

Benefits of Fire

You've seen the stories on television, read the newspaper headlines that blazed about the devastation caused by wildfires, but as a visitor to the national parks, that plume of smoke you see towering over the trees may be from a fire benefitting not only the land, but you as a park visitor.

Great Smoky Mountains National Park,
Tennessee and North Carolina

North Cascades National Park,
Washington

Yosemite National Park, California

During your park visit do you hope to see healthy wildlife, open panoramic vistas, forests penetrated by sunlight, or verdant grasslands? If so, then wildland fire was also likely part of that picture whether you knew it or not.

Many parks across the country, from Great Smoky Mountains National Park in Tennessee to North Cascades National Park in Washington State, use fires started by lightning to reduce fuels, provide wildlife habitat, and restore native species.

Why does fire need to be a part of the picture?

From 1872 when Yellowstone became the world's first national park until the mid-twentieth century, land managers were dedicated to stopping what they saw as destruction of forests by fire. While some scientists and land managers had recognized the value of fire on the land and advocated its use, it was not until the 1960s that this view resulted in a change of National Park Service policy.

Fire is part of a cycle in most ecosystems. It reduces dead vegetation, stimulates new growth, and improves habitat for wildlife, many of the details park visitors imagine when they think of a national park. With fire suppression, fire was removed from the cycle and ecosystems began to get out of balance.

After nearly a century of no fires, fuels, such as dead trees, pine needles, leaf litter, and shrubs built up to unnatural levels in forests. In these cases, restoring fire is no easy task; sometimes it takes additional work such as manual removal of the debris before the fire cycle can begin again.

Fire, such as this one at Grand Canyon National Park, helps to clear the forest floor of debris or fuel and encourages new growth.

Are there any firefighters on the fire?

It depends. Every human-caused fire is suppressed, and a natural fire could be suppressed by firefighters if it is too close to park infrastructure or a community. When it is not, it is regularly monitored and assessed to assure that it meets and continues to meet objectives pre-set by park and fire managers. Some fires that are burning in very remote parts of a park where there will be no impact to human life and safety may only be monitored by plane every few days. Other fires may need more active management – point protection for structures, cooling the fire in certain areas, burning out large amounts of fuel in other areas. On these fires, firefighters may camp out close to the fire for several days as they are still typically remote from park infrastructure. To learn more, talk to a park employee.

How will the fire impact my visit to the park?

Most likely you will see smoke during your visit. Depending upon weather conditions, the smoke may come into visitor areas and surrounding communities. If smoke becomes too extreme and

Smoke may appear as a large billowy cloud on the horizon or obscure the view during your visit.

In times of low fire activity, visitors are sometimes allowed through a fire area. Check with park staff regarding the safety of entering any fire area.

At times fire managers burn vegetation in front of the fire to create a buffer.

impacts visitors and nearby communities, fire managers may cool areas of the fire with water.

If the fire is burning in an area where there is a trail, fire managers and park managers will decide whether to allow visitors to pass through a fire area. When the fire is very active, the trail may be closed; however, in times of low activity visitors may be escorted through a fire area or be allowed to go through on their own. They must remain on the trail and not report or put out the fire that may be burning near the trail.

How does a park decide how to manage a wildfire?

A park must have an approved fire management plan in place or all wildfires will be suppressed. Even then, park and fire managers must evaluate each fire that starts as to whether it should be allowed to burn or be suppressed. Each park is different in specifying when, where, and under what conditions a wildfire will be managed. Any wildland fire that has the potential to threaten human life or safety will be suppressed. Some parks adjoining lands owned by other agencies (i.e. Forest Service, Bureau of Land Management) work together to have a wildfire cross jurisdictional boundaries. Other times, if wildfire is not permitted on adjoining land owned by another agency, the fire is suppressed near the boundary.

During a wildfire, managers may choose to steer the fire away from certain areas by digging fireline or burning vegetation in advance of the fire to create a buffer. These targeted actions protect special resources or reduce smoke emissions in specific areas while still allowing beneficial fire spread in other areas. If conditions change and it is decided that the fire is no longer achieving the objectives, it may be put out.

How long will the fire burn?

Depending on many factors, wildfires may burn from early summer into the fall when seasonal rain, snow and lower temperatures put it out. Fire activity can vary depending upon the type and amount of vegetation, terrain, temperature, and moisture. Fire size can also vary, from less than one-acre to several thousand acres. It all depends upon the continuity of burnable vegetation, weather patterns, and management objectives for the fire. As conditions change, the fire may go from a smoldering surface fire to

flames that roar through the tops of the trees. As with all management of fires, public education is important, especially when the fire or the smoke produced has the potential to impact nearby communities.

Conclusion

Fire is a jolt to living systems, the beginning of a new state of life on the land which is part of a cycle that has been in place for thousands of years. For the National Park Service, fire is used as an important management tool which enables it to continue its natural role on the landscape.
