§ 3. 3 See Enabling Act of 1889, 25 Stat. 676, ch. 180, Â§ 8. 4 N.D.C.C. Â§ 61-04-01.2. 5 438 U.S. 645, 653 (1978).

Comment Text: TNC is concerned with the lack of specific actions related to acquiring and developing lands associated with the Bank Stabilization and Navigation Project (BSNP) Mitigation Project authorities in the draft MRRMP-EIS and current Preferred Alternative. Although the Preferred Alternative does note the inclusion of “riparian habitat development on any acquired land”, the MRRMP-EIS seems to lack any detail on the amount of acquired land would occur or the types of habitat development. TNC has been and remains supportive of the acquisition and development of lands to mitigate for lost habitats as authorized in Section 601(a) of WRDA 1986 and modified by Section 334(a) of WRDA 1999 and agrees with the USACE characterization in Volume 1 of these authorities being obligations of the Fish and Wildlife Coordination Act. TNC observed at the public comment meeting held in Omaha on the draft MRRMP-EIS two out of the three self-identified agricultural based landowners who provided public oral comments described how they wanted and were willing to participate in restoration activities along the river.

Comment Text: USACE is selecting what it believes to be possible and not what it has been directed to do previously by Congress and what needs to be done for the Missouri River. Section 5018 of Water Resources Development Act of 2007 states USACE shall conduct a study in consultation with MRRIC: "to mitigate the losses of aquatic and terrestrial habitat; to recover the federally list species under the Endangered Species Act; to restore the ecosystem to prevent further declines among other native species." To contrast, the draft MRRMP-EIS is a document to only provide: "a programmatic assessment of 1. major federal actions necessary to avoid a finding of jeopardy to the pallid sturgeon (*Scaphirhynchus albus*), interior least tern (*Sterna antillarum athalassos*), and the Northern Great Plains piping plover (*Charadrius melodus*) caused by operation of the Missouri River Mainstem and Kansas River Reservoir System and operation and maintenance of the Missouri River Bank Stabilization and Navigation Project (BSNP) in accordance with the Endangered Species Act (ESA) of 1973, as amended; and 2. the Missouri River BSNP fish and wildlife mitigation plan described in the 2003 Record of Decision (ROD) and authorized by the Water Resources Development Act (WRDA) of 1986." A directive to assess how to mitigate losses of habitat, recover the listed species and restore the ecosystem was selectively narrowed to identify actions to only avoid jeopardy and evaluate an already established plan. The draft MRRMP-EIS cannot and should not be viewed as fulfilling the study directive detailed in Section 5018.

Comment Text: The State of North Dakota has serious concerns with respect to potential changes to or deviation from the Master Manual. The MRRMP-EIS includes alternatives with several flow management actions that would deviate from the current Master Manual. The Adaptive Management Plan (AMP) adds another layer of uncertainty due its lack of sideboards and vagueness in how the state would be involved in the decision-making process if the Master Manual were to change. The last update to the Master Manual took over 15 years to complete and caused great discord in the basin. The current Master Manual incorporates flood control and drought conservation measures that are critical, not only for North Dakota, but for the entire basin. It was and still is important to the State of North Dakota that the Missouri River be operated in a manner that equitably shares the pain during periods of drought and equitably distributes the benefits of Missouri River operations. The State of North Dakota adamantly opposes any changes to the contrary. Accordingly, we request that the Final EIS and ROD contain express procedural protections that will govern future

consideration of any proposed flow modifications or deviations outside the bounds of the current Master Manual. These should provide for a direct consultation opportunity with North Dakota (and other affected states) apart from the Missouri River Recovery Implementation Committee (MRRIC), Fish and Wildlife Coordination Act (FWCA), and Annual Operating Plan (AOP) processes, and for additional NEPA compliance prior to a decision to approve any such change.

Organization: State of North Dakota

Correspondence Id: 96 **Comment Id:** 640189 **Coder Name:** jgutierrez

Comment Text: However, even with these shortcomings, North Dakota tentatively supports the Preferred Alternative under the following conditions: (1) Reconvene consultation with the North Dakota Interagency ESH Team on annual activities related to the Missouri River Recovery Program; (2) The final EIS and Record of Decision (ROD) state that any flow modifications outside the bounds of the current Missouri River Mainstem Reservoir System Master Water Control Manual (Master Manual) would require the preparation of an additional EIS, including consultation with affected states; and (3) The final EIS commits the USACE to obeying all applicable state laws, permit and regulatory requirements, and policies. Further explanation of these conditions is provided throughout these comments. North Dakota's tentative support of the Preferred Alternative (Alternative 3) is based on the unacceptability of Alternatives 2, 4, 5, and 6 due to the adverse impacts those alternatives would cause. In addition, the potential model deficiencies are less likely to understate the impacts for Alternative 3 than for the other alternatives.

Comment Text: Declines in native species can be traced largely to these changes. When a species peril is so great it becomes endangered, it is right to look for those critical aspects of habitat it most needs. But it just as critical to look at the entire ecosystem that supports those aspects of habitat. If not we will always be fixing patches of habitat. And those patches will end up being fragile and unsustainable in the absence of a larger recovery. This sadly is the path the Corps has taken in this DEIS. The Corps has a responsibility to mitigate for the BSNP (WRDA1986 and 1999). The Big Muddy Wildlife Refuge system and other areas represent progress in that responsibility. But funds have been stalled. Also the Corps has, in our experience, failed to express full support for this mitigation program. The Corps has failed to promote the need for this program. Within this DEIS it has failed to accurately

measure and promote the value of achieving progress on both its mitigation responsibility and its recovery responsibilities with the same acres.

Comment Text: We believe the purpose and need statement of the EIS does not make its goals sufficiently clear and, as a consequence, does not provide the public with a concise and focused set of objectives for the evaluation of the project alternatives. The Corps provides multiple and potentially conflicting goals in different sections of the EIS. For example, the executive summary states, quote, the purpose of the EIS is to develop a suite of actions that meets Endangered Species Act responsibilities for the piping

plover, the interior least tern, and the pallid sturgeon, end quote. The statement effectively summarizes the Corp's obligation to ensure that the continued existence of the three species is not jeopardized by Missouri River operations. However, the Corps adds within the problem definition section of the first volume of the EIS, rather than the executive summary, that the plans should continue to, quote, serve the Missouri River authorized purposes and accounts for human considerations, end quote. The original purpose specified in the Endangered Species Act becomes subordinate to the EIS's lengthy discussion of human considerations, which consists largely of the economic effects on certain special interests. We are concerned that those considerations, which are not identified within the purpose and need statement, become controlling factors in the ultimate selection of the preferred alternative. What gets lost in translation is how effectively the selected alternatives will actually meet species' goals relative to the other alternatives, or at least a clear statement to that effect at the beginning of the EIS.

Comment Text: Toward the end of directing scarce resources to reasonable alternatives, we request that the U.S. Army Corps of Engineers and the U.S. Fish & Wildlife Service expand the scope of the EIS and the amended biological opinion for the Management Plan to include the Middle Mississippi River. We believe that such an expanded scope is necessary to avoid alternatives whose implementation is remote and speculative and that have little chance of aiding the recovery of the pallid sturgeon. Our request to ensure that the scope of the EIS includes the Middle Mississippi River mirrors the findings of the Missouri River Recovery Program Independent Science Advisory Panel (ISAP), in its Final Report on Spring Pulses and Adaptive Management, dated November 30, 2011 (11-STRI-1482), page 51: Recovery of pallid sturgeon in the lower Missouri River ultimately might not depend on successful recruitment below Gavins Point Dam. Given the minimal extent of low-velocity habitat that exists downriver from Gavins Point Dam,

pallid sturgeon larvae may be transported downstream at rates proportional to discharge, and exit the lower Missouri River. Such potential contributions of larval pallid sturgeon to the middle Mississippi River suggests that the importance of conservation efforts on the lower Missouri River may be realized in sustaining pallid sturgeon in a greater geographic context. Recruitment in areas where pallid sturgeon are known to spawn below Gavins Point Dam likely needs to be inferred from sampling an extensive area of the Missouri and Mississippi river basins. In addition, at page 58, the Final Report on Spring Pulses and Adaptive Management goes on state that the three listed species (pallid sturgeon, interior least tern and piping plover) would benefit from review and integration of data and recovery efforts in an expanded geographic area: The ISAP recognizes that the demographic units of the three listed species, located on the lower Missouri River below Gavins Point Dam, constitute a limited portion of the populations (or metapopulations) in the greater Missouri River system, and that each ecologically interact with conspecific individuals in other areas occupied by the species. For that reason, and to better facilitate the recovery of the listed species, any adaptive management program that includes actions on the lower Missouri River should be integrated with conservation efforts elsewhere in the system, and supported by a synthetic program of data acquisition and analyses that takes advantage of information derived from studies undertaken beyond the focal area considered in this report. This logic supports the expansion of the EIS for the Management Plan to include the Middle Mississippi River. The data collected on pallid sturgeon in the Middle Mississippi is relevant to issues of recruitment for pallid sturgeon that utilize the Lower Missouri River. According to the U.S. Fish & Wildlife Service, Midwest Region, Endangered Species Section 7 Consultation on the Operation of the Upper Mississippi River 9-Foot Channel, there is evidence of natural reproduction: in 1998 a young-of-year pallid sturgeon was collected in the Middle Mississippi River; in 1999, larval pallid sturgeons were collected in the Lower Missouri River; and in 2000, larval pallid sturgeons were collected in the Middle and Lower Mississippi River. The Middle Mississippi River is indeed the core of the pallid sturgeon's range.

Comment Text: The inordinate focus on attempts to reduce jeopardy in the Lower Missouri River (Lewis and Clark Lake down-river to the Mississippi River junction) is a direct consequence of the belief in the 2000 and 2003 BiOps that Piping Plovers consist of several essentially separate sub-populations and that extirpation of any of these must be avoided at all costs. Indeed, the level of interchange of Piping Plovers between the sub-populations was estimated in those BiOps at only 2%, based on an essentially best guess by experts. At that time there were little or no data to support this, or any, estimate of interchange between sub-populations; it is only recently that such estimates have become available. Recent estimates are based on actual data from the Alkali Lakes and Missouri River reservoirs in the northern USA and southern Canada collected by Michael Anteau and colleagues at Northern Prairie Wildlife Research Center, Jamestown, ND Canada, and in Nebraska away from the Missouri River collected by the Nebraska Tern

and Plover Conservation Group, Lincoln, NE. Even though these locations are at opposite ends of the overall Piping Plover range, the interchange data are remarkably consistent despite differing habitats. These studies estimate subsequent-year return rates of successfully-breeding adults at 86.7% and 61% respectively, and 49.9% and 21% respectively. Thus there appears to be widespread dispersal, presumably each year, of 50-79% of the one-year-old potential breeding birds. Although re-sight data are few, they are indicative of movement between the formerly-constituted sub-populations, even to the extent of at least one Nebraska bird reaching the Alkali Lakes in Canada. Of course, Piping Plovers have evolved for some 10,000 years on the Great Plains to adapt rapidly to changing conditions, natural or man-made. Examples of this adaptability are numerous. Lake McConaughy, on the eastern North Platte River in Nebraska is a prime example; during periods of low lake water levels, studies counted as many as 245 nests (Peyton and Wilson, 2007). In high water level years such as 2016, only 10 adults and 9 nests were found when the lake was near full pool (Zorn and Wilson 2016). Anteau (2017) noted that dispersing young Piping Plovers in the northern parts of the species range showed a preference for margins of Alkali Lakes and Missouri River reservoirs. Similarly, extensive use of off-channel habitats (definition below) by Piping Plovers throughout their breeding range also illustrates their impressive innate ability to rapidly colonize newly-formed habitat from one year to the next. Thus, to summarize, current data indicate that there is one interconnected breeding population of Piping Plovers, characterized by Anteau (2017) as being More like a single population with many breeding areas than a meta-population. The overall population is maintained by a marked amount of dispersal, especially by one-year-old potential breeders, in the range of 21-50%. Because of this adaptability, I strongly recommend that the DEIS adopt the one population concept, and cease so-called jeopardy avoidance operations on the lower Missouri River. The latter are a good example of high cost-low return use of taxpayer dollars, implemented solely because of a drastically underestimated degree of dispersal by young Piping Plovers in the 2000 and 2003 BiOps. Further, I strongly recommend that the delisting process be completed for this species.

Comment Text: There is much experimentation regarding pallid sturgeon habitat in the preferred alternative 3. With the acknowledged uncertainty it would be more than prudent to include SWH, IRCs, and spawning habitat all in a preferred alternative. Measuring success for species recovery needs to eventually include designation of critical habitat for the pallid sturgeon. The pallid sturgeon has been listed for nearly 30 years with no habitat designation yet. A petition for critical habitat designation was submitted to USFWS in 2010. The Service responded that it was unable to complete the designation due to workload. As this DEIS demonstrates identification of pallid sturgeon habitat for various life cycle stages is complicated and the subject of ongoing study. A part of all this effort should result in an understanding of population dynamics and location. We encourage the Corps to not overlook any tributary as well as the Missouri river itself. The work put into the DEIS would be incomplete if critical habitat designation remains unresolved.

Comment Text: Currently, the EIS is somewhat narrowly focused on the Endangered Species Act, and within that on age-0 Pallid Sturgeon. The EIS may need to take a broader focus on an ecosystem level to provide benefits to all fish and wildlife and all users in the landscape. There are numerous other species that have documented declines with potential listings in the very near future due to habitat degradation and changes to the river system. Instead of chasing listings, the EIS should take a proactive approach to prevent these declines and future listings from occurring. This ecosystem level approach would likely need to take on much larger and more impactful projects in the watershed that will not only provide benefits to Pallid Sturgeon and fish and wildlife, but also to the users

and landowners within the landscape. Many of Iowa streams have impaired water quality and have had increased floods in recent years due to changes in the Missouri River and its landscape, thus creating habitats that will mitigate these negative effects are necessary.

Comment Text: The role of the United States Army Corps of Engineers (Corps) in producing and implementing the Missouri River Recovery Management Plan is to restore the populations of the piping plover, interior least tern, and pallid sturgeon. The role is not to perform a balancing act between the various commercial interests and the three endangered species. The Endangered Species Act requires the Corps to undertake the most protective actions for those species. It was the Corps whose actions imperiled the piping plover, interior least tern, and pallid sturgeon and placed the on-going existence of those species in jeopardy. And it is the Corps that has the responsibility to restore the habitat along the Missouri River so that these species can continue to exist, to thrive, and to increase their numbers.

Comment Text: TNC acknowledges the Missouri River Ecosystem Restoration Plan effort was stopped by factors largely outside of USACE's control, but it does not eliminate the directive or the need for a broader plan. The draft MRRMP-EIS's focus on the currently listed species is warranted and should advance their recovery if the AMP is diligently followed, but this sole focus will also come at a cost. If USACE does not identify and implement actions to restore the ecosystem to prevent further declines among other native species, it will ensure further declines and eventually other federally listed species. TNC requests that USACE - in consultation with MRRIC - begin a broader Missouri River ecosystem assessment. Ideally this assessment would fulfill the directive of Section 5018 and evaluate how different levels of restoration of the ecological structure (e.g. riverine/floodplain ecosystem, flow regimes, sediment regimes) can also address and modernize dated aspects of infrastructure and operations associated with the authorized purposes. For example, TNC has long been a proponent of coupling river/floodplain restorations at the known lower river "pinch" points. These areas are where at high flows infrastructure located too close to the river increases local river stages. Levees with repetitive failures due to placement over historic river channels are also areas where both ecological and infrastructure restoration

could take place. These are just two examples of science-based, practical solutions that meet the needs of people and nature a broader assessment could identify.

Comment Text: Pallid Sturgeon do not and cannot live in isolation, they are a part of and supported by the ecosystem within which they evolved. As a predator at the very top of the Missouri River aquatic food chain they are even more intrinsically linked to the health of the ecosystem within which they live than many of the species upon which they depend. Therefore, the Nebraska Game and Parks Commission believes that any plan to avoid jeopardy for Pallid Sturgeon should include a significant habitat restoration and management plan targeted at the specific habitat needs of all of the life stages of Pallid Sturgeon (spawning, drift, interception, and rearing) and that this plan would be inadequate if it did not also include habitat restoration and management to support the native fish community necessary to support a healthy, reproducing population of this top predator.

Comment Text: The designation of the upstream extent of the action area at Fort Peck Dam ignores effects of USACE operations on Pallid Sturgeon in the Missouri River upstream of the impoundment in the section of the Great Plains Management Unit, formerly known as Recovery Priority Management Area 1 (RPMA 1). The 2000 Bi Op explicitly states that USA CE operations affect " ... the area of the Missouri River and its reservoir system from the headwaters of Fort Peck Lake in Montana," and the subsequent absence of this designation in the current BiOp, as amended, has not been justified. As the 2000 BiOp notes, " ... the point furthest upstream where the Corps [USA CE] regulates Missouri River flows is at [U.S. Bureau of] Reclamation's Canyon Ferry Dam in Montana,". Under the Flood Control Act of 1944 the USACE has regulation requirements for two non-USACE projects, Canyon Ferry Reservoir and Lake Elwell (Tiber Reservoir), that influence flows in the Marias River and Missouri River in RPMAL.

Correspondence Id: 236 **Comment Id:** 643305 **Coder Name:** jgutierrez

Comment Text: Under 33 CFR 208.11 (b): Responsibilities ... The basic responsibilities of the Corps of Engineers regarding project operation are set out in the cited authority and described in the following paragraphs: (1) Section 7 of the Flood Control Act of 1944 (58 Stat. 890, 33 US. C. 709) directs the Secretary of the Army to prescribe regulations for flood control and navigation in the following manner: Hereafter, it shall be the duty of the Secretary of War to prescribe regulations for the use of storage allocated for flood control or navigation at all reservoirs constructed wholly or in part with Federal funds provided on the basis of such purposes, and the operation of any such project shall be in accordance with such regulations ... As recently as 2011, the USA CE exercised its operations authority of Tiber Reservoir for flood control and navigation in waters downstream of Tiber Dam and likely outside of Montana. During this event, flows in the Marias River were held back which caused massive flooding in the Tiber Dam forebay. Had the USACE not intervened, the flows in the Marias and Missouri rivers in RPMA 1 would have been much higher and would have mimicked the natural flow regime during normal spawning periods for Pallid Sturgeon and a host of native fishes. As such, it is clear the USA CE has water flow operational authority in RPMA1 and those actions have influenced the natural habitat of Pallid Sturgeon. Determination in avoidance of jeopardy to Pallid Sturgeon through USA CE actions in the MRRMP-EIS is incomplete without accounting for impacts to the species in RPMA 1. Under their respective obligations to avoid jeopardy to the species and to ensure instances of "take" are accounted for under the restrictive management and protections of the ESA, the USACE and the USFWS need to evaluate these effects. Considering these factors, the State recommends the MRRMP-EIS include the Missouri River upstream of Fort Peck Dam.

Comment Text: The decline in the biological community of the Missouri River is well documented with 3 species currently listed. In addition, a large number of additional species are known to be in decline. The underlying issue in the decline of these communities is habitat, and if the Corps is to succeed in restoring this ecosystem, it will only be accomplished through habitat. As the DEIS points out, in broad terms the system is roughly 1/3 natural (with modifications), 1/3 impounded or heavily influenced by impoundments, and 1/3 (735 miles) channelized. The result is a highly modified system from a physical habitat perspective and a modified flow regime. With this extent of alteration the Corps must focus efforts on habitat restoration for there to be any chance of success. We are not suggesting that other related efforts, such as studies, monitoring and evaluation are not valuable tools. They are valuable, and many tools will be needed, but on the ground habitat must be the focus. Recent budgets, discussions at meetings and the emphasis within this document do not give us confidence that on the ground habitat is the focus of this effort at this time.

Comment Text: As the result of ongoing research, appears there may be potential for survival/recruitment of larval pallid sturgeon within the Missouri River below Fort Peck Dam (Ryan Wilson. pers. comm. 2017). The USFWS encourages consideration of MRRP actions within that reach of the Missouri River, pending the additional information and subsequent review. The following are examples of potential actions the Corps should consider to expand the scope of the MRRMP/EIS: • Flow and temperature modifications - utilize surface water discharges from Fort Peck and Fort Randall Dams to increase river water temperatures; Implement summer low flows from Gavins Point, Fort Randall, and Fort Peck dams to increase seasonal water temperature and habitat heterogeneity; • Discontinue hydro-peaking from Fort Peck and Fort Randall dams to increase recruitment of pallid sturgeon; • Increase floodplain connectivity to allow for nutrient and sediment inputs; • Implement top-width widening to increase organic and sediment input and habitat diversity.

Comment Text: The USFWS recommends the Corps include the reach between Gavins Point Dam and Fort Randall Dam within the geographic scope of the Draft MRRMP/EIS and adaptive management plan. This reach of Missouri River has and continues to be profoundly impacted by operation of the dams through alterations to hydrologic regime, temperature regimes, and sediment regimes, for example. A significant number of pallid sturgeon (12,000) have been stocked in this reach, with nearly all year classes represented. The survival and growth of hatchery reared fish is similar to other reaches. Despite effects of the operations of the mainstem dams, portions of this reach still provides the type of natural habitat complexity that are highly altered or absent elsewhere in the basin. The habitat complexity developed downstream of the Niobrara River confluence is the size and scope that likely retard and delay the drift of larvae or perhaps even intercept larvae. If larval fish move downstream through the delta and reservoir, they may contribute to recruitment in the lower Missouri River. At this time, few fish are reproductively mature, but as more hatchery reared fish reach sexual maturity, this reach will warrant more detailed monitoring to determine the role that this population and river reach play in achieving the MRRP objectives.

Comment Text: Comment 1: The geographical range of the DEIS should be expanded to include the reach of the Missouri River above Fort Peck Reservoir and the Yellowstone River upstream of Intake Dam, including at least the lower reach of the Powder River and, perhaps, as far as the Big Horn River. The geographical range of the DEIS should include the reach of the Missouri River above Ft Peck Reservoir because: 1) This reach of river is designated as Recovery Priority Management Area 1 by the USFWS. 2) Fragmentation by dams is identified as a limiting factor in the pallid sturgeon recovery plan. 3) Entrainment of free embryos into downstream anoxic reservoir habitat is strongly suspected of preventing recruitment in RPMAs 1 and 2 since the two dams (Ft Peck & Garrison) were closed. 4) The effects of Fort Peck Reservoir on the upstream pallid sturgeon population (genetic isolation from other pallid sturgeon, inundation of fluvial pallid sturgeon habitat, mortality of drifting free embryos and others) are completely ignored. Although Chris Guy's report of the anoxic conditions in Fort Peck Reservoir are used in the DEIS to document anoxic conditions in the headwaters of Lake Sakakawea, the effects on pallid sturgeon above Fort Peck Reservoir are ignored. Further, the need to ameliorate these impacts are ignored. 5) Had the USFWS designated critical habitat for pallid sturgeon it is unlikely that RPMA 1 would have been excluded from consideration in the USACE's DEIS. The geographical range of the DEIS should include the Yellowstone River above Intake Dam because: 1) Telemetered pallid sturgeon have been documented as using an existing side

channel to pass beyond Intake Dam., thus it is not a complete barrier. 2) Pallid sturgeon have been documented to spawn in the lower Powder River. 3) There is photographic evidence of historic use of pallid sturgeon of the Big Horn River.

Comment Text: Although USACE believes it has done its due diligence to eliminate from consideration any modifications at Fort Peck Dam to provide flows and temperatures, "take" of pallid sturgeon will continue in the Missouri River between Fort Peck Dam and Lake Sakakawea due to the effects of unnatural flows and temperatures on pallid sturgeon and their habitats caused by the hypolimnetic discharge from Fort Peck Dam. Further, this leaves the Yellowstone River as the only potential source of recruitment in RPMA 2, which a 2016 Upper Basin workshop exercise predicts is unlikely. There are measures that could be taken that would attract spawning pallid sturgeon to spawn below the mouth of the Milk River and achieve survival of at least a portion of the resulting free embryos. Recommendations will be forthcoming from Montana pallid sturgeon experts that accomplish exactly this.

Comment Text: Comment 6: Based on the paucity of management action proposed to address the USACE-caused factors limiting pallid sturgeon in Montana, I can only conclude that the USACE's intent is to use taxpayers' money to delay substantive operational

and infrastructure changes for the benefit of pallid sturgeon and their habitats. Although the Intake Dam project may provide fish passage above that structure, the potential for achieving natural recruitment from the Yellowstone River is highly suspect, as telemetry studies suggest pallid sturgeon have periodically pass and spawn upstream of Intake Dam since its construction but recruitment has not occurred since the closing of Garrison Dam. It is both biologically unsound and inconsistent with the purpose of the Endangered Species Act for the USFWS to not require the USACE to address pallid sturgeon limiting factors in both the Missouri and Yellowstone rivers, including the reach of the Missouri River upstream of Fort Peck Reservoir which is designated as a recovery priority management area by the USFWS.

Comment Text: Recent science papers (Guy CS, Treanor HB, Kappenman KM, Scholl EA, Ilgen JE, Webb MA. 2015. Broadening the regulated-river management paradigm: a case study of the forgotten dead zone hindering Pallid Sturgeon recovery. Fisheries 40(1): 6-14. DOI:10.1080/03632415.2014.987236) have identified anoxic, lethal conditions in the reservoirs below, and above, Fort Peck dam. The full geographic range of jeopardizing conditions for all three species should be included and studied as part of a comprehensive, scientific evaluation; not just the downstream effects. Operations and management at Fort Peck could increase larval drift distances and may even improve, or at least move, the anoxic zones in that reservoir. The Corps should not ignore this proximate cause of jeopardy to pallid sturgeons identified. Likewise, the full and extended range of new spawning habitat afforded by fish passage at the Yellowstone Intake Project should be included as part of the current DEIS. It is ironic that the Corps' solution to partial fish impassability at Intake, MT is to build a taller dam. The Corps and Bureau of Reclamation should share full responsibility for the success, or failure, of this project in its final form. That shared responsibility should have been considered within the geographic footprint of this DEIS, as it is not. The purpose and need statements do not reflect the full geographic range where the Corps has both authority and current management actions.

Comment Text: The scope received another major curtailment or contraction in the Corps decision to tailor this DEIS, and restrict it to the sole aim of "avoiding jeopardy". The effect has been to move from a "greatest benefits" utilitarian model for the 8 authorized purposes, to a "least cost" model. When combined with the metaphysical regulatory language found in the 1983 Planning & Guidance documents, the net effect is to move from maximizing utilitarian benefits to minimizing or avoiding costs. " The intent of the Pick-Sloan Plan was to secure the maximum benefits for flood control, irrigation, navigation, power, domestic, industrial and sanitary water supply, wildlife, and recreation (Senate Document 247, quoted in Weeks et al. 2005). The results of the Pick-Sloan Plan represent the most important and lasting alteration of the Missouri River ecosystem (Weeks et al. 2005)." (Stark, et al. - - Stark, K.J., L.J. Danzinger, M.R. Komp, A.J. Nadeau, S. Amberg, E. Iverson, D. Kadlec, and B. Drazkowski. 2011. Missouri National Recreational River: Natural Resource Condition Assessment. Natural Resource Report NPS/MNRR/NRR-2011/476. National Park Service, Fort Collins, Colorado.) A major deficiency created by this policy decision to restrict considerations to "avoiding jeopardy" is to move from multivariate science questions (the Big questions) to causative assign-ability or liability questions while deferring some testable hypotheses (aka the "Reserve Hypotheses") based on jurisdictional or appropriational authorities. Whether any, or which, of these hypotheses might have survived a structured decision making process to enter the pool of "dominant hypotheses" is a topic of irrelevant speculation in hypothetical counterfactuals. The Reserve Hypotheses are off the table for consideration until such time as all policy-accepted hypotheses have been exhausted. Thinking within this smaller scope creates new and different kinds of "jeopardy" for the three species, if it should emerge that some reserve hypothesis turns out to be the critical, scientific issue that might have been considered during a time-critical window. These endangered species deserve our collective best and effective effort. They may not survive the 15 year calendar timelines, or 50 year period of analysis, contained in the DEIS.

Comment Text: First, the restrictions in scoping are the subsequent product, as interpreted through Regulation by the Agencies, of the Congressional decision not to appropriate resources for the study authorized in WRDA 1986, . 1850 ss. A. This DEIS does not contain any semblance of an "ecosystem restoration" study (MRERP), neither does it valueate or reconsider any of the 8 Authorized Purposes (MoRAP)- - those studies might have led to different results in avoiding jeopardy for the three species. As importantly, the Human Considerations elements would likely have had different outcomes if either, or both, of those studies were before us now for

comment. They are not. As such, it remains for future reconsideration whether an ecosystem restoration or landscape conservation approach will be required to recover the species, rather than just avoiding jeopardy, as the Agencies have asserted in past documents.

Comment Text: TNC acknowledges the Missouri River Ecosystem Restoration Plan effort was stopped by factors largely outside of USACE's control, but it does not eliminate the directive or the need for a broader plan. The draft MRRMP-E IS's focus on the currently listed species is warranted and should advance their recovery if the AMP is diligently followed, but this sole focus will also come at a cost. If USACE does not identify and implement actions to restore the ecosystem to prevent further declines among other native species, it will ensure further declines and eventually other federally listed species. TNC requests that USACE - in consultation with MRRIC - begin a broader Missouri River ecosystem assessment. Ideally this assessment would fulfill the directive of Section 5018 and evaluate how different levels of restoration of the ecological structure (e.g. riverine/floodplain ecosystem, flow regimes, sediment regimes) can also address and modernize dated aspects of infrastructure and operations associated with the authorized purposes. For example, TNC has long been a proponent of coupling river/floodplain restorations at the known lower river "pinch points". These areas are where at high flows infrastructure located too close to the river increases local river stages. Levees with repetitive failures due to placement over historic river channels are also areas where both ecological and infrastructure restoration could take place. These are just two examples of science-based, practical solutions that meet the needs of people and nature a broader assessment could identify.

Comment Text: A. The Purpose and Need Statement Fails to Provide Guiding Criteria for the Corps to Meet Its Obligations Under the Endangered Species Act. As written, the Corps' purpose and need statement accomplishes three things: it identifies the species requiring protection, states that their protection is mandated by the ESA, and lists nonexclusively three statutes which authorize the Corps to act in pursuit of that protection. The statement is incomplete where it fails to identify what species goals the alternatives will accomplish and how the alternatives will be analyzed. Due to the vagueness of the purpose and need statement, the MRRMP-EIS is permitted to use criteria for the selection of an alternative that have little to do with accomplishing species objectives, and much to do with ensuring that the selected alternative maximizes human consideration interests. To remedy this inadequacy, the Coalitions request that the Corps reformulate its purpose and need statement to efficiently identify the agency's BSA responsibilities and produce an EIS which properly focuses on species objectives.

Comment Text: 2. The Corps should correct the purpose and need statement and produce an environmental impact statement that more efficiently focuses on species goals. To properly redirect the analysis of the MRRMP-EIS towards the purpose of avoiding jeopardy to and restoring the natural viability of the three species, the Coalitions urge the Corps to adopt the following purpose and need statement: The purpose and need of this MRRMP-EIS is to develop a suite of actions to avoid jeopardizing the continued existence of the piping plover, the interior least tern, and the pallid sturgeon in accordance with the Endangered Species Act and other Congressional directives mandating the protection and restoration of the ecological health of the Missouri River. To avoid jeopardy and secure the long-term natural viability of the three species, each alternative set of management actions must at minimum accomplish the following species objectives: Pallid sturgeon: increase recruitment to age 1 and maintain or increase numbers of age 2 and older until sufficient and sustained natural recruitment occurs. Piping plover: maintain and increase a geographically distributed population with a modeled 95% probability that at least 50 individuals will persist for at least 50 years in both Regions. Interior least tern: it is assumed that achieving the stated objectives for the piping plover would also achieve ESA goals for the interior least tern. 24 Management actions utilized to meet this purpose and need include but are not limited to: mechanically and flow-created emergent sandbar habitat, construction of early life stage habitat, habitat-forming seasonal flow releases, floodplain reconnection, and a robust adaptive management plan.

Comment Text: B. Even if the MRRMP-EIS Gives Proper Weight to Human Considerations, the Purpose and Need Statement Does Not Provide the Public an Honest Description of the Project's Goals. Despite the weight given to the economic impacts on human considerations in the selection of a preferred alternative, the term "human considerations" is mentioned merely once in the Executive Summary- not in either the "Need for the Plan" or "Purpose for the Plan" sections but near the end of the Executive Summary under the heading "Implementation of Preferred Alternative under Adaptive Management." Later in the MRRMP-EIS, the "Problem Definition" section adds to the "suite of actions" language that the plan "continues to serve the Missouri River authorized purposes and accounts for human considerations." Then in Chapter 4 on implementation of the preferred alternative (about 800 pages into the MRRMP-EIS), the Corps plainly states: "[m]inimizing impacts on HC while fulfilling the requirements of the ESA is an objective of the [MRRMP-EIS]." Even assuming the Corps grants permissible weight to the expansive range of human considerations in the selection of a preferred alternative, the Corps should more candidly acknowledge that weight in its purpose and need statement. The Corps' failure to identify human considerations as a component of its purpose and need statement misleads members of the public into believing that the analysis focuses primarily on alternative means of restoring the viability of the three species, when in fact the analysis attempts to meet species goals through alternative ways of minimizing human consideration impacts. For the MRRMP-EIS as currently structured to comply with NEPA, the Coalitions propose that the Corps modify the purpose and need statement to the following: The purpose and need of this MRRMP-EIS is to develop a suite of actions that potentially meet ESA responsibilities for the piping plover, the interior least tern, and the pallid sturgeon while reducing federal program expenditures and minimizing economic impacts to stakeholders. This version of the statement adequately reflects the uncertainty of the MRRMP-EIS in meeting BSA obligations and is sufficiently expansive to show the balancing test which the MRRMP-EIS conducts regarding species goals, program expenditures, and human considerations. While the Coalitions urge the Corps to adopt the purpose and need statement suggested in part (A)(2) of this section and thereby narrow the scope of the MRRMP-EIS's analysis to focus on species objectives, this alternative version of the statement is offered to demonstrate how the Corps can more candidly acknowledge the scope of the MRRMP-EIS as it is currently structured.

Comment Text: It is ironic that the Corps did not seem to protest the loss of MRAPS, and yet later spend so much time and money into promoting and developing the Human Considerations filter through which all considerations for DEIS alternatives had to successfully pass. Though never referred to as such, the Human Considerations (HC) are really the Authorized Uses and close outgrowths from them. The Corps has placed so much emphasis upon them and spent considerable manpower and money, for example: contracts with a facilitating company to develop the HCs, another company to help figure-out criteria for them, countless sessions in MRRIC and work group calls, development of proxies and proxy voting, and more. All hypotheses and management actions considered for the prevention of jeopardy of the species had to be evaluated for impact on all Human Considerations and if certain HCs were slightly impacted, the management action (i.e., habitat improvement) was dropped. The question remains: Why did the USACE wish to develop the Human Considerations to such an extent and over-reach in their weight in this EIS effort?

Comment Text: The Authorized Uses in the 1944 Flood Control Act served as the human considerations for the Act. From a legal standpoint, the 8 authorized uses were the means to address the human needs and uses of the river. Irrigation never materialized, nor navigation on the IA-NE reach of the river (except for a small surge in the 1970s), which shows that times change and assumptions made in one era may not have an application many decades later. To have the Authorized Uses, and then to double-whammy them with Human Considerations, is an injustice to the potential habitat and species recovery management actions that are diminished or eliminated because of them. In evaluating the DEIS, it is clear that impacts to HCs are the big hurdle that any and all management actions have to pass through. It appears that HC are driving the decision-making. The DEIS does not explain the weighting of criteria nor the degree to which the Corps is using HC to prioritize. It seems that any recovery management action must not infringe, or cause impediments, on any HC. It would appear that this serves as an escape hatch for the Corps to avoid doing an environmentally favorable alternative or any an action for which certain interest groups oppose.

Comment Text: 5) A holistic watershed approach should be a core component of the EIS - Tributaries should be considered in the EIS and in Alternatives Development, including Fort Peck. According to the EIS, five dams were deemed critical to the success of the upper Missouri reservoir modeling effort. The Corps modeled non-Corps managed dams, including: Canyon Ferry Dam, Tiber Dam, Buffalo Bill Dam, Boysen Dam, and Yellowtail Dam.³⁹ However, the EIS excludes these reservoirs from the development of alternatives. In addition and perhaps even more important, the Corps excludes Fort Peck reservoir from the development of alternatives, even with its importance to the survival of the pallid sturgeon. The Adaptive Management Plan states the geographic scope includes those portions the Great Plains Management Unit (GPMU) below Fort Peck Lake, stating the Corps has jeopardy responsibilities for pallid sturgeon in this portion of the river. The need to address areas of the river above Fort Peck and to include additional tributaries in the EIS are stated in the section below. Further they could be better supported through the designation of critical habitat within these sections to include habitat that support prey species and address the influence of reservoirs on anoxic conditions.

Comment Text: Management actions should be designed to support native prey species. Tributaries and side channels in the Missouri River watershed provide some of the best natural flows, water temperature regulation, and water quality regulation in the basin.⁴⁰ Of 85 species studied in the basin, 77 spawn in tributaries of the Missouri River, while 25 spawn in tributaries or the mainstem.⁴¹ These habitats serve as refugia for juvenile fish and provide water quality benefits such as warm water, turbidity, and preferred substrate.⁴² Sediment input from these tributaries, now lacking due to dam construction, is important to fisheries and in providing sediment to develop or augment sandbars and in-channel islands.⁴³ ⁴⁴ Essentially, without tributary habitat, the prey species the pallid sturgeon depends on would disappear. A holistic watershed-based approach should quantify the habitat needs of important prey species as well as the pallid sturgeon and develop management actions to enhance habitat for the most important prey species.

Comment Text: Historically, the pallid sturgeon has been documented in both the Upper Missouri and Yellowstone rivers in Montana and has been found in tributaries such as the Milk River and Tongue River. Currently, SO wild adult pallid sturgeon are estimated to exist in the Missouri River upstream of Fort Peck Reservoir⁵¹ and 125 wild pallid sturgeon remain in the Missouri downstream of Fort Peck Dam to the headwaters of Lake Sakakawea as well as the lower Yellowstone River.⁵² Additionally, during high flow events, pallid sturgeon have been found in the Matias River, stressing the importance of maintaining access to additional river miles for this species.⁵³ RPM.A #1 above Fort Peck reservoir is an important reach for the maintenance of genetic diversity for the pallid sturgeon. The Bureau of Reclamation states this area "is considered a 'heritage' population because of its relative genetic purity and large body size." The geographical range of the DEIS should include the reach of the Missouri River above Fort Peck Reservoir since this reach of river is designated as Recovery Priority Management Area 1. The reservoir is operated by the Corps and efforts to alter operations downstream of the reservoir will ultimately impact immediately upstream of the reservoir.

Comment Text: None of the alternatives in the EIS support IRC construction in the upper river segments. However, the conceptual model for the pallid sturgeon in the upper river support "Optimization of spawning patches to increase retention of newly hatched free embryos or reconstruction of channel morphology to enhance interception of drifting free embryos could serve to decrease time and distance in the drifting stage, in either river." Additionally, the development of the conceptual model states that floodplain and lateral connectivity are "critical" to creating food resources for pallid sturgeon and possibly to increase retention of young pallid. The EIS provides evidence that drift distance is important for pallid sturgeon embryos in the Yellowstone and Upper Missouri rivers. Given the importance of pallid sturgeon recovery in the upper river, the Corps should consider testing and implementing IRC habitat in the upper river, which could enhance hydraulic roughness and slow down drift of embryos and potentially provide additional food for young of year pallid.

Comment Text: Section & Page Number: 1.5.2, p. 1-23 Comment: The geographic scope for the piping plover is described as the Missouri River from Fort Peck Lake, MT to Fort Randall Dam, SD (Northern Rivers Region); and the Missouri River from Fort Randall Dam, SD to Ponca, NE (Southern Rivers Region). The U.S. Geological Survey is conducting a piping plover metapopulation study. The study evaluates the degree of connection between certain breeding regions, mainly the connection between Lake Sakakawea, Lake Oahe, Garrison Reach, and the alkali lakes in Montana, North Dakota, and South Dakota. Understanding the degree of connection between the breeding areas is critical because bird abundance in one area may be substantially affected by movement between areas. The state strongly supports this study as it will improve future population modeling efforts and provide a better understanding of actions to implement for the recovery of the piping plover. The USFWS and USACE should not confine the geographic scope for the piping plover to the mainstem Missouri River only, but also consider other habitat (i.e. non-ESH habitat) to assist in achieving their goals. If science confirms that there is a significant connection between the Missouri River and alkali lakes, we request consideration of implementing actions in the alkali lakes region to help achieve the Missouri River goals.

Comment Text: The Platte River, referenced in the DEIS (AMP 2-page 320), is utilized by pallid sturgeon and the spawning information from the Platte River could be very beneficial to the recovery of the pallid sturgeon on the lower Missouri River. We are disappointed that the Platte as well as the other tributaries are not within the geographic scope of the MRRMP. We believe the proposed alternatives and recovery actions are too narrow. Key tributaries should be included, as intended by the Missouri River Ecosystem Recovery Plan (MRERP). The Missouri River is a complex ecosystem. The condition of the tributaries is part of the problem so we strongly believe it needs to be included in the recovery of the Missouri River.

Comment Text: And this is something that also is not mentioned. These rises help to replicate natural rises in the river and helps actually by filling these backwaters for other native species that are not being included in this, which is something that has been mentioned this evening, that we are only doing this whole plan for three species and all the others, such as the 67 native fish species which are declining or have gone, will not necessarily get any benefit. None of the plan is intended for other species.

Comment Text: It is the Corps' responsibility within the Mitigation Authority to acquire additional habitat dedicated to all Missouri River channel and floodplain native species. As stated in the executive summary, "the Missouri River and its floodplain have historically consisted of a multitude of aquatic and terrestrial habitat types that sustained rich assemblages of fish and wildlife species. These assemblages include species that live year-round within the river and its floodplain as well as migratory species for which the ecosystem provides vital seasonal habitat (e.g., wintering and breeding), movement corridors, and stopover habitats. Aquatic habitats generally include open water habitats of varying depths (i.e., main channel, secondary channels and chutes, backwaters, floodplain lakes/oxbows). Terrestrial habitats include emergent wetlands, forests, woodlands, grasslands, and shrublands." We believe the Management Plan and the Environmental Impact Statement should take a more holistic approach as to prevent additional species listings.

Comment Text: More emphasis should be placed on ensuring available empirical information is utilized in the process of evaluating hypotheses and developing alternatives for management and implementation. Working with the State to utilize our expertise and local knowledge of the connected Missouri River Yellowstone River ecosystem would substantially improve the effectiveness of recovery actions and would be far more cost-effective. The Science and Adaptive Management Plan (SAMP) was developed to " ... address the uncertainty associated with potential Pallid Sturgeon limiting factors," (p. 1-17, sec. 1.3.1 , Volume 1, MRRMP-EIS). Unfortunately, the document arbitrarily ignores uncertainties associated with attaining successful two-way fish-passage at the Intake Diversion Dam (a structure not operated by the USACE) while postponing needed improvements to Fort Peck Dam operations that are inexplicably deemed infeasible. The predecisional opposition to modify discharge or correct thermal pollution at Fort Peck Dam is surprising, given that the 2003 Biological Opinion (BiOp) clearly states, "In the Upper Missouri River, continued operation of Fort Peck Dam as proposed will continue to significantly impair the reproduction and recruitment of Pallid Sturgeon in this reach. These factors affect the production of forage fish which are important to the overall survival of Pallid Sturgeon," (p. 179, 2003 Amendment to the 2000 BiOp). Selective withdrawal devices are operational at other USACE-operated projects, including Libby Dam in western Montana, and their implementation has greatly benefited the federally-listed Bull Trout and other native fishes. Addressing Pallid Sturgeon limiting factors objectively (e.g., in parallel approach) in the connected Missouri River Yellowstone River ecosystem would serve to more effectively avoid jeopardy to Pallid Sturgeon and would exemplify the" ... demonstrated need to develop a management plan comprised of actions informed by best available science," (p. 1-17, sec. 1.3.1, Volume 1, MRRMP-EIS). As such, the State recommends that the MRRMP-EIS address the Missouri and Yellowstone rivers as connected Pallid Sturgeon habitat and work in parallel to develop alternatives for management and implementation. Specifically, the State requests that efforts to improve Fort Peck

Dam operations for the benefit of Pallid Sturgeon and the downstream Missouri River ecosystem not be conditioned on the success of Pallid Sturgeon passage at Intake Diversion Dam in the MRRMP-EIS.

Comment Text: Additionally, the preferred alternative only commits to Level 1 and 2 research but not to implementation of management actions that adaptive management research demonstrates are required for pallid sturgeon recovery in Montana. If Level 3 and 4 actions are not implemented, no population level changes are to be expected, therefore jeopardy will still exist, as limiting factors are not alleviated or mitigated. It is both biologically unsound and inconsistent with the purpose of the Endangered Species Act for the FWS to not require the Corps to address pallid sturgeon limiting factors in both the Missouri and Yellowstone rivers,

including the reach of the Missouri River upstream of Fort Peck Reservoir which is designated as a recovery priority management area by the FWS.

Comment Text: As a result of the MRRMP-EIS's vague purpose and need statement, the alternatives analysis is permitted to rely on convoluted analyses of human consideration impacts which have no connection to accomplishing species objectives. This dynamic can be witnessed in the first chart of the MRRMP-EIS, which presents the alternatives in comparative form. The chart violates NEPA's requirement to provide the public with meaningful analysis, making it nearly impossible for the public to understand the consequences of the alternatives for the species and for the environment. First, the material in the chart fails to make meaningful

comparisons among the alternatives as they pertain to species objectives. Out of about twenty impact categories listed on the chart, only two are related to the species and both are vague. For the first species criterion, "Addresses Critical EA Pallid Hypothesis," the word "yes" is simply repeated under each alternative's column. This repeated affirmation draws no distinctions among the alternatives regarding their relative effectiveness in accomplishing the pallid sturgeon hypotheses. Likewise, for the criterion "Expected to Meet Revised Bird Targets," the chart repeats the word "meets" for each action alternative besides Alternative 2, which apparently "exceeds" revised bird targets. How Alternative 2 exceeds the bird targets or by how much it exceeds the targets is not indicated.

Comment Text: The Draft EIS states on page 1-1 that the purpose is to avoid jeopardy for the three listed species, whose habitat is degraded by the Corps' Missouri River operations. Nevertheless, the mechanical construction and limited adaptive management prescribed in the preferred alternative are unlikely to avoid jeopardy to the pallid sturgeon. According to USGS, "Results indicate that reproductive readiness and spawning in pallid sturgeon is the result of a complex interaction between internal physiological conditions and environmental factors or 'cues.' Day length and temperature appear to be the most important of the cues that trigger reproductive readiness." (USGS 2010). The data on pallid sturgeon reproduction in the lower Missouri and the upper basin demonstrates limited success. "(R)ecruitment of pallid sturgeon to the adult population is rare or non-existent throughout most of the Missouri River." (USGS 2014). The Corps of Engineers has not demonstrated an ability to influence water temperature in the lower Missouri with releases from the main stem reservoirs, for the range of temperatures required for successful reproduction and survival of pallid sturgeon. Data from USGS and elsewhere indicate that climate influences water temperature in the lower Missouri far more than the release of water from main stem or tributary dams. Mean temperatures of the Missouri River at Sioux City and Omaha tend to be comparable, while temperatures below Nebraska City have averaged 1 degree Fahrenheit cooler, probably due to Platte River inflows, and temperatures increase significantly further downstream. The temperature data undermines the implication that the limited adaptive management contemplated in the Draft EIS will avoid jeopardy.

Comment Text: The current population status of the pallid sturgeon, particularly in the upper 1-issouri River Basin, is tenuous. Most scientific evidence suggests that the decline of the species was caused by the construction of reservoirs along the river by the U.S. Army Corps of Engineers (Corps). Dams have reduced the timing and extent of flows, the drift distance necessary for recently hatched pallid sturgeon, and the spring cues required for the success of the pallid. Current estimates suggest only a few thousand pallid sturgeon remain, fewer than 200 upstream of Lake Sakakawea (including those upstream of Fort Peck Reservoir) and between 2,000 to 4,000 in the Middle Mississippi. A similar species, the shovelnose sturgeon, is also declining and has been extirpated or is at risk of extirpation from parts of its native range. Most of the surviving pallid sturgeon population is stocked, and reproductive adults are rare. Though spawning does occur, recruitment is limited or non-existent in the Missouri and Middle Mississippi Rivers and in the Middle Mississippi River. It is for the above reasons that the Corps should prioritize river restoration and modifications to reservoir operations to support recovery of the pallid sturgeon. The federal agencies believe two key goals would be most relevant to recovery of the pallid sturgeon: -Increase pallid sturgeon recruitment to age 1. -Maintain or increase numbers of pallid sturgeon of age 2 and older until sufficient and sustained natural recruitment occurs.

Comment Text: B. Even if the MRRMP-EIS Gives Proper Weight to Human Considerations, the Purpose and Need Statement Does Not Provide the Public an Honest Description of the Project's Goals. Despite the weight given to the economic impacts on human considerations in the selection of a preferred alternative, the term "human considerations" is mentioned merely once in the Executive Summary- not in either the "Need for the Plan" or "Purpose for the Plan" sections but near the end of the Executive Summary under the heading "Implementation of Preferred Alternative under Adaptive Management." Later in the MRRMP-EIS, the "Problem Definition" section adds to the "suite of actions" language that the plan "continues to serve the Missouri River authorized purposes and accounts for human considerations." Then in Chapter 4 on implementation of the preferred alternative (about 800 pages into the MRRMP-EIS), the Corps plainly states: "[m]inimizing impacts on HC while fulfilling the requirements of the ESA is an objective of the [MRRMP-EIS]." Even assuming the Corps grants permissible weight to the expansive range of human considerations in the selection of a preferred alternative, the Corps should more candidly acknowledge that weight in its purpose and need statement. The Corps' failure to identify human considerations as a component of its purpose and need statement misleads members of the public into believing that the analysis focuses primarily on alternative means of restoring the viability of the three species, when in fact the

analysis attempts to meet species goals through alternative ways of minimizing human consideration impacts. For the MRRMP-EIS as currently structured to comply with NEPA, the Coalitions propose that the Corps modify the purpose and need statement to the following: The purpose and need of this MRRMP-EIS is to develop a suite of actions that potentially meet ESA responsibilities for the piping plover, the interior least tern, and the pallid sturgeon while reducing federal program expenditures and minimizing economic impacts to stakeholders. This version of the statement adequately reflects the uncertainty of the MRRMP-EIS in meeting BSA obligations and is sufficiently expansive to show the balancing test which the MRRMP-EIS conducts regarding species goals, program expenditures, and human considerations. While the Coalitions urge the Corps to adopt the purpose and need statement suggested in part (A)(2) of this section and thereby narrow the scope of the MRRMP-EIS's analysis to focus on species objectives, this alternative version of the statement is offered to demonstrate how the Corps can more candidly acknowledge the scope of the MRRMP-EIS as it is currently structured.

Comment Text: Section 1.5.2, Page 1-24, Sub-Objective 2 - Concerning a 95% modeled probability that at least 50 birds will persist for 50 years (Northern and Southern Regions). Piping plover populations continue to exist on the river with fairly stable or increasing numbers (see 2015 Annual Report) despite the construction of dams on the Missouri River in the 1950s and little or no nesting in on the Missouri River or associated reservoirs in years like 1997 and 2011. Therefore modeling the Missouri as two separate populations that have little or no interaction and holding emigration and immigration as steady and equal in the models obviously does not take into account the reality of the bigger metapopulation influence and has some limitations. How those limitations affect the persistence probability needs to be explained. Likewise if acres of ESH are to be used as a surrogate there should be a simple graph or table that demonstrates the historical relationship of plover populations to acres of ESH in the past to justify the proposed methodology.

Comment Text: Recreation Technical Report Comments The unit day value (UDV) method was used to evaluate National Economic Development (NED) impacts of the alternatives on recreation in the Missouri River basin. This method relied on the opinions of the project managers for assigning points that ultimately determine the unit day value for each reservoir/reach. Additionally, under this method, boating is included in the general recreation category which has a lower range of unit day values than the general fishing category. This is not appropriate for the upper 5 reservoirs, since the majority of boaters are engaging in fishing activity. This highly subjective valuation method may be fine for simply comparing impacts of the different alternatives, but not for weighing impacts between interest groups. We ask that the USAGE utilize the Regional Economic Development (RED) RECON valuation method that is based on expense/revenue data for estimation of economic impact when comparing benefit/loss across multiple interest categories.

Comment Text: As a tribal member of Standing Rock my family has been personally and economically impacted by the development on the Missouri River since the dams were first built. The water rights of the Tribe are being detrimentally impacted by the DEIS. As a member of the tribe I am opposed to mechanical construction in the Oahe reservoir. I am also opposed to the type of development which would impact the water quality or quantity. The water rights and water supply issues directly impact me as a tribal member. The plants, including medicinal and those which are important to the spiritual and cultural lifeways of my people are at high risk due to the development and resulting pollution along the length of the river.

Comment Text: As acknowledged by the Corps on page 3-28 of the Draft EIS, all of the alternatives will adversely impact the water supplies of the Great Plains Water Alliance Tribes in the upper basin. The adverse effect on Tribal water caused by the Recovery Management Plan compounds the impacts caused by Missouri River Master Manual. Neither the current damage nor the compounded harm is recognized or disclosed in the Draft EIS. Accordingly, the true environmental impacts on Tribes are not properly considered by the Corps of Engineers in the Draft EIS.

Comment Text: The current operations under the Master Manual degrade Tribal water supplies and impact the Tribe's ability to put water to beneficial use. The Corps' current operations on the Missouri River also destroys the habitat of the listed species. Yet the stated purpose of the Draft EIS is to continue the status quo in the operation of the Missouri River main stem system under the Master Manual, through the limited adaptive management and mechanical construction prescribed in the preferred alternative. The Draft EIS establishes new demands for water, but proposes no changes to current Missouri River operations under the Master Manual in order to fulfill the increased demand. None of the downstream water users who benefit from the Corps' water management will be impacted. The Corps acknowledges in the Draft EIS that it is Tribal water supplies that will be the source for the downstream fish and wildlife uses that are proposed. (Draft EIS, p. 3-28). The Tribes did not cause the decline of these species, but under the Recovery Management Plan, we pay the price of habitat restoration - however inadequate it may be.

Comment Text: The alternatives in the Draft EIS, in combination with the construction of the main stem dams, the pattern of water releases pursuant to the Master Manual, and the management of Pick-Sloan project lands for oil and gas pipelines, have a significant, adverse and disproportionate impact on the Indian Nations of the Missouri Basin. The adverse impacts include socioeconomic distress and trauma caused by the forced relocation of Tribal communities, as well as the use of Tribal water for the exclusive benefit of non-Indian economies. The adverse effects also include the public health impacts caused by the degradation of drinking water supplies, and the environmental risk caused by the permitting of oil pipelines in Indian lands and waters. Important issues facing the Tribes such as noxious weeds and invasive species on Indian lands caused by the Corps' Missouri River operations are totally ignored in the Draft EIS.

Comment Text: The CEQ regulations require the Corps of Engineers to evaluate the cumulative environmental impact of the proposed action with other past and foreseeable future actions. 40 CFR Â§ 1508. 7. The CEQ requires an "analysis and precise description of identifiable present effects of past actions to the extent that they are relevant and useful in analyzing whether... (the) alternatives may have a continuing, additive and significant relationship to those effects." (Memorandum from James L. Connaughton, Chairman, Council on Environmental Quality, to Heads of Federal Agencies, June 24, 2005). Adequate consideration of the cumulative impacts of agency projects requires "some quantifiable or detailed information" on the overall impacts. (Coggins et al, PUBLIC NATURAL RESOURCES LAW (2Ând ed.) Â§17.35). This is especially important in the Missouri River Basin, where the Pick-Sloan program destroyed Tribal riparian bottomlands along the Missouri liver, and caused adverse impacts to Tribal resources and water supplies on the tributaries to the Missouri. The eminent scholar Vine Deloria, Jr., an enrolled member of the Standing Rock Sioux Tribe, described Pick-Sloan as "the single most destructive act ever perpetuated on any tribe by the United States." (Deloria, Introduction to Michael L. Lawson, DAMMED INDIANS: THE PICK-SLOAN PLAN AND THE MISSOURI BASIN SIOUX, 1944-1980 (1982)). The construction and operation of the dams on the Missouri River and its tributaries in the upper basin have caused extremely significant impacts that must be included in the cumulative impact analysis. The most significant adverse impacts of the Pick-Sloan program were suffered by Tribal communities in the Missouri River bottomlands. The U.S. Senate Committee on Indian Affairs recently reported - ...seven reservations were strategically located along resource-rich the Missouri River. The Missouri River's wooded bottomlands provided the reservation economies with fertile agricultural lands, timber for lumber and fuel. .. seasonal fruits, habitat for wild game, medicines . . . and plentiful supplies of clean water. These lands were also an

important part of the tribes' social, cultural and spiritual lives. Much of the tribes' community infrastructure was located along the river, including tribal homes, schools, hospitals, government buildings, churches, graveyards, and roads... Relocated to the upland plains ... the remaining reservation lands were less suitable for sustaining the Tribes' economic base, including ranching and agriculture, due to poor soil and water quality... (P)romises to compensate the Tribes, in part, with discounted electricity went unfulfilled. (S. Rep. 111-357 (2010), p. 1-2, 4).

Comment Text: There is a cumulative impact to Tribal water supplies in the upper basin, from current Corps' operations under the Master Manual, which will be made worse by the proposed alternatives in the Draft EIS. The Corps admits on page 3-28 that water levels in the upper basin will diminish due to the preferred alternative. As described above, the Corps' current water management violates the Treaty water rights of the Tribes - the added water demands imposed by the Recovery Management Plan will cause cumulative impact to Indian water.

Comment Text: Appendix E to the Draft EIS lists related projects for cumulative impacts analysis. It does identify "Missouri River Mainstem Reservoir System Construction" as a related project for cumulative impact analysis. However, there is no analysis of the extremely harmful impacts the projects have had on Indian land, water and communities. Although the Corps mentions the Missouri River Master Manual, the Draft EIS totally fails to disclose the significant adverse impact of the construction of the dams or the ongoing harm caused by the Master Manual on Indian water. These impacts are very well documented. Lawson, DAMMED INDIANS: THE PICKSLOAN PLAN AND THE MISSOURI BASIN SIOUX, 1944-1980 (1982); Marc Reisner, CADILLAC DESERT: THE AMERICAN WEST AND ITS DISAPPEARING WATER (1986); Peter Capossela, THE LAND ALONG THE RIVER: THE ONGOING SAGA OF THE SIOUX NATION LAND CLAIM, 1851-2012 (2015); Final Report and Recommendations of the Garrison Unit Joint Tribal Advisory Committee: Joint Hearing of the S. Comm. on Indian Affairs., the S, Comm. on Energy and Natural Res., and the H Comm. on Interior and Insular Aff., 100th Cong., (1987); Peter Capossela, Impacts of the Army Corps of Engineers' Pick-Sloan Plan on the Indian Tribes of the Missouri River Basin, J. ENV'T'L LA w AND LIT. 30:143 (2015); John H. Davidson, Indian

Water Rights, the Missouri River and the Administrative Process: What are the Questions? AMERICAN INDIAN L. REV. 1 (2000). Yet the Corps fails to disclose or analyze them in the Draft EIS.

Comment Text: There is a cumulative socioeconomic impact as well. The historical costs of the destruction of Tribal land, resources and life ways in the inundated bottomlands remains unresolved. (S. Rep. 111-357, a Report on the Pick-Sloan Tribal Commission Act). In recent years, Tribes have had to expend millions of dollars to expand and rehabilitate drinking water and irrigation intakes on the Missouri River, due to diminished water elevations caused by water releases by the Corps for downstream navigation. (Missouri River Master Manual: Hearing Before the Committee on Indian Affairs, US. Senate, 108th Cong. (2003)). The Corps acknowledges that Tribes will incur increased costs to access water in the future, upon implementation of the alternatives in the Draft EIS. (Draft EIS, p. 3-28). These cumulative adverse impacts on Tribal economies must be disclosed and considered by the Corps.

Comment Text: Appendix E also identifies "Oil and Natural Gas Production" as a related project to the Recovery Management Plan. The cumulative impacts summarized in Table 3-1 identify oil and gas production as a related cumulative action affecting Tribes. However, the approval of the Dakota Access Pipeline and the Presidential Permit for the Keystone XL Pipeline pose significant environmental risk to the Missouri River, and there is no quantitative analysis of this risk. Table 3-1 simply is not an adequate disclosure of the cumulative impacts of oil and gas pipelines and the Recovery Management Plan on the Tribes.

Comment Text: The Draft EIS states "For this analysis, the state and/or county in which the block group is located were used as the reference area. Therefore, census block groups whose minority population is ten percentage points higher than the state or county average... are identified as environmental justice populations." " (p. 3-563-3-564). The Corps may have performed an analysis of impacts on minority populations, but failed to do so on Tribes, as required in the CEQ Guidance. Moreover, the impacts assessment methodology "qualitatively" evaluated whether there are disproportionate impacts on minority communities, using the general impacts analysis. Since the general impacts analysis fails to identify Pick-Sloan's impact on Indian land and water, the assumptions used in the qualitative analysis are incorrect, and the conclusions in the Draft EIS with respect to Tribal impacts are erroneous.

Comment Text: The negative impacts experienced by Tribes far exceeds any negative impacts on non-Indian communities, because the Corps of Engineers located the main stem reservoirs in Indian Country, and the Bureau of Reclamation projects adversely impact Tribal waters and resources on the tributaries. With respect to overall "Human Considerations," Tribal impacts are not given sufficient weight as compared to "agriculture, irrigation, hydropower, local government, navigation, recreation " (Draft EIS, p. 3-5). For example, the Human Considerations analysis suggests that the destruction of Tribal resources is on a par with the inconvenience fishermen may face due to habitat restoration. The Human Conditions analysis totally downplays Tribal concerns with the disproportionate and long-term negative impacts suffered by the Tribes.

Correspondence Id: 232 **Comment Id:** 645357 **Coder Name:** jgutierrez

Comment Text: The entire study area of the Draft EIS is within the Treaty and aboriginal boundaries of the Great Plains Water Alliance Tribes. The habitat for the least tern, piping plover and pallid sturgeon that has been destroyed by the Missouri Basin Pick-Sloan program, was Treaty land and water. The Draft EIS totally ignores the Treaty rights of the Great Plains Tribal Water Alliance. "Agencies shall respect Indian self government and sovereignty, honor treaty and other rights, and strive to meet the responsibilities that that arise from the unique legal relationship between the Federal Government and Indian tribal governments." Executive Order 13175 (65 Fed. Reg. 67250). The requirement to honor Treaty rights applies to the Corps of Engineers with the Recovery Management Plan. Consequently, the Draft EIS must include a description of the Indian Treaty rights in the study area, and describe how the Corps of Engineer will comply with the dictates of Executive Order 13175 to honor Treaty rights. It fails to do so.

Correspondence Id: 232 **Comment Id:** 645414 **Coder Name:** jgutierrez

Comment Text: The study area is Lakota and Dakota Treaty and aboriginal land. Article II of the Fort Laramie Treaty of April 29, 1868, established the Great Sioux Reservation as follows: The United States agrees that the following district of country, to wit, viz: commencing on the east bank of the Missouri river where the 46th parallel of north latitude crosses the same, thence along low-water mark down said east bank to a point opposite where the northern line of the State of Nebraska strikes the river, thence west across said river, and along the northern line of Nebraska to the 104th degree of longitude west from Greenwich, thence north on said meridian to a point where the 46th parallel of north latitude intercepts the same, thence due east along said parallel to the place of beginning; and in addition thereto, all existing reservations of the east back of said river, shall be and the same is, set apart for the absolute and undisturbed use and occupation of the Indians herein named, and for such other friendly tribes or individual Indians as from time to time they may be willing, with the consent of the United States, to admit amongst them; and the United States now solemnly agrees that no persons, except those herein designated and authorized so to do, and except such officers, agents, and employees of the government as may be authorized to enter upon Indian reservations in discharge of duties enjoined by law, shall ever be permitted to pass over, settle upon, or reside in the territory described in this article. (15 Stat. 635). Thus, our Treaty Reservation comprised of all present-day South Dakota west of the Missouri River. The low water mark of the east bank is the Reservation's eastern boundary - placing the Missouri River within the exterior boundaries of the Great Sioux Reservation. Under Article XVI of the 1868 Fort Laramie Treaty, the Sioux Nation retained aboriginal lands previously recognized as Sioux territory in the 1851 Fort Laramie Treaty -

The United States hereby agrees and stipulates that the country north of the North Platte river and east of the summits of the Big Horn mountains shall be held and considered to be unceded Indian territory, and also stipulates and agrees that no white person or persons shall be permitted to settle upon or occupy any portion of the same; or without the consent of the Indians, first had and obtained, to pass through the same. (15 Stat. 639).

Comment Text: The right of Tribes to government-to-government consultation is also a Treaty right. Article XI of the 1868 Fort Laramie Treaty explicitly contemplates consultation in the development of "works of utility or necessity, which may be permitted by the laws of the United States." (15 Stat. 638). The Draft EIS contains rhetoric with respect to Tribal consultation; however, it makes no mention of Article XI, or of any other Treaty rights of our Tribes. The Treaty right of consultation is to be implemented pursuant

to Executive Order 13175 on Consultation and Coordination with Indian Tribal Governments. Under E.O. 13175, the Corps of Engineers must - ... work with Indian tribes on a government-to-government basis to address issues concerning Indian tribal self government, tribal trust resources (and) Indian tribal treaty rights ... Each agency shall have an accountable process to ensure meaningful and timely input by tribal officials in the development of regulatory policies ... (65 Fed. Reg. 67249-67250). The term "meaningful" suggests that Tribal views will be incorporated into the decision-making process. The term "timely" requires that Tribal views be solicited at the beginning of the decision-making process. With respect to the Draft EIS, the Corps of Engineers did none of this. The Corps' inaction speaks for itself. Form letters were sent to the Tribes on October 20, 2016 and December 16, 2016, inviting consultation. The Draft EIS and preferred alternative were published on December 16, 2016. The consultation process was not initiated in a timely manner. All alternatives were selected, the preferred alternative was identified, and the environmental impacts were supposedly evaluated before government-to-government consultation was even initiated. The Draft EIS explains on page 5-4 that "The intent of government-to-government consultation is to provide for identification and resolution of issues relating to the alternatives being evaluated in this draft EIS." That demonstrates the lack of timely consultation for the selection of the alternatives.

Comment Text: Appendix H to the Draft EIS includes a list of meetings identified as "Alternatives Development Meetings," with the names of Tribes and dates of meetings. The Draft EIS contains no record of the participants or the discussions - the list is meaningless and does not demonstrate that Tribal concerns were included in the alternatives. Significantly, the Oglala Sioux Tribe Natural Resources Regulatory Agency documented the discussion referenced "7/11/2016 - Oglala Sioux Tribe." Tribal meeting minutes reveal that there was no discussion of the alternatives to be published in the Draft EIS. The description by the Corps of the July 11, 2016 meeting with the Oglala Sioux Tribe as an "Alternatives Development Meeting" is false. The veracity of the entire list of "Alternatives Development Meetings" must be questioned.

Comment Text: The Draft EIS states on page 2-1 , "An interdisciplinary planning team made up of experts from multiple federal agencies in collaboration with basin stakeholders and Tribes participated in alternatives development." The "interdisciplinary

planning team" never met with any of the Tribal governments of the Great Plains Water Alliance. There was no government-to-government consultation with any Tribes on the Draft EIS.

Comment Text: The narrative in the Draft EIS combines Tribal consultation with "Agency and Public Involvement" and implies that MRRIC substitutes for compliance with the government-to-government consultation requirements in E.O. 13175. (Draft EIS, p. 5-1). MRRIC is a collaborative stakeholder group with which the Great Plains Alliance Tribes have cooperated. The implication that good faith Tribal participation in region-wide collaborative processes satisfies the Tribal consultation requirement is wrong and will discourage Tribal participation in the future. The Corps of Engineers should not make false statements in a Draft EIS about what was discussed in meetings, and should not misportray stakeholder discussions as Tribal consultation.

Comment Text: Ultimately, the lack of government-to-government consultation in the preparation of the Recovery Management Plan is evidenced by the fact that none of the Tribes' concerns are addressed in the plan. For example, Appendix E of the Draft EIS identifies "Special Status Species" of the states of Montana, North Dakota, South Dakota, Nebraska, Iowa, Kansas and Missouri. The Tribes have identified riparian plant species of extreme concern, due to historical medicinal and nutritional uses of these species. However, these species are not identified in the Draft EIS. Species of concern to the states are included, but species of concern to the Tribes are totally ignored. Had the Corps of Engineers consulted with the Tribal governments, this important information would be disclosed in the Draft EIS and the impacts to these resources properly evaluated. Instead, Corps merely continued the longstanding practice of the Omaha District to engage Tribes as a formality, only after decisions have been made.

Comment Text: The Draft EIS violates section 106 of National Historic Preservation Act because (1) the surveys of cultural sites utilized for the impacts analysis are outdated and incomplete; (2) the Corps failed to consult with the THPOs on traditional cultural properties, and the Corps' NHPA section 106 procedures in Appendix C violate the Advisory Council requirements at 36 CFR Part 800; and (3) the assumptions in the computer model are flawed. The Tribes of the Great Plains Water Alliance administer Secretariaily-approved Historic Preservation Offices pursuant to section 101 of the National Historic Preservation Act. 54 U.S.C. Â§302702. Accordingly, our THPOs must be consulted on the direct and indirect impacts on traditional cultural properties of the alternatives in the draft EIS, as well as their cumulative impact with other Corps programs, including the Missouri River Master Water Control Manual. The Corps of Engineers has not done so. The Corps' procedures for implementing the NHP A section 106 consultation requirement are widely viewed as violating the applicable regulations of the Advisory Council on Historic Preservation, in any event.

Comment Text: Federal agencies should be aware that frequently historic properties of religious and cultural significance are located on ancestral, aboriginal, or ceded lands of Indian tribes or Native Hawaiian organizations and should consider that when complying with this part. 36 CFR Â§800.2(c)(2)(ii)(D). None of this has occurred. The surveys used for the computer models are outdated, and were not conducted in compliance with the consultation requirements for traditional cultural properties. 36 CFR Â§800.2(c)(2)(ii). The Great Plains Water Alliance Tribes are not signatories to the Missouri River Programmatic Agreement, and thus full compliance with section 106 and the implementing regulations at 36 CFR Part 800 is mandatory. The Corps has not done so with respect to the Draft EIS. The Corps admitted this on page 8 of the Technical Report - It is understood that there are many unknown cultural resource

sites existing on the landscape, as well as important cultural resources that do not meet the definition of a cultural resources site used in this study. The inventory of known cultural resource sites used in this analysis is intended to serve as a representative sample. That does not constitute compliance with the identification requirements of 36 CFR 36 CFR Â§800.2-800.5. Consequently, the Draft EIS violates the National Historic Preservation Act and its implementing regulations. The Advisory Council permits agencies such as the Corps to develop agency specific procedures for NHPA section 106, "if they are consistent with the Council's regulations." 36 CFR Â§800.14(a). The Corps has promulgated section 106 procedures which are codified at 33 CFR Part 325 App. C. The Corps' section 106 procedures are widely considered to violate 36 CFR Part 800.

Comment Text: According to the Advisory Council - Appendix C is not approved by the ACHP as a program alternative, as required by 36 CFR Â§800.14. Therefore, the ACHP considers Appendix C as an internal Corps process that does not fulfill the requirements of Section 106 of the NHP A... (T)his arrangement often leads to the Corps' failure to adequately consult with federally recognized Tribes regarding the identification of, and assessment of effects on, historic properties of religious and cultural significance. (Letter of Reid J. Nelson, Advisory Council on Historic Preservation, to David B. Olson, U.S. Army Corps of Engineers, August 1, 2016). That is exactly what has happened with the Draft EIS for the Recovery Management Plan.

Comment Text: In sum, the Corps has failed to comply with the required process under NHP A section 106. The findings in the Draft EIS are based on false or incomplete assumptions used in the determination of impacts to cultural resources. The Draft EIS is fatally flawed for lack of compliance with the National Historic Preservation Act and its implementing regulations.

Comment Text: For its part the CEQ has issued Guidance on determining the impacts of agency actions on minority and Tribal communities. The CEQ Guidance emphasizes the need for Tribal community involvement in scoping - If an agency identifies any potentially affected ... Indian tribes, the agency should develop a strategy for effective public involvement in the agency's determination of the scope of the NEPA analysis. Customary agency practices for notifying the public of a proposed action and subsequent scoping and public events may be enhanced through better use of local resources, community and nongovernmental organizations, and locally targeted media. Agencies should consider enhancing their outreach through the following means: Religious organizations; Newspaper, radio and other media, particularly media targeted to... Indian tribes... Minority business associations; Legal aid providers... Tribal governments... Community and social services organizations; Universities, colleges, vocational and other schools... Public health agencies and clinics... (Council on Environmental Quality, Environmental Justice: Guidance Under the National Environmental Policy Act (1997), p. 11). The Corps of Engineers has done none of this. The CEQ Guidance makes clear that environmental impacts on Tribal communities require rigorous scoping efforts. The Guidance outlines the steps to be taken for scoping on Indian Reservations. The Draft EIS contains erroneous information on the impacts of the Pick-Sloan program and Recovery Management Plan on Tribes, in part because the Corps never conducted the required scoping as prescribed in the CEQ Guidance. The lack of adequate scoping in Tribal communities, as well as the lack of government-to-government consultation with Tribes, necessitates an extension to the public comment period on the Draft EIS. The Great Plains Tribal Water Alliance hereby calls upon the Corps of Engineers to reopen and extend the public comment on the Draft EIS for an additional 90 days.

WSTR100 Water Supply Technical Report: General Comments (Substantive)

Correspondence Id: 32 **Comment Id:** 627964 **Coder Name:** jgutierrez

Comment Text: We had considered - - we have concerns about the information provided in the Water Supply technical memo. The information presented in this memo has a lot of the members in the association asking more questions as to where the Corps obtained their data. The information on the size of pumps and costs necessary to draw the water from the river seems to be underestimated. Trying to locate large pumps larger than 7,000 gallons a minute to rent would be a difficult task, especially if half the members of this association must find these large pumps. Some of the information presented seems to be grossly underestimating the impact if the water supplies are not able to have access to the river. The size of the pumps necessary to draw water and costs associated with finding large enough pumps to operate. The water supplies in this association service over 4 million customers, and billions in industrial commerce and services which depend on the water from the Missouri River. We do not feel this technical memo allows for the seven recommended actions made by the MRRIC in 2012 to evaluate the effects analysis.

Comment Text: Some of the key concerns we have are the Human Consideration Technical Report on the water supply is inconsistent in assessing risk, presuming the worst case for flows, but often the best case for water utility ability to respond. Not all low water conditions could be solved using submersible pumps. This is not a reasonable assumption. The idea that pumps could be rented by all utilities in a low water situation is unreasonable. Low water affects too many utilities at one time for all utilities to be able to rent pumps. For larger utilities such as WaterOne, it is unlikely that large enough pumps could be rented to meet the supply needs available - could be - - to meet the supply needs will be available to us. The assumption of the report is unrealistic and should be modified. The report failed to consider that at low water some utilities may have to lay miles of pipe just to reach the water supply. When the reservoirs get low, whole arms of the lake have dried up in the past. The river channel could also migrate away from the intake, and these costs should be considered in the report.

Comment Text: I would like to reference the Human Considerations Technical Report- Water Supply, Section 3.1, Paragraph 2, which uses the Period of Record along with the minimum flow per the Master Manual as the flow condition. This worst case model scenario also does not include how often the scenario occurs. For example, does it include - - does it occur once every year or once every 25 years? The frequency of those occurrences and the associated costs should be included in the report.
